Let \( K \) denote the functor of complex \( K \)-theory, which associates to every compact Hausdorff space \( X \) the Grothendieck group \( K(X) \) of isomorphism classes of complex vector bundles on \( X \). The functor \( X \mapsto K(X) \) is an example of a cohomology theory: that is, one can define more generally a sequence of abelian groups \( \{K^n(X, Y)\}_{n \in \mathbb{Z}} \) for every inclusion of topological spaces \( Y \subseteq X \), in such a way that the Eilenberg-Steenrod axioms are satisfied (see [49]). However, the functor \( K \) is endowed with even more structure: for every topological space \( X \), the abelian group \( K(X) \) has the structure of a commutative ring (when \( X \) is compact, the multiplication on \( K(X) \) is induced by the operation of tensor product of complex vector bundles). One would like that the ring structure on \( K(X) \) is a reflection of the fact that \( K \) itself has a ring structure, in a suitable setting.

To analyze the problem in greater detail, we observe that the functor \( X \mapsto K(X) \) is representable. That is, there exists a topological space \( Z = \mathbb{Z} \times BU \) and a universal class \( \eta \in K(Z) \), such that for every sufficiently nice topological space \( X \), the pullback of \( \eta \) induces a bijection \( [X, Z] \to K(X) \); here \( [X, Z] \) denotes the set of homotopy classes of maps from \( X \) into \( Z \). According to Yoneda’s lemma, this property determines the space \( Z \) up to homotopy equivalence. Moreover, since the functor \( X \mapsto K(X) \) takes values in the category of commutative rings, the topological space \( Z \) is automatically a commutative ring object in the homotopy category \( \mathcal{H} \) of topological spaces. That is, there exist addition and multiplication maps \( Z \times Z \to Z \), such that all of the usual ring axioms are satisfied up to homotopy. Unfortunately, this observation is not very useful. We would like to have a robust generalization of classical algebra which includes a good theory of modules, constructions like localization and completion, and so forth. The homotopy category \( \mathcal{H} \) is too poorly behaved to support such a theory.

An alternate possibility is to work with commutative ring objects in the category of topological spaces itself: that is, to require the ring axioms to hold “on the nose” and not just up to homotopy. Although this does lead to a reasonable generalization of classical commutative algebra, it not sufficiently general for many purposes. For example, if \( Z \) is a topological commutative ring, then one can always extend the functor \( X \mapsto [X, Z] \) to a cohomology theory. However, this cohomology theory is not very interesting: in degree zero, it simply gives the following variant of classical cohomology:

\[
\prod_{n \geq 0} H^n(X; \pi_n Z).
\]

In particular, complex \( K \)-theory cannot be obtained in this way. In other words, the \( Z = \mathbb{Z} \times BU \) for stable vector bundles cannot be equipped with the structure of a topological commutative ring. This reflects the fact that complex vector bundles on a space \( X \) form a category, rather than just a set. The direct sum and tensor product operation on complex vector bundles satisfy the ring axioms, such as the distributive law

\[
\mathcal{E} \otimes (\mathcal{F} \oplus \mathcal{F}') \simeq (\mathcal{E} \otimes \mathcal{F}) \oplus (\mathcal{E} \otimes \mathcal{F}'),
\]

but only up to isomorphism. However, although \( \mathbb{Z} \times BU \) has less structure than a commutative ring, it has more structure than simply a commutative ring object in the homotopy category \( \mathcal{H} \), because the isomorphism displayed above is actually canonical and satisfies certain coherence conditions (see [91] for a discussion).

To describe the kind of structure which exists on the topological space \( \mathbb{Z} \times BU \), it is convenient to introduce the language of commutative ring spectra, or, as we will call them, \( E_\infty \)-rings. Roughly speaking, an \( E_\infty \)-ring can be thought of as a space \( Z \) which is equipped with an addition and a multiplication for which the axioms for a commutative ring hold not only up to homotopy, but up to coherent homotopy. The \( E_\infty \)-rings play a role in stable homotopy theory analogous to the role played by commutative rings in ordinary algebra. As such, they are the fundamental building blocks of derived algebraic geometry.

One of our ultimate goals in this book is to give an exposition of the theory of \( E_\infty \)-rings. Recall that ordinary commutative ring \( R \) can be viewed as a commutative algebra object in the category of abelian groups, which we view as endowed with a symmetric monoidal structure given by tensor product of abelian groups. To obtain the theory of \( E_\infty \)-rings we will use the same definition, replacing abelian groups by spectra (certain algebro-topological objects which represent cohomology theories). To carry this out in detail, we need to say exactly what a spectrum is. There are many different definitions in the literature, having a
We will take a different approach, using the framework of ∞-categories developed in [97]. The collection of all spectra can be organized into an ∞-category, which we will denote by Sp; it is an ∞-categorical counterpart: the smash product functor on spectra. In order to describe the situation systematically, we introduce the notion of a symmetric monoidal ∞-category: that is, an ∞-category C equipped with a tensor product functor ⊗ : C × C → C which is commutative and associative up to coherent homotopy. For any symmetric monoidal ∞-category C, there is an associated theory of commutative algebra objects, which are themselves organized into an ∞-category CAlg(C). We can then define an E∞-ring to be a commutative algebra object of the ∞-category of spectra, endowed with the symmetric monoidal structure given by smash products.

We now briefly outline the contents of this book (more detailed outlines can be found at the beginning of individual sections and chapters). Much of this book is devoted to developing an adequate language to make sense of the preceding paragraph. We will begin in Chapter 1 by introducing the notion of a stable ∞-category. Roughly speaking, the notion of stable ∞-category is obtained by axiomatizing the essential feature of stable homotopy theory: fiber sequences are the same as cofiber sequences. The ∞-category Sp of spectra is an example of a stable ∞-category. In fact, it is universal among stable ∞-categories: we will show that Sp is freely generated (as a stable ∞-category which admits small colimits) by a single object (see Corollary 1.4.4.6). However, there are a number of stable ∞-categories that are of interest in other contexts. For example, the derived category of an abelian category can be realized as the homotopy category of a stable ∞-category. We may therefore regard the theory of stable ∞-categories as a generalization of homological algebra, which has many applications in pure algebra and algebraic geometry.

We can think of an ∞-category C as comprised of a collection of objects X, Y, Z, . . . ∈ C, together with a mapping space Map_C(X, Y) for every pair of objects X, Y ∈ C (which are equipped with coherently associative composition laws). In Chapter 2, we will study a variation on the notion of ∞-category, which we call an ∞-operad. Roughly speaking, an ∞-operad O consists of a collection of objects together with a space of operations Mul_O({X_1, . . . X_n, Y}) for every finite collection of objects X_1, . . . X_n, Y ∈ O (again equipped with coherently associative multiplication laws). As a special case, we will obtain a theory of symmetric monoidal ∞-categories.

Given a pair of ∞-operads O and C, the collection of maps from O to C is naturally organized into an ∞-category which we will denote by Alg_O(C), and refer to as the ∞-category of O-algebra objects of C. An important special case is when O is the commutative ∞-operad and C is a symmetric monoidal ∞-category: in this case, we will refer to Alg_O(C) as the ∞-category of commutative algebra objects of C and denote it by CAlg(C). We will make a thorough study of algebra objects (commutative and otherwise) in Chapter 3.

In Chapter 4, we will specialize our general theory of algebras to the case where O is the associative ∞-operad. In this case, we will denote Alg_O(C) by Alg(C) and refer to it the ∞-category of associative algebra objects of C. The ∞-categorical theory of associative algebra objects is an excellent formal parallel of the usual theory of associative algebras. For example, one can study left modules, right modules, and bimodules over associative algebras. This theory of modules has some nontrivial applications; for example, in §4.7 we will use it to prove an ∞-categorical analogue of the Barr-Beck theorem, which has many applications in higher category theory.

In ordinary algebra, there is a thin line dividing the theory of commutative rings from the theory of associative rings: a commutative ring R is just an associative ring whose elements satisfy the additional identity xy = yx. In the ∞-categorical setting, the situation is rather different. Between the theory of associative and commutative algebras is a whole hierarchy of intermediate notions of commutativity, which are described by the “little cubes” operads of Boardman and Vogt. In Chapter 5, we will introduce the notion of an E_k-algebra for each 0 ≤ k ≤ ∞. This definition reduces to the notion of an associative algebra in the case k = 1, and to the notion of a commutative algebra when k = ∞. The theory of E_k-algebras has many applications in intermediate cases 1 < k < ∞, and is closely related to the topology of k-dimensional
The theory of differential calculus provides techniques for analyzing a general (smooth) function \( f : \mathbb{R} \to \mathbb{R} \) by studying linear functions which approximate \( f \). A fundamental insight of Goodwillie is that the same ideas can be fruitfully applied to problems in homotopy theory. More precisely, we can sometimes reduce questions about general \( \infty \)-categories and general functors to questions about stable \( \infty \)-categories and exact functors, which are more amenable to attack by algebraic methods. In Chapter 6 we will develop Goodwillie’s calculus of functors in the \( \infty \)-categorical setting. Moreover, we will apply our theory of \( \infty \)-operads to formulate and prove a Koszul dual version of the chain rule of Arone-Ching.

In Chapter 7, we will study \( E_k \)-algebra objects in the symmetric monoidal \( \infty \)-category of spectra, which we refer to as \( E_k \)-rings. This can be regarded as a robust generalization of ordinary noncommutative algebra (when \( k = 1 \)) or commutative algebra (when \( k \geq 2 \)). In particular, we will see that a great deal of classical commutative algebra can be extended to the setting of \( E_\infty \)-rings.

We close the book with two appendices. Appendix A develops the theory of constructible sheaves on stratified topological spaces. Aside from its intrinsic interest, this theory has a close connection with some of the geometric ideas of Chapter 5 and should prove useful in facilitating the application of those ideas. Appendix B is devoted to some rather technical existence results for model category structures on (and Quillen functors between) certain categories of simplicial sets. We recommend that the reader refer to this material only as necessary.

Prerequisites

The following definition will play a central role in this book:

**Definition 0.0.0.1.** An \( \infty \)-category is a simplicial set \( \mathcal{C} \) which satisfies the following extension condition:

\[ (*) \text{ Every map of simplicial sets } f_0 : \Lambda^n_i \to \mathcal{C} \text{ can be extended to an } n \text{-simplex } f : \Delta^n \to \mathcal{C}, \text{ provided that } 0 \leq i < n. \]

**Remark 0.0.0.2.** The notion of \( \infty \)-category was introduced by Boardman and Vogt under the name weak Kan complex in [19]. They have been studied extensively by Joyal, and are often referred to as quasicategories in the literature.

If \( \mathcal{E} \) is a category, then the nerve \( N(\mathcal{E}) \) of \( \mathcal{E} \) is an \( \infty \)-category. Consequently, we can think of the theory of \( \infty \)-categories as a generalization of category theory. It turns out to be a robust generalization: most of the important concepts from classical category theory (limits and colimits, adjoint functors, sheaves and presheaves, etcetera) can be generalized to the setting of \( \infty \)-categories. For a detailed exposition, we refer the reader to our book [97].

**Remark 0.0.0.3.** For a different treatment of the theory of \( \infty \)-categories, we refer the reader to Joyal’s notes [78]. Other references include [19], [82], [79], [80], [115], [39], [40], [121], and [63].

Apart from [97], the formal prerequisites for reading this book are few. We will assume that the reader is familiar with the homotopy theory of simplicial sets (good references on this include [105] and [57]) and with a bit of homological algebra (for which we recommend [160]). Familiarity with other concepts from algebraic topology (spectra, cohomology theories, operads, etcetera) will be helpful, but not strictly necessary: one of the main goals of this book is to give a self-contained exposition of these topics from an \( \infty \)-categorical perspective.

Notation and Terminology

We now call the reader’s attention to some of the terminology used in this book:

- We will make extensive use of definitions and notations from the book [97]. If the reader encounters something confusing or unfamiliar, we recommend looking there first. We adopt the convention that
We say that a category (or ∞-category) $\mathcal{C}$ is presentable if $\mathcal{C}$ admits small colimits and is generated under small colimits by a set of $\kappa$-compact objects, for some regular cardinal number $\kappa$. This is departure from the standard category-theoretic terminology, in which such categories are called locally presentable (see [1]).

We let $\mathbf{Set}_\Delta$ denote the category of simplicial sets. If $J$ is a linearly ordered set, we let $\Delta^J$ denote the simplicial set given by the nerve of $J$, so that the collection of $n$-simplices of $\Delta^J$ can be identified with the collection of all nondecreasing maps $\{0, \ldots, n\} \to J$. We will frequently apply this notation when $J$ is a subset of $\{0, \ldots, n\}$; in this case, we can identify $\Delta^J$ with a subsimplex of the standard $n$-simplex $\Delta^n$ (at least if $J \neq \emptyset$; if $J = \emptyset$, then $\Delta^J$ is empty).

We will often use the term space to refer to a Kan complex (that is, a simplicial set satisfying the Kan extension condition).

Let $n \geq 0$. We will say that a space $X$ is $n$-connective if it is nonempty and the homotopy sets $\pi_i(X, x)$ are trivial for $i < n$ and every vertex $x$ of $X$ (spaces with this property are more commonly referred to as $(n-1)$-connected in the literature). We say that $X$ is connected if it is 1-connective. By convention, we say that every space $X$ is $(−1)$-connective. We will say that a map of spaces $f : X \to Y$ is $n$-connective if the homotopy fibers of $f$ are $n$-connective.

Let $n \geq −1$. We say that a space $X$ is $n$-truncated if the homotopy sets $\pi_i(X, x)$ are trivial for every $i > n$ and every vertex $x \in X$. We say that $X$ is discrete if it is 0-truncated. By convention, we say that $X$ is $(−2)$-truncated if and only if $X$ is contractible. We will say that a map of spaces $f : X \to Y$ is $n$-truncated if the homotopy fibers of $f$ are $n$-truncated.

Throughout this book, we will use homological indexing conventions whenever we discuss homological algebra. For example, chain complexes of abelian groups will be denoted by

$$\cdots \to A_2 \to A_1 \to A_0 \to A_{−1} \to A_{−2} \to \cdots,$$

with the differential lowering the degree by 1.

In Chapter 1, we will construct an ∞-category $Sp$, whose homotopy category $hSp$ can be identified with the classical stable homotopy category. In Chapter 7, we will construct a symmetric monoidal structure on $Sp$, which gives (in particular) a tensor product functor $Sp \times Sp \to Sp$. At the level of the homotopy category $hSp$, this functor is given by the classical smash product of spectra, which is usually denoted by $(X, Y) \mapsto X \wedge Y$. We will adopt a different convention, and denote the smash product functor by $(X, Y) \mapsto X \otimes Y$.

If $\mathcal{A}$ is a model category, we let $\mathcal{A}^v$ denote the full subcategory of $\mathcal{A}$ spanned by the fibrant-cofibrant objects.

Let $\mathcal{E}$ be an ∞-category. We let $\mathcal{E}^{\geq}$ denote the largest Kan complex contained in $\mathcal{E}$: that is, the ∞-category obtained from $\mathcal{E}$ by discarding all noninvertible morphisms.

Let $\mathcal{E}$ be an ∞-category containing objects $X$ and $Y$. We let $\mathcal{E}_{X/}$ and $\mathcal{E}_{/Y}$ denote the undercategory and overcategory defined in §T.1.2.9. We will generally abuse notation by identifying objects of these ∞-categories with their images in $\mathcal{E}$. If we are given a morphism $f : X \to Y$, we can identify $X$ with an object of $\mathcal{E}_{/Y}$ and $Y$ with an object of $\mathcal{E}_{X/}$, so that the ∞-categories

$$(\mathcal{E}_{X/})_{/Y} \quad (\mathcal{E}_{/Y})_{X/}$$

are defined (and canonically isomorphic as simplicial sets). We will denote these ∞-categories by $\mathcal{E}_{X/\backslash Y}$ (beware that this notation is slightly abusive: the definition of $\mathcal{E}_{X/\backslash Y}$ depends not only on $\mathcal{E}$, $X$, and $Y$, but also on the morphism $f$).
• Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories. We let $\text{Fun}^L(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which admit right adjoints, and $\text{Fun}^R(\mathcal{C}, \mathcal{D})$ the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which admit left adjoints. If $\mathcal{C}$ and $\mathcal{D}$ are presentable, then these subcategories admit a simpler characterization: a functor $F : \mathcal{C} \to \mathcal{D}$ belongs to $\text{Fun}^L(\mathcal{C}, \mathcal{D})$ if and only if it preserves small colimits, and belongs to $\text{Fun}^R(\mathcal{C}, \mathcal{D})$ if and only if it preserves small limits and small $\kappa$-filtered colimits for a sufficiently large regular cardinal $\kappa$ (see Corollary T.5.5.2.9).

• We will say that a map of simplicial sets $f : S \to T$ is left cofinal if, for every right fibration $X \to T$, the induced map of simplicial sets $\text{Fun}_T(T, X) \to \text{Fun}_T(S, X)$ is a homotopy equivalence of Kan complexes (in [97], we referred to a map with this property as cofinal). We will say that $f$ is right cofinal if the induced map $S^{\text{op}} \to T^{\text{op}}$ is left cofinal: that is, if $f$ induces a homotopy equivalence $\text{Fun}_T(T, X) \to \text{Fun}_T(S, X)$ for every left fibration $X \to T$. If $S$ and $T$ are $\infty$-categories, then $f$ is left cofinal if and only if for every object $t \in T$, the fiber product $S \times_T T_{t/}$ is weakly contractible (Theorem T.4.1.3.1).

Acknowledgements

In writing this book, I have benefited from the advice and assistance of many people. I would like to thank Ben Antieau, Tobias Barthel, Clark Barwick, Dario Beraldo, Lukas Brantner, Daniel Brügmann, Lee Cohn, Avirup Dutt, Saul Glassman, Moritz Groth, Rune Haugseng, Justin Hilburn, Vladimir Hinich, Allen Knutson, Joseph Lipman, Akhil Mathew, Yogesh More, Anatoly Preygel, Steffen Sagave, Christian Schlichtkrull, Timo Schürg, Elena Sendroiu, Markus Spitzweck, Hiro Tanaka, Arnav Tripathy, and James Wallbridge for locating many mistakes in earlier versions of this book (though I am sure that there are many left to find). I would also like to thank Matt Ando, Clark Barwick, David Ben-Zvi, Alexander Beilinson, Julie Bergner, Andrew Blumberg, Dustin Clausen, Dan Dugger, Vladimir Drinfeld, Matt Emerton, John Francis, Dennis Gaitsgory, Andre Henriques, Gijs Heuts, Mike Hopkins, Andre Joyal, Tyler Lawson, Ieke Moerdijk, David Nadler, Anatoly Preygel, Charles Rezk, David Spivak, Bertrand Toën, and Gabriele Vezzosi for useful conversations related to the subject matter of this book. Finally, I would like to thank the National Science Foundation for supporting this project under grant number 0906194.
Chapter 1

Stable \(\infty\)-Categories

There is a very useful analogy between topological spaces and chain complexes with values in an abelian category. For example, it is customary to speak of homotopies between chain maps, contractible complexes, and so forth. The analogue of the homotopy category of topological spaces is the derived category of an abelian category \(\mathcal{A}\), a triangulated category which provides a good setting for many constructions in homological algebra. However, it has long been recognized that for many purposes the derived category is too crude: it identifies homotopic morphisms of chain complexes without remembering why they are homotopic. It is possible to correct this defect by viewing the derived category as the homotopy category of an underlying \(\infty\)-category \(\mathcal{D}(\mathcal{A})\). The \(\infty\)-categories which arise in this way have special features that reflect their “additive” origins: they are stable.

We will begin in §1.1 by giving the definition of stability and exploring some of its consequences. For example, we will show that if \(\mathcal{C}\) is a stable \(\infty\)-category, then its homotopy category \(h\mathcal{C}\) is triangulated (Theorem 1.1.2.15), and that stable \(\infty\)-categories admit finite limits and colimits (Proposition 1.1.3.4). The appropriate notion of functor between stable \(\infty\)-categories is an exact functor: that is, a functor which preserves finite colimits (or equivalently, finite limits: see Proposition 1.1.4.1). The collection of stable \(\infty\)-categories and exact functors between them can be organized into an \(\infty\)-category, which we will denote by \(\mathcal{C}at^{\text{Ex}}_{\infty}\). In §1.1.4, we will establish some basic closure properties of the \(\infty\)-category \(\mathcal{C}at^{\text{Ex}}_{\infty}\); in particular, we will show that it is closed under the formation of limits and filtered colimits in \(\mathcal{C}at_{\infty}\). The formation of limits in \(\mathcal{C}at^{\text{Ex}}_{\infty}\) provides a tool for addressing the classical problem of “gluing in the derived category”.

In §1.2, we recall the definition of a t-structure on a triangulated category. If \(\mathcal{C}\) is a stable \(\infty\)-category, we define a t-structure on \(\mathcal{C}\) to be a t-structure on its homotopy category \(h\mathcal{C}\). If \(\mathcal{C}\) is equipped with a t-structure, we show that every filtered object of \(\mathcal{C}\) gives rise to a spectral sequence taking values in the heart \(\mathcal{C}^{\text{h}}\) (Proposition 1.2.2.7). In particular, we show that every simplicial object of \(\mathcal{C}\) determines a spectral sequence, using an \(\infty\)-categorical analogue of the Dold-Kan correspondence.

We will return to the setting of homological algebra in §1.3. To any abelian category \(\mathcal{A}\) with enough projective objects, one can associate a stable \(\infty\)-category \(\mathcal{D}^{-}(\mathcal{A})\), whose objects are (right-bounded) chain complexes of projective objects of \(\mathcal{A}\). This \(\infty\)-category provides useful tools for organizing information in homological algebra. Our main result (Theorem 1.3.3.8) is a characterization of \(\mathcal{D}^{-}(\mathcal{A})\) by a universal mapping property.

In §1.4, we will focus our attention on a particular stable \(\infty\)-category: the \(\infty\)-category \(\mathcal{S}p\) of spectra. The homotopy category of \(\mathcal{S}p\) can be identified with the classical stable homotopy category, which is the natural setting for a large portion of modern algebraic topology. Roughly speaking, a spectrum is a sequence of pointed spaces \(\{X(n)\}_{n \in \mathbb{Z}}\) equipped with homotopy equivalences \(X(n) \simeq \Omega X(n + 1)\), where \(\Omega\) denotes the functor given by passage to the loop space. More generally, one can obtain a stable \(\infty\)-category by considering sequences as above which take values in an arbitrary \(\infty\)-category \(\mathcal{C}\) which admits finite limits; we denote this \(\infty\)-category by \(\mathcal{S}p(\mathcal{C})\) and refer to it as the \(\infty\)-category of spectrum objects of \(\mathcal{C}\).
CHAPTER 1. STABLE ∞-CATEGORIES

1.1 Foundations

Our goal in this section is to introduce our main object of study for this chapter: the notion of a stable ∞-category. The theory of stable ∞-categories can be regarded as an axiomatization of the essential features of stable homotopy theory: most notably, that fiber sequences and cofiber sequences are the same. We will begin in §1.1.1 by reviewing some of the relevant notions (pointed ∞-categories, zero objects, fiber and cofiber sequences) and using them to define the class of stable ∞-categories.

In §1.1.2, we will review Verdier’s definition of a triangulated category. We will show that if ℂ is a stable ∞-category, then its homotopy category ℉ℂ has the structure of a triangulated category (Theorem 1.1.2.15). The theory of triangulated categories can be regarded as an attempt to capture those features of stable ∞-categories which are easily visible at the level of homotopy categories. Triangulated categories which arise naturally in mathematics are usually given as the homotopy categories of stable ∞-categories, though it is possible to construct triangulated categories which are not of this form (see [113]).

Our next goal is to study the properties of stable ∞-categories in greater depth. In §1.1.3, we will show that a stable ∞-category ℂ admits all finite limits and colimits, and that pullback squares and pushout squares in ℂ are the same (Proposition 1.1.3.4). We will also show that the class of stable ∞-categories is closed under various natural operations. For example, we will show that if ℂ is a stable ∞-category, then the ∞-category of Ind-objects Ind(ℂ) is stable (Proposition 1.1.3.6), and that the ∞-category of diagrams Fun(K, ℂ) is stable for any simplicial set K (Proposition 1.1.3.1).

In §1.1.4, we shift our focus somewhat. Rather than concerning ourselves with the properties of an individual stable ∞-category ℂ, we will study the collection of all stable ∞-categories. To this end, we introduce the notion of an exact functor between stable ∞-categories. We will show that the collection of all (small) stable ∞-categories and exact functors between them can itself be organized into an ∞-category Cat∞Ex, and study some of the properties of Cat∞Ex.

Remark 1.1.0.1. The theory of stable ∞-categories is not really new: most of the results presented here are well-known to experts. There exists a growing literature on the subject in the setting of stable model categories: see, for example, [37], [126], [128], and [72]. For a brief account in the more flexible setting of Segal categories, we refer the reader to [153].

Remark 1.1.0.2. Let ℂ be a field. Recall that a differential graded category over ℂ is a category enriched over the category of chain complexes of ℂ-vector spaces. The theory of differential graded categories is closely related to the theory of stable ∞-categories. More precisely, one can show that the data of a (pretriangulated) differential graded category over ℂ is equivalent to the data of a stable ∞-category ℂ equipped with an enrichment over the monoidal ∞-category of ℂ-module spectra. The theory of differential graded categories provides a convenient language for working with stable ∞-categories of algebraic origin (for example, those which arise from chain complexes of coherent sheaves on algebraic varieties), but is inadequate for treating examples which arise in stable homotopy theory. There is a voluminous literature on the subject; see, for example, [84], [101], [141], [35], and [147].

1.1.1 Stability

In this section, we introduce the definition of a stable ∞-category. We begin by reviewing some definitions from [97].

Definition 1.1.1.1. Let ℂ be an ∞-category. A zero object of ℂ is an object which is both initial and final. We will say that ℂ is pointed if it contains a zero object.

In other words, an object 0 ∈ ℂ is zero if the spaces Mapₐ(X, 0) and Mapₐ(0, X) are both contractible for every object X ∈ ℂ. Note that if ℂ contains a zero object, then that object is determined up to equivalence. More precisely, the full subcategory of ℂ spanned by the zero objects is a contractible Kan complex (Proposition T.1.2.12.9).
Remark 1.1.2. Let \( \mathcal{C} \) be an \( \infty \)-category. Then \( \mathcal{C} \) is pointed if and only if the following conditions are satisfied:

1. The \( \infty \)-category \( \mathcal{C} \) has an initial object \( \emptyset \).
2. The \( \infty \)-category \( \mathcal{C} \) has a final object 1.
3. There exists a morphism \( f : 1 \to \emptyset \) in \( \mathcal{C} \).

The “only if” direction is obvious. For the converse, let us suppose that (1), (2), and (3) are satisfied. We invoke the assumption that \( \emptyset \) is initial to deduce the existence of a morphism \( g : \emptyset \to 1 \). Because \( \emptyset \) is initial, \( f \circ g \simeq \text{id}_\emptyset \), and because 1 is final, \( g \circ f \simeq \text{id}_1 \). Thus \( g \) is a homotopy inverse to \( f \), so that \( f \) is an equivalence. It follows that \( \emptyset \) is also a final object of \( \mathcal{C} \), so that \( \mathcal{C} \) is pointed.

Remark 1.1.3. Let \( \mathcal{C} \) be an \( \infty \)-category with a zero object 0. For any \( X, Y \in \mathcal{C} \), the natural map

\[
\text{Map}_\mathcal{C}(X, 0) \times \text{Map}_\mathcal{C}(0, Y) \to \text{Map}_\mathcal{C}(X, Y)
\]

has contractible domain. We therefore obtain a well defined morphism \( X \to Y \) in the homotopy category \( \mathcal{hC} \), which we will refer to as the zero morphism and also denote by 0.

Definition 1.1.4. Let \( \mathcal{C} \) be a pointed \( \infty \)-category. A triangle in \( \mathcal{C} \) is a diagram \( \Delta^1 \times \Delta^1 \to \mathcal{C} \), depicted as

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow & & \downarrow \\
0 & \xrightarrow{g} & Z
\end{array}
\]

where 0 is a zero object of \( \mathcal{C} \). We will say that a triangle in \( \mathcal{C} \) is a fiber sequence if it is a pullback square, and a cofiber sequence if it is a pushout square.

Remark 1.1.5. Let \( \mathcal{C} \) be a pointed \( \infty \)-category. A triangle in \( \mathcal{C} \) consists of the following data:

1. A pair of morphisms \( f : X \to Y \) and \( g : Y \to Z \) in \( \mathcal{C} \).
2. A 2-simplex in \( \mathcal{C} \) corresponding to a diagram

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
X & \xrightarrow{h} & Z
\end{array}
\]

in \( \mathcal{C} \), which identifies \( h \) with the composition \( g \circ f \).

3. A 2-simplex

\[
\begin{array}{ccc}
X & \xrightarrow{h} & Z \\
\downarrow & & \downarrow \\
0 & \xrightarrow{} & Z
\end{array}
\]

in \( \mathcal{C} \), which we may view as a nullhomotopy of \( h \).

We will generally indicate a triangle by specifying only the pair of maps

\[
X \xrightarrow{f} Y \xrightarrow{g} Z,
\]

with the data of (2) and (3) being implicitly assumed.
**Definition 1.1.1.6.** Let \( C \) be a pointed \( \infty \)-category containing a morphism \( g : X \to Y \). A **fiber** of \( g \) is a fiber sequence

\[
\begin{array}{c}
W \\
\downarrow \\
0
\end{array} 
\xrightarrow{g} 
\begin{array}{c}
X \\
\downarrow \\
0
\end{array} 
\xrightarrow{g} 
\begin{array}{c}
Y \\
\downarrow \\
0
\end{array}
\]

Dually, a **cofiber** of \( g \) is a cofiber sequence

\[
\begin{array}{c}
X \\
\downarrow \\
0
\end{array} 
\xleftarrow{g} 
\begin{array}{c}
Y \\
\downarrow \\
0
\end{array} 
\xleftarrow{g} 
\begin{array}{c}
Z \\
\downarrow \\
0
\end{array}
\]

We will generally abuse terminology by simply referring to \( W \) and \( Z \) as the fiber and cofiber of \( g \). We will also write \( W = \text{fib}(g) \) and \( Z = \text{cofib}(g) \).

**Remark 1.1.1.7.** Let \( C \) be a pointed \( \infty \)-category containing a morphism \( f : X \to Y \). A cofiber of \( f \), if it exists, is uniquely determined up to equivalence. More precisely, consider the full subcategory \( \mathcal{E} \subseteq \text{Fun}(\Delta^1 \times \Delta^1, C) \) spanned by the cofiber sequences. Let \( \theta : \mathcal{E} \to \text{Fun}(\Delta^1, C) \) be the forgetful functor, which associates to a diagram

\[
\begin{array}{c}
X \\
\downarrow \\
0
\end{array} 
\xleftarrow{g} 
\begin{array}{c}
Y \\
\downarrow \\
0
\end{array}
\]

the morphism \( g : X \to Y \). Applying Proposition T.4.3.2.15 twice, we deduce that \( \theta \) is a Kan fibration, whose fibers are either empty or contractible (depending on whether or not a morphism \( g : X \to Y \) in \( C \) admits a cofiber). In particular, if every morphism in \( \mathcal{E} \) admits a cofiber, then \( \theta \) is a trivial Kan fibration, and therefore admits a section \( \text{cofib} : \text{Fun}(\Delta^1, \mathcal{E}) \to \text{Fun}(\Delta^1 \times \Delta^1, \mathcal{E}) \), which is well defined up to a contractible space of choices. We will often abuse notation by also letting \( \text{cofib} : \text{Fun}(\Delta^1, \mathcal{E}) \to \mathcal{E} \) denote the composition

\[
\text{Fun}(\Delta^1, \mathcal{E}) \to \text{Fun}(\Delta^1 \times \Delta^1, \mathcal{E}) \to \mathcal{E},
\]

where the second map is given by evaluation at the final object of \( \Delta^1 \times \Delta^1 \).

**Remark 1.1.1.8.** The functor \( \text{cofib} : \text{Fun}(\Delta^1, \mathcal{E}) \to \mathcal{E} \) can be identified with a left adjoint to the left Kan extension functor \( \mathcal{E} \simeq \text{Fun}(\{1\}, \mathcal{E}) \to \text{Fun}(\Delta^1, \mathcal{E}) \), which associates to each object \( X \in \mathcal{E} \) a zero morphism \( 0 \to X \). It follows that \( \text{cofib} \) preserves all colimits which exist in \( \text{Fun}(\Delta^1, \mathcal{E}) \) (Proposition T.5.2.3.5).

**Definition 1.1.1.9.** An \( \infty \)-category \( \mathcal{C} \) is **stable** if it satisfies the following conditions:

1. There exists a zero object \( 0 \in \mathcal{C} \).
2. Every morphism in \( \mathcal{C} \) admits a fiber and a cofiber.
3. A triangle in \( \mathcal{C} \) is a fiber sequence if and only if it a cofiber sequence.

**Remark 1.1.1.10.** Condition (3) of Definition 1.1.1.9 is analogous to the axiom for abelian categories which requires that the image of a morphism be isomorphic to its coimage.

**Example 1.1.1.11.** Recall that a **spectrum** consists of an infinite sequence of pointed topological spaces \( \{X_i\}_{i \geq 0} \), together with homeomorphisms \( X_i \simeq \Omega X_{i+1} \), where \( \Omega \) denotes the loop space functor. The collection of spectra can be organized into a stable \( \infty \)-category \( \text{Sp} \). Moreover, \( \text{Sp} \) is in some sense the universal example of a stable \( \infty \)-category. This motivates the terminology of Definition 1.1.1.9: an \( \infty \)-category \( \mathcal{C} \) is stable if it resembles the \( \infty \)-category \( \text{Sp} \), whose homotopy category \( h\text{Sp} \) can be identified with the classical **stable homotopy category**. We will return to the theory of spectra (using a slightly different definition) in §1.4.3.
Example 1.1.1.12. Let $\mathcal{A}$ be an abelian category. Under mild hypotheses, we can construct a stable $\infty$-category $\mathcal{D}(\mathcal{A})$ whose homotopy category $\text{hD}(\mathcal{A})$ can be identified with the derived category of $\mathcal{A}$, in the sense of classical homological algebra. We will outline the construction of $\mathcal{D}(\mathcal{A})$ in §1.3.2.

Remark 1.1.1.13. If $\mathcal{C}$ is a stable $\infty$-category, then the opposite $\infty$-category $\mathcal{C}^{\text{op}}$ is also stable.

Remark 1.1.1.14. One attractive feature of the theory of stable $\infty$-categories is that stability is a property of $\infty$-categories, rather than additional data. The situation for additive categories is similar. Although additive categories are often presented as categories equipped with additional structure (an abelian group structure on all Hom-sets), this additional structure is in fact determined by the underlying category: see Definition 1.1.2.1. The situation for stable $\infty$-categories is similar: we will see later that every stable $\infty$-category is canonically enriched over the $\infty$-category of spectra.

1.1.2 The Homotopy Category of a Stable $\infty$-Category

Let $M$ be a module over a commutative ring $R$. Then $M$ admits a resolution

$$\cdots \to P_2 \to P_1 \to P_0 \to M \to 0$$

by projective $R$-modules. In fact, there are generally many choices for such a resolution. Two projective resolutions of $M$ need not be isomorphic to one another. However, they are always quasi-isomorphic: that is, if we are given two projective resolutions $P_\bullet$ and $P'_\bullet$ of $M$, then there is a map of chain complexes $P_\bullet \to P'_\bullet$ which induces an isomorphism on homology groups. This phenomenon is ubiquitous in homological algebra: many constructions produce chain complexes which are not really well-defined up to isomorphism, but only up to quasi-isomorphism. In studying these constructions, it is often convenient to work in the derived category $\mathcal{D}(R)$ of the ring $R$: that is, the category obtained from the category of chain complexes of $R$-modules by formally inverting all quasi-isomorphisms.

The derived category $\mathcal{D}(R)$ of a commutative ring $R$ is usually not an abelian category. For example, a morphism $f: X' \to X$ in $\mathcal{D}(R)$ usually does not have a cokernel in $\mathcal{D}(R)$. Instead, one can associate to $f$ its cofiber (or mapping cone) $X''$, which is well-defined up to noncanonical isomorphism. In [155], Verdier introduced the notion of a triangulated category in order to axiomatize the structure on $\mathcal{D}(R)$ given by the formation of mapping cones. In this section, we will review Verdier’s theory of triangulated categories (Definition 1.1.2.6) and show that the homotopy category of a stable $\infty$-category $\mathcal{C}$ is triangulated (Theorem 1.1.2.15).

We begin with some basic definitions.

Definition 1.1.2.1. Let $\mathcal{A}$ be a category. We will say that $\mathcal{A}$ is additive if it satisfies the following four conditions:

1. The category $\mathcal{A}$ admits finite products and coproducts.
2. The category $\mathcal{A}$ has a zero object, which we will denote by 0.
3. For any pair of objects $X, Y \in \mathcal{A}$, a zero morphism from $X$ to $Y$ is a map $f: X \to Y$ which factors as a composition $X \to 0 \to Y$. It follows from (2) that for every pair $X, Y \in \mathcal{A}$, there is a unique zero morphism from $X$ to $Y$, which we will denote by 0.
4. For every pair of objects $X, Y$, the map $X \coprod Y \to X \times Y$ described by the matrix

$$\begin{bmatrix} \text{id}_X & 0 \\ 0 & \text{id}_Y \end{bmatrix}$$

is an isomorphism; let $\phi_{X,Y}$ denote its inverse.
Assuming (3), we can define the sum of two morphisms $f, g : X \to Y$ to be the morphism $f + g$ given by the composition

$$X \to X \times X \xrightarrow{f \times g} Y \times Y \xrightarrow{\phi_{Y,Y}} Y \coprod Y \to Y.$$ 

It is easy to see that this construction endows $\text{Hom}_A(X, Y)$ with the structure of a commutative monoid, whose identity is the unique zero morphism from $X$ to $Y$.

(4) For every pair of objects $X, Y \in A$, the addition defined above determines a group structure on $\text{Hom}_A(X, Y)$. In other words, for every morphism $f : X \to Y$, there exists another morphism $-f : X \to Y$ such that $f + (-f)$ is a zero morphism from $X$ to $Y$.

**Remark 1.1.2.2.** An additive category $A$ is said to be abelian if every morphism $f : X \to Y$ in $A$ admits a kernel and a cokernel, and the canonical map $\text{coker}(\ker(f) \to X) \to \ker(Y \to \text{coker}(f))$ is an isomorphism.

**Remark 1.1.2.3.** In §??, we will study an $\infty$-categorical generalization of Definition 1.1.2.1.

**Remark 1.1.2.4.** Let $A$ be an additive category. Then the composition law on $A$ is bilinear: for pairs of morphisms $f, f' \in \text{Hom}_A(X, Y)$ and $g, g' \in \text{Hom}_A(Y, Z)$, we have

$$g \circ (f + f') = (g \circ f) + (g \circ f') \quad (g + g') \circ f = (g \circ f) + (g' \circ f).$$

In other words, the composition law on $A$ determines abelian group homomorphisms

$$\text{Hom}_A(X, Y) \otimes \text{Hom}_A(Y, Z) \to \text{Hom}_A(X, Z).$$

We can summarize the situation by saying that the category $A$ is enriched over the category of abelian groups.

**Remark 1.1.2.5.** Let $A$ be an additive category. It follows from condition (3) of Definition 1.1.2.1 that for every pair of objects $X, Y \in A$, the product $X \times Y$ is canonically isomorphic to the coproduct $X \coprod Y$. It is customary to emphasize this identification by denoting both the product and the coproduct by $X \oplus Y$; we will refer to $X \oplus Y$ as the direct sum of $X$ and $Y$.

**Definition 1.1.2.6 (Verdier).** A triangulated category consists of the following data:

(1) An additive category $\mathcal{D}$.

(2) A translation functor $\mathcal{D} \to \mathcal{D}$ which is an equivalence of categories. We denote this functor by $X \mapsto X[1]$.

(3) A collection of distinguished triangles

$$X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1].$$

These data are required to satisfy the following axioms:

\begin{itemize}
  \item[(TR1)] (a) Every morphism $f : X \to Y$ in $\mathcal{D}$ can be extended to a distinguished triangle in $\mathcal{D}$.
  \item[(b)] The collection of distinguished triangles is stable under isomorphism.
  \item[(c)] Given an object $X \in \mathcal{D}$, the diagram

$$X \xrightarrow{\text{id}_X} X \to 0 \to X[1]$$

is a distinguished triangle.
1.1. FOUNDATIONS

(TR2) A diagram

\[
X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]
\]

is a distinguished triangle if and only if the rotated diagram

\[
Y \xrightarrow{g} Z \xrightarrow{h} X[1] \xrightarrow{-f[1]} Y[1]
\]

is a distinguished triangle.

(TR3) Given a commutative diagram

\[
\begin{array}{ccc}
X & \rightarrow & Y & \rightarrow & Z & \rightarrow & X[1] \\
\downarrow f & & \downarrow & & \downarrow f[1] & & \\
X' & \rightarrow & Y' & \rightarrow & Z' & \rightarrow & X'[1]
\end{array}
\]

in which both horizontal rows are distinguished triangles, there exists a dotted arrow rendering the entire diagram commutative.

(TR4) Suppose given three distinguished triangles

\[
\begin{align*}
X & \xrightarrow{f} Y \xrightarrow{u} Y/X \xrightarrow{d} X[1] \\
Y & \xrightarrow{g} Z \xrightarrow{v} Z/Y \xrightarrow{d'} Y[1] \\
X & \xrightarrow{gof} Z \xrightarrow{w} Z/X \xrightarrow{d''} X[1]
\end{align*}
\]

in \( \mathcal{D} \). There exists a fourth distinguished triangle

\[
Y/X \xrightarrow{\phi} Z/X \xrightarrow{\psi} Z/Y \xrightarrow{\theta} Y/X[1]
\]

such that the diagram

\[
\begin{array}{ccc}
X & \xrightarrow{gof} & Z & \xrightarrow{v} & Z/Y & \xrightarrow{\theta} & Y/X[1] \\
\downarrow f & & \downarrow g & & \downarrow \psi & & \downarrow \theta \\
Y & \xrightarrow{u} & Z/X & \xrightarrow{\phi} & Y/X & \xrightarrow{d} & X[1] \\
\downarrow u[1] & & \downarrow d' & & \downarrow f[1] & & \\
Y/X & \xrightarrow{d''} & X[1]
\end{array}
\]

commutes.

We now consider the problem of constructing a triangulated structure on the homotopy category of an \( \infty \)-category \( \mathcal{C} \). Let us begin by assuming only that \( \mathcal{C} \) is a pointed \( \infty \)-category. We let \( \mathcal{X}^{\mathcal{C}} \) denote the full subcategory of \( \text{Fun}(\Delta^1 \times \Delta^1, \mathcal{C}) \) spanned by those diagrams

\[
\begin{array}{ccc}
X & \rightarrow & 0 \\
\downarrow & & \downarrow \\
0' & \rightarrow & Y
\end{array}
\]
which are pushout squares, and such that 0 and 0' are zero objects of \( \mathcal{C} \). If \( \mathcal{C} \) admits cofibers, then we can use Proposition T.4.3.2.15 (twice) to conclude that evaluation at the initial vertex induces a trivial fibration \( M^2 \to \mathcal{C} \). Let \( s : \mathcal{C} \to M^2 \) be a section of this trivial fibration, and let \( e : M^2 \to \mathcal{C} \) be the functor given by evaluation at the final vertex. The composition \( e \circ s \) is a functor from \( \mathcal{C} \) to itself, which we will denote by \( \Sigma : \mathcal{C} \to \mathcal{C} \) and refer to as the suspension functor on \( \mathcal{C} \). Dually, we define \( M^\Omega \) to be the full subcategory of \( \text{Fun}(\Delta^1 \times \Delta^1, \mathcal{C}) \) spanned by diagrams as above which are pullback squares with 0 and 0' zero objects of \( \mathcal{C} \). If \( \mathcal{C} \) admits fibers, then the same argument shows that evaluation at the final vertex induces a trivial fibration \( \mathcal{M}^\Omega \to \mathcal{C} \). If we let \( s' \) denote a section to this trivial fibration, then the composition of \( s' \) with evaluation at the initial vertex induces a functor from \( \mathcal{C} \) to itself, which we will refer to as the loop functor and denote by \( \Omega : \mathcal{C} \to \mathcal{C} \). If \( \mathcal{C} \) is stable, then \( M^\Omega = M^2 \). It follows that \( \Sigma \) and \( \Omega \) are mutually inverse equivalences from \( \mathcal{C} \) to itself.

**Remark 1.1.2.7.** If the \( \infty \)-category \( \mathcal{C} \) is not clear from context, then we will denote the suspension and loop functors \( \Sigma, \Omega : \mathcal{C} \to \mathcal{C} \) by \( \Sigma_\mathcal{C} \) and \( \Omega_\mathcal{C} \), respectively.

**Notation 1.1.2.8.** If \( \mathcal{C} \) is a stable \( \infty \)-category and \( n \geq 0 \), we let

\[
X \mapsto X[n]
\]

denote the \( n \)th power of the suspension functor \( \Sigma : \mathcal{C} \to \mathcal{C} \) constructed above (this functor is well-defined up to canonical equivalence). If \( n \leq 0 \), we let \( X \mapsto X[n] \) denote the \((-n)\)th power of the loop functor \( \Omega \). We will use the same notation to indicate the induced functors on the homotopy category \( h\mathcal{C} \).

**Remark 1.1.2.9.** If the \( \infty \)-category \( \mathcal{C} \) is pointed but not necessarily stable, the suspension and loop space functors need not be homotopy inverses but are nevertheless adjoint to one another (provided that both functors are defined).

If \( \mathcal{C} \) is a pointed \( \infty \)-category containing a pair of objects \( X \) and \( Y \), then the space \( \text{Map}_\mathcal{C}(X,Y) \) has a natural base point, given by the zero map. Moreover, if \( \mathcal{C} \) admits cofibers, then the suspension functor \( \Sigma_\mathcal{C} : \mathcal{C} \to \mathcal{C} \) is essentially characterized by the existence of natural homotopy equivalences

\[
\text{Map}_\mathcal{C}(\Sigma(X),Y) \to \Omega \text{Map}_\mathcal{C}(X,Y).
\]

In particular, we conclude that \( \pi_0 \text{Map}_\mathcal{C}(\Sigma(X),Y) \simeq \pi_1 \text{Map}_\mathcal{C}(X,Y) \), so that \( \pi_0 \text{Map}_\mathcal{C}(\Sigma(X),Y) \) has the structure of a group (here the fundamental group of \( \text{Map}_\mathcal{C}(X,Y) \) is taken with base point given by the zero map). Similarly, \( \pi_0 \text{Map}_\mathcal{C}(\Sigma^2(X),Y) \simeq \pi_2 \text{Map}_\mathcal{C}(X,Y) \) has the structure of an abelian group. If the suspension functor \( X \mapsto \Sigma(X) \) is an equivalence of \( \infty \)-categories, then for every \( Z \in \mathcal{C} \) we can choose \( X \) such that \( \Sigma^2(X) \simeq Z \) to deduce the existence of an abelian group structure on \( \text{Map}_\mathcal{C}(Z,Y) \). It is easy to see that this group structure depends functorially on \( Z,Y \in h\mathcal{C} \). We are therefore most of the way to proving the following result:

**Lemma 1.1.2.10.** Let \( \mathcal{C} \) be a pointed \( \infty \)-category which admits cofibers, and suppose that the suspension functor \( \Sigma : \mathcal{C} \to \mathcal{C} \) is an equivalence. Then \( h\mathcal{C} \) is an additive category.

**Proof.** The argument sketched above shows that \( h\mathcal{C} \) is (canonically) enriched over the category of abelian groups. It will therefore suffice to prove that \( h\mathcal{C} \) admits finite coproducts. We will prove a slightly stronger statement: the \( \infty \)-category \( \mathcal{C} \) itself admits finite coproducts. Since \( \mathcal{C} \) has an initial object, it will suffice to treat the case of pairwise coproducts. Let \( X,Y \in \mathcal{C} \), and let \( \text{cofib} : \text{Fun}(\Delta^1, \mathcal{C}) \to \mathcal{C} \) denote the functor which assign to each morphism its cofiber, so that we have equivalences \( X \simeq \text{cofib}(X[-1] \xrightarrow{=} 0) \) and \( Y \simeq \text{cofib}(0 \xrightarrow{=} Y) \). Proposition T.5.1.2.2 implies that \( u \) and \( v \) admit a coproduct in \( \text{Fun}(\Delta^1, \mathcal{C}) \) (namely, the zero map \( X[-1] \xrightarrow{0} Y \)). Since the functor \( \text{cofib} \) preserves coproducts (Remark 1.1.1.8), we conclude that \( X \) and \( Y \) admit a coproduct (which can be constructed as the cofiber of the zero map from \( X[-1] \) to \( Y \)).
Let $\mathcal{C}$ be a pointed $\infty$-category which admits cofibers. By construction, any diagram
\[
\begin{array}{ccc}
X & \rightarrow & 0 \\
\downarrow & & \downarrow \\
0' & \rightarrow & Y
\end{array}
\]
which belongs to $\mathcal{M}^{\Sigma}$ determines a canonical isomorphism $X[1] \rightarrow Y$ in the homotopy category $\text{h}\mathcal{C}$. We will need the following observation:

**Lemma 1.1.2.11.** Let $\mathcal{C}$ be a pointed $\infty$-category which admits cofibers, and let
\[
\begin{array}{ccc}
X & \xrightarrow{f} & 0 \\
\downarrow & & \downarrow \\
0' & \rightarrow & Y
\end{array}
\]
be a diagram in $\mathcal{C}$, classifying a morphism $\theta \in \text{Hom}_{\text{h}\mathcal{C}}(X[1], Y)$. (Here $0$ and $0'$ are zero objects of $\mathcal{C}$.) Then the transposed diagram
\[
\begin{array}{ccc}
X & \xrightarrow{f'} & 0' \\
\downarrow & & \downarrow \\
0 & \rightarrow & Y
\end{array}
\]
classifies the morphism $-\theta \in \text{Hom}_{\text{h}\mathcal{C}}(X[1], Y)$. Here $-\theta$ denotes the inverse of $\theta$ with respect to the group structure on $\text{Hom}_{\text{h}\mathcal{C}}(X[1], Y) \simeq \pi_1 \text{Map}_{\mathcal{C}}(X, Y)$.

**Proof.** Without loss of generality, we may suppose that $0 = 0'$ and $f = f'$. Let $\sigma : \Lambda^2_0 \rightarrow \mathcal{C}$ be the diagram
\[
0 \leftarrow X \xrightarrow{f} 0.
\]
For every diagram $p : K \rightarrow \mathcal{C}$, let $\mathcal{D}(p)$ denote the Kan complex $\mathcal{C}_p \times_{\mathcal{C}} \{Y\}$. Then $\text{Hom}_{\text{h}\mathcal{C}}(X[1], Y) \simeq \pi_0 \mathcal{D}(\sigma)$. We note that
\[
\mathcal{D}(\sigma) \simeq \mathcal{D}(f) \times_{\mathcal{D}(X)} \mathcal{D}(f).
\]
Since $0$ is an initial object of $\mathcal{C}$, $\mathcal{D}(f)$ is contractible. In particular, there exists a point $q \in \mathcal{D}(f)$. Let
\[
\mathcal{D}' = \mathcal{D}(f) \times_{\text{Fun}(\{0\}, \mathcal{D}(X))} \text{Fun}(\Delta^1, \mathcal{D}(X)) \times_{\text{Fun}(\{1\}, \mathcal{D}(X))} \mathcal{D}(f)
\]
\[
\mathcal{D}'' = \{q\} \times_{\text{Fun}(\{0\}, \mathcal{D}(X))} \text{Fun}(\Delta^1, \mathcal{D}(X)) \times_{\text{Fun}(\{1\}, \mathcal{D}(X))} \{q\}
\]
so that we have canonical inclusions
\[
\mathcal{D}'' \hookrightarrow \mathcal{D}' \hookrightarrow \mathcal{D}(\sigma).
\]
The left map is a homotopy equivalence because $\mathcal{D}(f)$ is contractible, and the right map is a homotopy equivalence because the projection $\mathcal{D}(f) \rightarrow \mathcal{D}(X)$ is a Kan fibration. We observe that $\mathcal{D}''$ can be identified with the simplicial loop space of $\text{Hom}_{\mathcal{C}}(X, Y)$ (taken with the base point determined by $q$, which we can identify with the zero map from $X$ to $Y$). Each of the Kan complexes $\mathcal{D}(\sigma)$, $\mathcal{D}'$, $\mathcal{D}''$ is equipped with a canonical involution. On $\mathcal{D}(\sigma)$, this involution corresponds to the transposition of diagrams as in the statement of the lemma. On $\mathcal{D}'$, this involution corresponds to reversal of loops. The desired conclusion now follows from the observation that these involutions are compatible with the inclusions $\mathcal{D}'' \subset \mathcal{D}'$. \qed
CHAPTER 1. STABLE ∞-CATEGORIES

Definition 1.1.2.12. Let \( \mathcal{C} \) be a pointed ∞-category which admits cofibers. Suppose given a diagram

\[
X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]
\]

in the homotopy category \( h\mathcal{C} \). We will say that this diagram is a distinguished triangle if there exists a diagram \( \Delta^1 \times \Delta^2 \to \mathcal{C} \) as shown

\[
\begin{array}{ccc}
X & \xrightarrow{\bar{f}} & Y \\
\downarrow & & \downarrow \\
0' & \xrightarrow{\bar{g}} & Z \\
\downarrow & & \downarrow \\
0' & \xrightarrow{\bar{h}} & W,
\end{array}
\]

satisfying the following conditions:

(i) The objects \( 0, 0' \in \mathcal{C} \) are zero.

(ii) Both squares are pushout diagrams in \( \mathcal{C} \).

(iii) The morphisms \( \bar{f} \) and \( \bar{g} \) represent \( f \) and \( g \), respectively.

(iv) The map \( h : Z \to X[1] \) is the composition of (the homotopy class of) \( \bar{h} \) with the equivalence \( W \simeq X[1] \) determined by the outer rectangle.

Remark 1.1.2.13. We will generally only use Definition 1.1.2.12 in the case where \( \mathcal{C} \) is a stable ∞-category. However, it will be convenient to have the terminology available in the case where \( \mathcal{C} \) is not yet known to be stable.

The following result is an immediate consequence of Lemma 1.1.2.11:

Lemma 1.1.2.14. Let \( \mathcal{C} \) be a stable ∞-category. Suppose given a diagram \( \Delta^2 \times \Delta^1 \to \mathcal{C} \), depicted as

\[
\begin{array}{ccc}
X & \xrightarrow{f} & 0 \\
\downarrow & & \downarrow \\
Y & \xrightarrow{g} & Z \\
\downarrow & & \downarrow \\
0' & \xrightarrow{h} & W,
\end{array}
\]

where both squares are pushouts and the objects \( 0, 0' \in \mathcal{C} \) are zero. Then the diagram

\[
X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{-h'} X[1]
\]

is a distinguished triangle in \( h\mathcal{C} \), where \( h' \) denotes the composition of \( h \) with the isomorphism \( W \simeq X[1] \) determined by the outer square, and \(-h'\) denotes the composition of \( h' \) with the map \(-\text{id} \in \text{Hom}_{h\mathcal{C}}(X[1], X[1]) \simeq \pi_1 \text{Map}_{h\mathcal{C}}(X, X[1])\).

We can now state the main result of this section:

Theorem 1.1.2.15. Let \( \mathcal{C} \) be a pointed ∞-category which admits cofibers, and suppose that the suspension functor \( \Sigma \) is an equivalence. Then the translation functor of Notation 1.1.2.8 and the class of distinguished triangles of Definition 1.1.2.12 endow \( h\mathcal{C} \) with the structure of a triangulated category.

Remark 1.1.2.16. The hypotheses of Theorem 1.1.2.15 hold whenever \( \mathcal{C} \) is stable. In fact, the hypotheses of Theorem 1.1.2.15 are equivalent to the stability of \( \mathcal{C} \): see Corollary 1.4.2.27.
Proof. We must verify that Verdier’s axioms (TR1) through (TR4) are satisfied.

(TR1) Let $\mathcal{E} \subseteq \text{Fun}(\Delta^1 \times \Delta^2, \mathcal{C})$ be the full subcategory spanned by those diagrams

$$
\begin{array}{ccc}
X & \xrightarrow{f} & Y & \xrightarrow{} 0 \\
\downarrow & & \downarrow & & \downarrow \\
0' & \xrightarrow{} Z & \xrightarrow{} W \\
\end{array}
$$

of the form considered in Definition 1.1.2.12, and let $e : \mathcal{E} \to \text{Fun}(\Delta^1, \mathcal{C})$ be the restriction to the upper left horizontal arrow. Repeated use of Proposition T.4.3.2.15 implies $e$ is a trivial fibration. In particular, every morphism $f : X \to Y$ can be completed to a diagram belonging to $\mathcal{E}$. This proves (a). Part (b) is obvious, and (c) follows from the observation that if $f = \text{id}_X$, then the object $Z$ in the above diagram is a zero object of $\mathcal{C}$.

(TR2) Suppose that

$$
X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1]
$$

is a distinguished triangle in $\text{hC}$, corresponding to a diagram $\sigma \in \mathcal{E}$ as depicted above. Extend $\sigma$ to a diagram

$$
\begin{array}{ccc}
X & \xrightarrow{} Y & \xrightarrow{} 0 \\
\downarrow & & \downarrow & & \downarrow \\
0' & \xrightarrow{} Z & \xrightarrow{} W \\
& & \downarrow{u} & & \\
0'' & \xrightarrow{} V \\
\end{array}
$$

where the lower right square is a pushout and $0''$ is a zero object of $\mathcal{C}$. We have a map between the squares

$$
\begin{array}{ccc}
X & \xrightarrow{} 0 & \xrightarrow{} Y & \xrightarrow{} 0 \\
\downarrow & & \downarrow & & \downarrow \\
0' & \xrightarrow{} W & \xrightarrow{} 0'' & \xrightarrow{} V \\
\end{array}
$$

which induces a commutative diagram in the homotopy category $\text{hC}$

$$
\begin{array}{ccc}
W & \xrightarrow{} X[1] \\
\downarrow{u} & & \downarrow{f[1]} \\
V & \xrightarrow{} Y[1] \\
\end{array}
$$

where the horizontal arrows are isomorphisms. Applying Lemma 1.1.2.14 to the rectangle on the right of the large diagram, we conclude that

$$
Y \xrightarrow{g} Z \xrightarrow{h} X[1] \xrightarrow{-f[1]} Y[1]
$$

is a distinguished triangle in $\text{hC}$.

Conversely, suppose that

$$
Y \xrightarrow{g} Z \xrightarrow{h} X[1] \xrightarrow{-f[1]} Y[1]
$$

is a distinguished triangle in $\text{hC}$. Since the functor $\Sigma : \mathcal{C} \to \mathcal{C}$ is an equivalence, we conclude that the triangle

$$
Y[-2] \xrightarrow{g[-2]} Z[-2] \xrightarrow{h[-2]} X[-1] \xrightarrow{-f[-1]} Y[-1]
$$
is distinguished. Applying the preceding argument five times, we conclude that the triangle
\[ X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1] \]
is distinguished, as desired.

**(TR3)** Suppose we are given distinguished triangles
\[ X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[1] \]
\[ X' \xrightarrow{f'} Y' \xrightarrow{g'} Z' \xrightarrow{h'} X'[1] \]
in \( \text{hC} \). Without loss of generality, we may suppose that these triangles are induced by diagrams \( \sigma, \sigma' \in \mathcal{E} \). Any commutative diagram
\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow & & \downarrow \\
X' & \xrightarrow{f'} & Y'
\end{array}
\]
in the homotopy category \( \text{hC} \) can be lifted (nonuniquely) to a square in \( \mathcal{C} \), which we may identify with a morphism \( \phi : e(\sigma) \rightarrow e(\sigma') \) in the \( \infty \)-category \( \text{Fun}(\Delta^1, \mathcal{C}) \). Since \( e \) is a trivial fibration of simplicial sets, \( \phi \) can be lifted to a morphism \( \sigma \rightarrow \sigma' \) in \( \mathcal{E} \), which determines a natural transformation of distinguished triangles
\[
\begin{array}{ccc}
X & \rightarrow & Y & \rightarrow & Z & \rightarrow & X[1] \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
X' & \rightarrow & Y' & \rightarrow & Z' & \rightarrow & X'[1].
\end{array}
\]

**(TR4)** Let \( f : X \rightarrow Y \) and \( g : Y \rightarrow Z \) be morphisms in \( \mathcal{C} \). In view of the fact that \( e : \mathcal{E} \rightarrow \text{Fun}(\Delta^1, \mathcal{C}) \) is a trivial fibration, any distinguished triangle in \( \text{hC} \) beginning with \( f, g, \) or \( g \circ f \) is uniquely determined up to (nonunique) isomorphism. Consequently, it will suffice to prove that there exist some triple of distinguished triangles which satisfies the conclusions of *(TR4)*. To prove this, we construct a diagram in \( \mathcal{C} \)
\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y & \xrightarrow{g} & Z & \xrightarrow{0} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \rightarrow & Y/X & \rightarrow & Z/X & \rightarrow & X'[1].
\end{array}
\]
where \( 0 \) is a zero object of \( \mathcal{C} \), and each square in the diagram is a pushout (more precisely, we apply Proposition T.4.3.2.15 repeatedly to construct a map from the nerve of the appropriate partially ordered set into \( \mathcal{C} \)). Restricting to appropriate rectangles contained in the diagram, we obtain isomorphisms \( X' \simeq X[1] \), \( Y' \simeq Y[1] \), \( (Y/X)' \simeq Y/X[1] \), and four distinguished triangles
\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \rightarrow & Y/X & \rightarrow & X[1] \\
Y & \xrightarrow{g} & Z \rightarrow & Z/Y & \rightarrow & Y[1] \\
X & \xrightarrow{g \circ f} & Z \rightarrow & Z/X & \rightarrow & X[1]
\end{array}
\]
1.1. FOUNDATIONS

\[ Y/X \to Z/X \to Z/Y \to Y/X[1]. \]

The commutativity in the homotopy category \( \mathcal{C} \) required by \((TR4)\) follows from the (stronger) commutativity of the above diagram in \( \mathcal{C} \) itself.

Remark 1.1.2.17. The definition of a stable \( \infty \)-category is quite a bit simpler than that of a triangulated category. In particular, the octahedral axiom \((TR4)\) is a consequence of \( \infty \)-categorical principles which are basic and easily motivated.

Notation 1.1.2.18. Let \( \mathcal{C} \) be a stable \( \infty \)-category containing a pair of objects \( X \) and \( Y \). We let \( \text{Ext}^n_{\mathcal{C}}(X,Y) \) denote the abelian group \( \text{Hom}_{\mathcal{C}}(X[-n],Y) \). If \( n \) is negative, this can be identified with the homotopy group \( \pi_{-n} \text{Map}_\mathcal{C}(X,Y) \). More generally, \( \text{Ext}^n_{\mathcal{C}}(X,Y) \) can be identified with the \((-n)\)th homotopy group of an appropriate spectrum of maps from \( X \) to \( Y \).

1.1.3 Closure Properties of Stable \( \infty \)-Categories

According to Definition 1.1.1.9, a pointed \( \infty \)-category \( \mathcal{C} \) is stable if it admits certain pushout squares and certain pullback squares, which are required to coincide with one another. Our goal in this section is to prove that a stable \( \infty \)-category \( \mathcal{C} \) admits all finite limits and colimits, and that the pushout squares in \( \mathcal{C} \) coincide with the pullback squares in general (Proposition 1.1.3.4). To prove this, we will need the following easy observation (which is quite useful in its own right):

Proposition 1.1.3.1. Let \( \mathcal{C} \) be a stable \( \infty \)-category, and let \( K \) be a simplicial set. Then the \( \infty \)-category \( \text{Fun}(K,\mathcal{C}) \) is stable.

Proof. This follows immediately from the fact that fibers and cofibers in \( \text{Fun}(K,\mathcal{C}) \) can be computed pointwise (Proposition T.5.1.2.2).

Definition 1.1.3.2. If \( \mathcal{C} \) is stable \( \infty \)-category, and \( \mathcal{C}_0 \) is a full subcategory containing a zero object and stable under the formation of fibers and cofibers, then \( \mathcal{C}_0 \) is itself stable. In this case, we will say that \( \mathcal{C}_0 \) is a stable subcategory of \( \mathcal{C} \).

Lemma 1.1.3.3. Let \( \mathcal{C} \) be a stable \( \infty \)-category, and let \( \mathcal{C}' \subseteq \mathcal{C} \) be a full subcategory which is stable under cofibers and under translations. Then \( \mathcal{C}' \) is a stable subcategory of \( \mathcal{C} \).

Proof. It will suffice to show that \( \mathcal{C}' \) is stable under fibers. Let \( f : X \to Y \) be a morphism in \( \mathcal{C} \). Theorem 1.1.2.15 shows that there is a canonical equivalence \( \text{fib}(f) \simeq \text{cofib}(f)[-1] \).

Proposition 1.1.3.4. Let \( \mathcal{C} \) be a pointed \( \infty \)-category. Then \( \mathcal{C} \) is stable if and only if the following conditions are satisfied:

(1) The \( \infty \)-category \( \mathcal{C} \) admits finite limits and colimits.

(2) A square

\[
\begin{array}{ccc}
X & \longrightarrow & Y \\
\downarrow & & \downarrow \\
X' & \longrightarrow & Y'
\end{array}
\]

in \( \mathcal{C} \) is a pushout if and only if it is a pullback.
Proof. Condition (1) implies the existence of fibers and cofibers in \( \mathcal{C} \), and condition (2) implies that a triangle in \( \mathcal{C} \) is a fiber sequence if and only if it is a cofiber sequence. This proves the “if” direction.

Suppose now that \( \mathcal{C} \) is stable. We begin by proving (1). It will suffice to show that \( \mathcal{C} \) admits finite colimits; the dual argument will show that \( \mathcal{C} \) admits finite limits as well. According to Proposition T.4.4.3.2, it will suffice to show that \( \mathcal{C} \) admits coequalizers and finite coproducts. The existence of finite coproducts was established in Lemma 1.1.2.10. We now conclude by observing that a coequalizer for a diagram

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{f'} & & \downarrow \\
Y & & Y
\end{array}
\]

can be identified with \( \text{cofib}(f - f') \).

We now show that every pushout square in \( \mathcal{C} \) is a pullback; the converse will follow by a dual argument. Let \( \mathcal{D} \subseteq \text{Fun}(\Delta^1 \times \Delta^1, \mathcal{C}) \) be the full subcategory spanned by the pullback squares. Then \( \mathcal{D} \) is stable under finite limits and under translations. It follows from Lemma 1.1.3.3 that \( \mathcal{D} \) is a stable subcategory of \( \text{Fun}(\Delta^1 \times \Delta^1, \mathcal{C}) \).

Let \( i : \Lambda^2_0 \hookrightarrow \Delta^1 \times \Delta^1 \) be the inclusion, and let \( i_! : \text{Fun}(\Lambda^2_0, \mathcal{C}) \rightarrow \text{Fun}(\Delta^1 \times \Delta^1, \mathcal{C}) \) be a functor of left Kan extension. Then \( i_! \) preserves finite colimits, and is therefore exact (Proposition 1.1.4.1). Let \( \mathcal{D}' = i_!^{-1} \mathcal{D} \). Then \( \mathcal{D}' \) is a stable subcategory of \( \text{Fun}(\Lambda^2_0, \mathcal{C}) \); we wish to show that \( \mathcal{D}' = \text{Fun}(\Lambda^2_0, \mathcal{C}) \). To prove this, we observe that any diagram

\[
\begin{array}{ccc}
x' & \leftarrow & x \\
\downarrow & & \downarrow \\
x'' & \rightarrow & x''
\end{array}
\]

can be obtained as a (finite) colimit

\[
e_{X, X'} \coprod e_{X, X''} \coprod e_{Z, Z'}
\]

where \( e_{X, X'} \in \text{Fun}(\Lambda^2_0, \mathcal{C}) \) denotes the diagram \( X \leftarrow X \rightarrow X \), \( e'_{Z, Z'} \in \text{Fun}(\Lambda^2_0, \mathcal{C}) \) denotes the diagram \( Z \leftarrow 0 \rightarrow 0 \), and \( e'_{Z, Z'} \in \text{Fun}(\Lambda^2_0, \mathcal{C}) \) denotes the diagram \( 0 \leftarrow 0 \rightarrow Z \). It will therefore suffice to prove that a pushout of any of these five diagrams is also a pullback. This follows immediately from the following more general observation: any pushout square

\[
\begin{array}{ccc}
A & \xrightarrow{f} & A' \\
\downarrow & & \downarrow \\
B & \xrightarrow{g} & B'
\end{array}
\]

in an (arbitrary) \( \infty \)-category \( \mathcal{C} \) is also a pullback square, provided that \( f \) is an equivalence.

Remark 1.1.3.5. Let \( \mathcal{C} \) be a stable \( \infty \)-category. Then \( \mathcal{C} \) admits finite products and finite coproducts (Proposition 1.1.3.4). Moreover, for any pair of objects \( X, Y \in \mathcal{C} \), there is a canonical equivalence

\[
X \amalg Y \rightarrow X \times Y,
\]

given by the matrix

\[
\begin{bmatrix}
id_X & 0 \\
0 & id_Y
\end{bmatrix}.
\]

Theorem 1.1.2.15 implies that this map is an equivalence. We will sometimes use the notation \( X \oplus Y \) to denote a product or coproduct of \( X \) and \( Y \) in \( \mathcal{C} \).

We conclude this section by establishing a few closure properties for the class of stable \( \infty \)-categories.

Proposition 1.1.3.6. Let \( \mathcal{C} \) be a (small) stable \( \infty \)-category and let \( \kappa \) be a regular cardinal. Then the \( \infty \)-category \( \text{Ind}_\kappa(\mathcal{C}) \) is stable.
Proof. The functor \( j \) preserves finite limits and colimits (Propositions T.5.1.3.2 and T.5.3.5.14). It follows that \( j(0) \) is a zero object of \( \text{Ind}_\kappa(\mathcal{C}) \), so that \( \text{Ind}_\kappa(\mathcal{C}) \) is pointed.

We next show that every morphism \( f : X \to Y \) in \( \text{Ind}_\kappa(\mathcal{C}) \) admits a fiber and a cofiber. According to Proposition T.5.3.5.15, we may assume that \( f \) is a \( \kappa \)-filtered colimit of morphisms \( f_\alpha : X_\alpha \to Y_\alpha \) which belong to the essential image \( \mathcal{C}' \) of \( j \). Since \( j \) preserves fibers and cofibers, each of the maps \( f_\alpha \) has a fiber and a cofiber in \( \text{Ind}_\kappa \). It follows immediately that \( f \) has a cofiber (which can be written as a colimit of the cofibers of the maps \( f_\alpha \)). The existence of \( \text{fib}(f) \) is slightly more difficult. Choose a \( \kappa \)-filtered diagram \( p : I \to \text{Fun}(\Delta^1 \times \Delta^1, \mathcal{C}') \), where each \( p(\alpha) \) is a pullback square

\[
\begin{array}{ccc}
Z_\alpha & \rightarrow & 0 \\
\downarrow & & \downarrow \\
X_\alpha & \rightarrow & Y_\alpha
\end{array}
\]

Let \( \sigma \) be a colimit of the diagram \( p \); we wish to show that \( \sigma \) is a pullback diagram in \( \text{Ind}_\kappa(\mathcal{C}) \). Since \( \text{Ind}_\kappa(\mathcal{C}) \) is stable under \( \kappa \)-small limits in \( \mathcal{P}(\mathcal{C}) \), it will suffice to show that \( \sigma \) is a pullback square in \( \mathcal{P}(\mathcal{C}) \). Since \( \mathcal{P}(\mathcal{C}) \) is an \( \infty \)-topos, filtered colimits in \( \mathcal{P}(\mathcal{C}) \) are left exact (Example T.7.3.4.7); it will therefore suffice to show that each \( p(\alpha) \) is a pullback diagram in \( \mathcal{P}(\mathcal{C}) \). This is obvious, since the inclusion \( \mathcal{C}' \subseteq \mathcal{P}(\mathcal{C}) \) preserves all limits which exist in \( \mathcal{C}' \) (Proposition T.5.1.3.2).

To complete the proof, we must show that a triangle in \( \text{Ind}_\kappa(\mathcal{C}) \) is a fiber sequence if and only if it is a cofiber sequence. Suppose we are given a fiber sequence

\[
\begin{array}{ccc}
Z & \rightarrow & 0 \\
\downarrow & & \downarrow \\
X & \rightarrow & Y
\end{array}
\]

in \( \text{Ind}_\kappa(\mathcal{C}) \). The above argument shows that we can write this triangle as a filtered colimit of fiber sequences

\[
\begin{array}{ccc}
Z_\alpha & \rightarrow & 0 \\
\downarrow & & \downarrow \\
X_\alpha & \rightarrow & Y_\alpha
\end{array}
\]

in \( \mathcal{C}' \). Since \( \mathcal{C}' \) is stable, we conclude that these triangles are also cofiber sequences. The original triangle is therefore a filtered colimit of cofiber sequences in \( \mathcal{C}' \), hence a cofiber sequence. The converse follows by the same argument. 

Corollary 1.1.3.7. Let \( \mathcal{C} \) be a stable \( \infty \)-category. Then the idempotent completion of \( \mathcal{C} \) is also stable.

Proof. According to Lemma T.5.4.2.4, we can identify the idempotent completion of \( \mathcal{C} \) with a full subcategory of \( \text{Ind}(\mathcal{C}) \) which is closed under shifts and finite colimits.

1.1.4 Exact Functors

Let \( F : \mathcal{C} \to \mathcal{C}' \) be a functor between stable \( \infty \)-categories. Suppose that \( F \) carries zero objects into zero objects. It follows immediately that \( F \) carries triangles into triangles. If, in addition, \( F \) carries fiber sequences to fiber sequences, then we will say that \( F \) is exact. The exactness of a functor \( F \) admits the following alternative characterizations:

Proposition 1.1.4.1. Let \( F : \mathcal{C} \to \mathcal{C}' \) be a functor between stable \( \infty \)-categories. The following conditions are equivalent:

Proof. 

1.1.4 Exact Functors
The functor $F$ is left exact. That is, $F$ commutes with finite limits.

(2) The functor $F$ is right exact. That is, $F$ commutes with finite colimits.

(3) The functor $F$ is exact.

Proof. We will prove that (2) $\iff$ (3); the equivalence (1) $\iff$ (3) will follow by a dual argument. The implication (2) $\implies$ (3) is obvious. Conversely, suppose that $F$ is exact. The proof of Proposition 1.1.3.4 shows that $F$ preserves coequalizers, and the proof of Lemma 1.1.2.10 shows that $F$ preserves finite coproducts. It follows that $F$ preserves all finite colimits (see the proof of Proposition T.4.4.3.2).

The identity functor from any stable $\infty$-category to itself is exact, and a composition of exact functors is exact. Consequently, there exists a subcategory $C_{\infty} \subseteq \text{Cat}_{\infty}$ in which the objects are stable $\infty$-categories and the morphisms are the exact functors. Our next few results concern the stability properties of this subcategory.

Proposition 1.1.4.2. Suppose given a homotopy Cartesian diagram of $\infty$-categories

$C' \xrightarrow{G'} C \xleftarrow{F'} D' \xrightarrow{G} D$.

Suppose further that $C$, $D'$, and $D$ are stable, and that the functors $F'$ and $G$ are exact. Then:

(1) The $\infty$-category $C'$ is stable.

(2) The functors $F'$ and $G'$ are exact.

(3) If $E$ is a stable $\infty$-category, then a functor $H : E \to C'$ is exact if and only if the functors $F' \circ H$ and $G' \circ H$ are exact.

Proof. Combine Proposition 1.1.3.4 with Lemma T.5.4.5.5.

Proposition 1.1.4.3. Let $\{C_\alpha\}_{\alpha \in A}$ be a collection of stable $\infty$-categories. Then the product

$C = \prod_{\alpha \in A} C_\alpha$

is stable. Moreover, for any stable $\infty$-category $D$, a functor $F : D \to C$ is exact if and only if each of the compositions

$D \xrightarrow{F} C_\alpha \xrightarrow{F} C$

is an exact functor.

Proof. This follows immediately from the fact that limits and colimits in $C$ are computed pointwise.

Theorem 1.1.4.4. The $\infty$-category $\text{Cat}_{\infty}^{\text{Ex}}$ admits small limits, and the inclusion

$\text{Cat}_{\infty}^{\text{Ex}} \subseteq \text{Cat}_{\infty}$

preserves small limits.

Proof. Using Propositions 1.1.4.2 and 1.1.4.3, one can repeat the argument used to prove Proposition T.5.4.7.3.

We have the following analogue of Theorem 1.1.4.4.
Proposition 1.1.4.5. Let \( p : X \to S \) be an inner fibration of simplicial sets. Suppose that:

(i) For each vertex \( s \) of \( S \), the fiber \( X_s = X \times_S \{ s \} \) is a stable \( \infty \)-category.

(ii) For every edge \( s \to s' \) in \( S \), the restriction \( X \times_S \Delta^1 \to \Delta^1 \) is a coCartesian fibration, associated to an exact functor \( X_s \to X_{s'} \).

Then:

1. The \( \infty \)-category \( \text{Map}_S(S,X) \) of sections of \( p \) is stable.
2. If \( \mathcal{C} \) is an arbitrary stable \( \infty \)-category, and \( f : \mathcal{C} \to \text{Map}_S(S,X) \) induces an exact functor \( \mathcal{C} \to \text{Map}_S(S,X) \to X_s \) for every vertex \( s \) of \( S \), then \( f \) is exact.
3. For every set \( E \) of edges of \( S \), let \( Y(E) \subseteq \text{Map}_S(S,X) \) be the full subcategory spanned by those sections \( f : S \to X \) of \( p \) with the following property:

\[ \begin{align*}
&(*) \text{ For every } e \in E, f \text{ carries } e \text{ to a } p_e\text{-coCartesian edge of the fiber product } X \times_S \Delta^1, \text{ where } p_e : X \times_S \Delta^1 \to \Delta^1 \text{ denotes the projection.}
\end{align*} \]

Then each \( Y(E) \) is a stable subcategory of \( \text{Map}_S(S,X) \).

Proof. Combine Proposition T.5.4.7.11, Theorem 1.1.4.4, and Proposition 1.1.3.1. \( \square \)

Proposition 1.1.4.6. The \( \infty \)-category \( \text{Cat}^\text{Ex}_\infty \) admits small filtered colimits, and the inclusion \( \text{Cat}^\text{Ex}_\infty \subseteq \text{Cat}_\infty \) preserves small filtered colimits.

Proof. Let \( I \) be a filtered \( \infty \)-category, \( p : I \to \text{Cat}^\text{Ex}_\infty \) a diagram, which we will indicate by \( \{ \mathcal{C}_I \}_{I \in \mathcal{I}} \), and \( \mathcal{C} \) a colimit of the induced diagram \( I \to \text{Cat}_\infty \). We must prove:

(i) The \( \infty \)-category \( \mathcal{C} \) is stable.

(ii) Each of the canonical functors \( \theta_I : \mathcal{C}_I \to \mathcal{C} \) is exact.

(iii) Given an arbitrary stable \( \infty \)-category \( \mathcal{D} \), a functor \( f : \mathcal{C} \to \mathcal{D} \) is exact if and only if each of the composite functors \( \mathcal{C}_I \xrightarrow{\theta_I} \mathcal{C} \to \mathcal{D} \) is exact.

In view of Proposition 1.1.4.1, (ii) and (iii) follow immediately from Proposition T.5.5.7.11. The same result implies that \( \mathcal{C} \) admits finite limits and colimits, and that each of the functors \( \theta_I \) preserves finite limits and colimits.

To prove that \( \mathcal{C} \) has a zero object, we select an object \( I \in \mathcal{I} \). The functor \( \mathcal{C}_I \to \mathcal{C} \) preserves initial and final objects. Since \( \mathcal{C}_I \) has a zero object, so does \( \mathcal{C} \).

We will complete the proof by showing that every fiber sequence in \( \mathcal{C} \) is a cofiber sequence (the converse follows by the same argument). Fix a morphism \( f : X \to Y \) in \( \mathcal{C} \). Without loss of generality, we may suppose that there exists \( I \in \mathcal{I} \) and a morphism \( \tilde{f} : \tilde{X} \to \tilde{Y} \) in \( \mathcal{C}_I \) such that \( f = \theta_I(\tilde{f}) \) (Proposition T.5.4.1.2). Form a pullback diagram \( \tilde{\sigma} \):

\[
\begin{array}{ccc}
\tilde{W} & \longrightarrow & \tilde{X} \\
\downarrow & & \downarrow \\
0 & \longrightarrow & \tilde{Y}
\end{array}
\]

in \( \mathcal{C}_I \). Since \( \mathcal{C}_I \) is stable, this diagram is also a pushout. It follows that \( \theta_I(\tilde{\sigma}) \) is a triangle \( W \to X \xrightarrow{f} Y \) which is both a fiber sequence and a cofiber sequence in \( \mathcal{C} \). \( \square \)
1.2 Stable ∞-Categories and Homological Algebra

Let $\mathcal{A}$ be an abelian category with enough projective objects. In §1.3.2, we will explain how to associate to $\mathcal{A}$ a stable ∞-category $\mathcal{D}^-(\mathcal{A})$, whose objects are (right-bounded) chain complexes of projective objects of $\mathcal{A}$. The homotopy category $\mathcal{D}^-(\mathcal{A})$ is a triangulated category, which is usually called the derived category of $\mathcal{A}$.

We can recover $\mathcal{A}$ as a full subcategory of the triangulated category $\mathcal{h}\mathcal{D}^-(\mathcal{A})$ (or even as a full subcategory of the ∞-category $\mathcal{D}^-(\mathcal{A})$): namely, $\mathcal{A}$ is equivalent to the full subcategory spanned by those chain complexes $P_{n1}$ satisfying $H_n(P_n) \simeq 0$ for $n \neq 0$. This subcategory can be described as the intersection

$$\mathcal{D}^-(\mathcal{A})_{\geq 0} \cap \mathcal{D}^-(\mathcal{A})_{\leq 0},$$

where $\mathcal{D}^-(\mathcal{A})_{\leq 0}$ is defined to be the full subcategory spanned by those chain complexes $P_n$ with $H_n(P_n) \simeq 0$ for $n > 0$, and $\mathcal{D}^-(\mathcal{A})_{\geq 0}$ is spanned by those chain complexes with $H_n(P_n) \simeq 0$ for $n < 0$.

In §1.2.1, we will axiomatize the essence of the situation by reviewing the notion of a t-structure on a stable ∞-category $\mathcal{C}$. A t-structure on $\mathcal{C}$ is a pair of full subcategories $\mathcal{C}_{\geq 0}, \mathcal{C}_{\leq 0}$ satisfying some axioms which reflect the idea that objects of $\mathcal{C}_{\geq 0}$ ($\mathcal{C}_{\leq 0}$) are "concentrated in nonnegative (nonpositive) degrees" (see Definition 1.2.1.1). In this case, one can show that the intersection $\mathcal{C}_{\geq 0} \cap \mathcal{C}_{\leq 0}$ is equivalent to the nerve of an abelian category, which we call the heart of $\mathcal{C}$ and denote by $\mathcal{C}^0$. To any object $X \in \mathcal{C}$, we can associate homotopy objects $\pi_n X \in \mathcal{C}^0$ (in the special case $\mathcal{C} = \mathcal{D}^-(\mathcal{A})$, the functor $\pi_n$ associates to each chain complex $P_n$ its $n$th homology $H_n(P_n)$).

If $\mathcal{C}$ is a stable ∞-category equipped with a t-structure, then it is often possible to relate questions about $\mathcal{C}$ to homological algebra in the abelian category $\mathcal{C}^0$. In §1.2.2, we give an illustration of this principle, by showing that every filtration on an object $X \in \mathcal{C}$ determines a spectral sequence $\{E_{r, q}^p, d_r\}_{r \geq 1}$ in the abelian category $\mathcal{C}^0$, which (in good cases) converges to the homotopy objects $\pi_n X$ (Proposition 1.2.2.7). The first page of this spectral sequence has a reasonably explicit description in terms of the homotopy objects of the successive quotients for the filtration of $X$. In practice, it is often difficult to describe $E_{r, q}$ when $r > 2$. However, there is a convenient description in the case $r = 2$, at least when $X$ is given as the geometric realization of a simplicial object $X_\bullet$, of $\mathcal{C}$ (equipped with the corresponding skeletal filtration). In §1.2.4 we will show that this is essentially no loss of generality: if $\mathcal{C}$ is a stable ∞-category, then every nonnegatively filtered object $X$ of $\mathcal{C}$ can be realized as the geometric realization of a simplicial object of $\mathcal{C}$, equipped with the skeletal filtration (Theorem 1.2.4.1). This assertion can be regarded as an ∞-categorical analogue of the classical Dold-Kan correspondence between simplicial objects and chain complexes in an abelian category, which we review in §1.2.3.

1.2.1 t-Structures on Stable ∞-Categories

Let $\mathcal{C}$ be an ∞-category. Recall that we say a full subcategory $\mathcal{C}' \subseteq \mathcal{C}$ is a localization of $\mathcal{C}$ if the inclusion functor $\mathcal{C}' \subseteq \mathcal{C}$ has a left adjoint (§T.5.2.7). In this section, we will introduce a special class of localizations, called t-localizations, in the case where $\mathcal{C}$ is stable. We will further show that there is a bijective correspondence between t-localizations of $\mathcal{C}$ and t-structures on the triangulated category $\mathcal{h}\mathcal{C}$. We begin with a review of the classical theory of t-structures; for a more thorough introduction we refer the reader to [13].

Definition 1.2.1.1. Let $\mathcal{D}$ be a triangulated category. A t-structure on $\mathcal{D}$ is defined to be a pair of full subcategories $\mathcal{D}_{\geq 0}, \mathcal{D}_{\leq 0}$ (always assumed to be stable under isomorphism) having the following properties:

1. For $X \in \mathcal{D}_{\geq 0}$ and $Y \in \mathcal{D}_{\leq 0}$, we have $\text{Hom}_\mathcal{D}(X, Y[-1]) = 0$.
2. We have inclusions $\mathcal{D}_{\geq 0}[1] \subseteq \mathcal{D}_{\geq 0}, \mathcal{D}_{\leq 0}[-1] \subseteq \mathcal{D}_{\leq 0}$.
3. For any $X \in \mathcal{D}$, there exists a fiber sequence $X' \to X \to X''$ where $X' \in \mathcal{D}_{\geq 0}$ and $X'' \in \mathcal{D}_{\leq 0}[-1]$.

Notation 1.2.1.2. If $\mathcal{D}$ is a triangulated category equipped with a t-structure, we will write $\mathcal{D}_{\geq n}$ for $\mathcal{D}_{\geq 0}[n]$ and $\mathcal{D}_{\leq n}$ for $\mathcal{D}_{\leq 0}[n]$. Observe that we use a homological indexing convention.
Remark 1.2.1.3. In Definition 1.2.1.1, either of the full subcategories $\mathcal{D}_{\geq 0}, \mathcal{D}_{\leq 0} \subseteq \mathcal{D}$ determines the other. For example, an object $X \in \mathcal{D}$ belongs to $\mathcal{D}_{\leq -1}$ if and only if $\text{Hom}_\mathcal{D}(Y, X)$ vanishes for all $Y \in \mathcal{D}_{\geq 0}$.

Definition 1.2.1.4. Let $\mathcal{C}$ be a stable $\infty$-category. A t-structure on $\mathcal{C}$ is a t-structure on the homotopy category $h\mathcal{C}$. If $\mathcal{C}$ is equipped with a t-structure, we let $\mathcal{C}_{\geq n}$ and $\mathcal{C}_{\leq n}$ denote the full subcategories of $\mathcal{C}$ spanned by those objects which belong to $(h\mathcal{C})_{\geq n}$ and $(h\mathcal{C})_{\leq n}$, respectively.

Proposition 1.2.1.5. Let $\mathcal{C}$ be a stable $\infty$-category equipped with a t-structure. For each $n \in \mathbb{Z}$, the full subcategory $\mathcal{C}_{\leq n}$ is a localization of $\mathcal{C}$.

Proof. Without loss of generality, we may suppose $n = -1$. According to Proposition T.5.2.7.8, it will suffice to prove that for each $X \in \mathcal{C}$, there exists a map $f : X \to X''$, where $X'' \in \mathcal{C}_{\leq -1}$ and for each $Y \in \mathcal{C}_{\leq -1}$, the map

$$\text{Map}_\mathcal{C}(X'', Y) \to \text{Map}_\mathcal{C}(X, Y)$$

is a weak homotopy equivalence. Invoking part (3) of Definition 1.2.1.1, we can choose $f$ to fit into a fiber sequence

$$X' \to X \xrightarrow{f} X''$$

where $X' \in \mathcal{C}_{\geq 0}$. According to Whitehead's theorem, we need to show that for every $k \leq 0$, the map

$$\text{Ext}^k_{\mathcal{C}}(X'', Y) \to \text{Ext}^k_{\mathcal{C}}(X, Y)$$

is an isomorphism of abelian groups. Using the long exact sequence associated to the fiber sequence above, we are reduced to proving that the groups $\text{Ext}^k_{\mathcal{C}}(X', Y)$ vanish for $k \leq 0$. We now use condition (2) of Definition 1.2.1.1 to conclude that $X'[-k] \in \mathcal{C}_{\geq 0}$. Condition (1) of Definition 1.2.1.1 now implies that

$$\text{Ext}^k_{\mathcal{C}}(X', Y) \simeq \text{Hom}_{h\mathcal{C}}(X'[-k], Y) \simeq 0.$$

\[ \square \]

Corollary 1.2.1.6. Let $\mathcal{C}$ be a stable $\infty$-category equipped with a t-structure. The full subcategories $\mathcal{C}_{\leq n} \subseteq \mathcal{C}$ are stable under all limits which exist in $\mathcal{C}$. Dually, the full subcategories $\mathcal{C}_{\geq n} \subseteq \mathcal{C}$ are stable under all colimits which exist in $\mathcal{C}$.

Notation 1.2.1.7. Let $\mathcal{C}$ be a stable $\infty$-category equipped with a t-structure. We will let $\tau_{\leq n}$ denote a left adjoint to the inclusion $\mathcal{C}_{\leq n} \subseteq \mathcal{C}$, and $\tau_{\geq n}$ a right adjoint to the inclusion $\mathcal{C}_{\geq n} \subseteq \mathcal{C}$.

Remark 1.2.1.8. Fix $n, m \in \mathbb{Z}$, and let $\mathcal{C}$ be a stable $\infty$-category equipped with a t-structure. Then the truncation functors $\tau_{\leq n}$, $\tau_{\geq n}$ map the full subcategory $\mathcal{C}_{\leq m}$ to itself. To prove this, we first observe that $\tau_{\leq n}$ is equivalent to the identity on $\mathcal{C}_{\leq m}$ if $m \leq n$, while if $m \geq n$ the essential image of $\tau_{\leq n}$ is contained in $\mathcal{C}_{\leq n} \subseteq \mathcal{C}_{\leq m}$. To prove the analogous result for $\tau_{\geq n}$, we observe that the proof of Proposition 1.2.1.5 implies that for each $X$, we have a fiber sequence

$$\tau_{\geq n} X \to X \xrightarrow{f} \tau_{\leq n-1} X.$$

If $X \in \mathcal{C}_{\leq m}$, then $\tau_{\leq n-1} X$ also belongs to $\mathcal{C}_{\leq m}$, so that $\tau_{\geq n} X \simeq \text{fib}(f)$ belongs to $\mathcal{C}_{\leq m}$ since $\mathcal{C}_{\leq m}$ is stable under limits.

Warning 1.2.1.9. In §T.5.5.6, we introduced for every $\infty$-category $\mathcal{C}$ a full subcategory $\tau_{\leq n} \mathcal{C}$ of $n$-truncated objects of $\mathcal{C}$. In that context, we used the symbol $\tau_{\leq n}$ to denote a left adjoint to the inclusion $\tau_{\leq n} \mathcal{C} \subseteq \mathcal{C}$. This is not compatible with Notation 1.2.1.7. In fact, if $\mathcal{C}$ is a stable $\infty$-category, then it has no nonzero truncated objects at all: if $X \in \mathcal{C}$ is nonzero, then the identity map from $X$ to itself determines a nontrivial homotopy class in $\pi_n \text{Map}_\mathcal{C}(X[-n], X)$, for all $n \geq 0$. Nevertheless, the two notations are consistent when restricted to $\mathcal{C}_{\geq 0}$, by virtue of the following observation:
• Let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a t-structure. An object \( X \in \mathcal{C}_{\geq 0} \) is \( k \)-truncated (as an object of \( \mathcal{C}_{\geq 0} \)) if and only if \( X \in \mathcal{C}_{\leq k} \).

In fact, we have the following more general statement: for any \( X \in \mathcal{C} \) and \( k \geq -1 \), \( X \) belongs to \( \mathcal{C}_{\leq k} \) if and only if \( \text{Map}_\mathcal{C}(Y, X) \) is \( k \)-truncated for every \( Y \in \mathcal{C}_{\geq 0} \). Because the latter condition is equivalent to the vanishing of \( \text{Ext}^{n}_\mathcal{C}(Y, X) \) for \( n < -k \), we can use the shift functor to reduce to the case where \( n = 0 \) and \( k = -1 \), which is addressed by Remark 1.2.1.3.

Let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a t-structure, and let \( n, m \in \mathbb{Z} \). Remark 1.2.1.8 implies that we have a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{C}_{\geq n} & \longrightarrow & \mathcal{C} \\
\tau_{\leq m} & \downarrow & \tau_{\leq m} \\
\mathcal{C}_{\geq n} \cap \mathcal{C}_{\leq m} & \longrightarrow & \mathcal{C}_{\leq n}.
\end{array}
\]

As explained in §7.3.1, we get an induced transformation of functors

\[ \theta : \tau_{\leq m} \circ \tau_{\geq n} \rightarrow \tau_{\geq n} \circ \tau_{\leq m}. \]

**Proposition 1.2.1.10.** Let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a t-structure. Then the natural transformation

\[ \theta : \tau_{\leq m} \circ \tau_{\geq n} \rightarrow \tau_{\geq n} \circ \tau_{\leq m} \]

is an equivalence of functors \( \mathcal{C} \rightarrow \mathcal{C}_{\leq m} \cap \mathcal{C}_{\geq n} \).

**Proof.** This is a classical fact concerning triangulated categories; we include a proof for completeness. Fix \( X \in \mathcal{C} \); we wish to show that

\[ \theta(X) : \tau_{\leq m} \tau_{\geq n} X \rightarrow \tau_{\geq n} \tau_{\leq m} X \]

is an isomorphism in the homotopy category of \( \mathcal{C}_{\leq m} \cap \mathcal{C}_{\geq n} \). If \( m < n \), then both sides are zero and there is nothing to prove; let us therefore assume that \( m \geq n \). Fix \( Y \in \mathcal{C}_{\leq m} \cap \mathcal{C}_{\geq n} \); it will suffice to show that composition with \( \theta(X) \) induces an isomorphism

\[ \text{Ext}^0_\mathcal{C}(\tau_{\geq n} \tau_{\leq m} X, Y) \rightarrow \text{Ext}^0_\mathcal{C}(\tau_{\leq m} \tau_{\geq n} X, Y) \simeq \text{Ext}^0_\mathcal{C}(\tau_{\geq n} X, Y). \]

We have a map of long exact sequences

\[
\begin{align*}
\text{Ext}^0_\mathcal{C}(\tau_{\leq n-1} \tau_{\leq m} X, Y) & \xrightarrow{f_0} \text{Ext}^0_\mathcal{C}(\tau_{\leq n-1} X, Y) \\
\text{Ext}^0_\mathcal{C}(\tau_{\leq m} X, Y) & \xrightarrow{f_1} \text{Ext}^0_\mathcal{C}(X, Y) \\
\text{Ext}^0_\mathcal{C}(\tau_{\geq n} \tau_{\leq m} X, Y) & \xrightarrow{f_2} \text{Ext}^0_\mathcal{C}(\tau_{\geq n} X, Y) \\
\text{Ext}^1_\mathcal{C}(\tau_{\leq n-1} \tau_{\leq m} X, Y) & \xrightarrow{f_3} \text{Ext}^1_\mathcal{C}(\tau_{\leq n-1} X, Y) \\
\text{Ext}^1_\mathcal{C}(\tau_{\leq m} X, Y) & \xrightarrow{f_4} \text{Ext}^1_\mathcal{C}(X, Y).
\end{align*}
\]

Since \( m \geq n \), the natural transformation \( \tau_{\leq n-1} \rightarrow \tau_{\leq n-1} \tau_{\leq m} \) is an equivalence of functors; this proves that \( f_0 \) and \( f_3 \) are bijective. Since \( Y \in \mathcal{C}_{\leq m} \), \( f_1 \) is bijective and \( f_4 \) is injective. It follows from the “five lemma” that \( f_2 \) is bijective, as desired. \( \square \)
**Definition 1.2.1.11.** Let $\mathcal{C}$ be a stable $\infty$-category equipped with a $t$-structure. The *heart* $\mathcal{C}^0$ of $\mathcal{C}$ is the full subcategory $\mathcal{C}_{\geq 0} \cap \mathcal{C}_{\leq 0} \subseteq \mathcal{C}$. For each $n \in \mathbb{Z}$, we let $\tau_n : \mathcal{C} \to \mathcal{C}^0$ denote the functor $\tau_{\leq 0} \circ \tau_{\geq 0} \simeq \tau_{\geq 0} \circ \tau_{\leq 0}$, and we let $\pi_n : \mathcal{C} \to \mathcal{C}^0$ denote the composition of $\tau_0$ with the shift functor $X \mapsto X[-n]$. 

**Remark 1.2.1.12.** Let $\mathcal{C}$ be a stable $\infty$-category equipped with a $t$-structure, and let $X,Y \in \mathcal{C}^0$. The homotopy group $\pi_n \Map_\mathcal{C}(X,Y) \simeq \Ext^{-n}_\mathcal{C}(X,Y)$ vanishes for $n > 0$. It follows that $\mathcal{C}^0$ is equivalent to (the nerve of) its homotopy category $\h\mathcal{C}^0$. The category $\h\mathcal{C}^0$ is abelian ([13]). We will often abuse terminology by identifying $\mathcal{C}^0$ with the abelian category $\h\mathcal{C}^0$.

**Warning 1.2.1.13.** The definition of a $t$-structure on a triangulated category was introduced in [13]. However, the notation of [13] is slightly different from the notation employed here. We use homological rather than cohomological indexing conventions. Moreover, if $\mathcal{C}$ is a stable $\infty$-category equipped with a $t$-structure and $X \in \mathcal{C}$, then we denote the corresponding objects $\tau_{\leq 0}\tau_{\geq 0}X[-n]$ by $\pi_nX$, rather than $H_n(X)$. This notation reflects our emphasis in this book: the stable $\infty$-categories of greatest interest to us are those which arise in stable homotopy theory (see §1.4), rather than those which arise in homological algebra.

Let $\mathcal{C}$ be a stable $\infty$-category. In view of Remark 1.2.1.3, $t$-structures on $\mathcal{C}$ are determined by the corresponding localizations $\mathcal{C}_{\leq 0} \subseteq \mathcal{C}$. However, not every localization of $\mathcal{C}$ arises in this way. Recall (see §T.5.5.4) that every localization of $\mathcal{C}$ has the form $S^{-1}\mathcal{C}$, where $S$ is an appropriate collection of morphisms of $\mathcal{C}$. Here $S^{-1}\mathcal{C}$ denotes the full subcategory of $\mathcal{C}$ spanned by $S$-local objects, where an object $X \in \mathcal{C}$ is said to be $S$-local if and only if, for each $f : Y' \to Y$ in $S$, composition with $f$ induces a homotopy equivalence

$$\Map_\mathcal{C}(Y,X) \to \Map_\mathcal{C}(Y',X).$$

If $\mathcal{C}$ is stable, then we extend the morphism $f$ to a fiber sequence

$$Y' \to Y \to Y'',$$

and we have an associated long exact sequence

$$\ldots \to \Ext^i_\mathcal{C}(Y'',X) \to \Ext^i_\mathcal{C}(Y,X) \xrightarrow{\theta} \Ext^{i+1}_\mathcal{C}(Y',X) \to \Ext^{i+1}_\mathcal{C}(Y'',X) \to \ldots$$

The requirement that $X$ be $\{f\}$-local amounts to the condition that $\theta_i$ be an isomorphism for $i \leq 0$. Using the long exact sequence, we see that if $X$ is $\{f\}$-local, then $\Ext^{i}_\mathcal{C}(Y'',X) = 0$ for $i \leq 0$. Conversely, if $\Ext^{i}_\mathcal{C}(Y'',X) = 0$ for $i \leq 1$, then $X$ is $\{f\}$-local. Experience suggests that it is usually more natural to require the vanishing of the groups $\Ext^{i}_\mathcal{C}(Y'',X)$ than it is to require that the maps $\theta_i$ be isomorphisms. Of course, if $Y'$ is a zero object of $\mathcal{C}$, then the distinction between these conditions disappears.

**Definition 1.2.1.14.** Let $\mathcal{C}$ be an $\infty$-category which admits pushouts. We will say that a collection $S$ of morphisms of $\mathcal{C}$ is *quasisaturated* if it satisfies the following conditions:

1. Every equivalence in $\mathcal{C}$ belongs to $S$.
2. Given a $2$-simplex $\Delta^2 \to \mathcal{C}$

$$
\begin{array}{ccc}
X & \xrightarrow{h} & Z \\
\downarrow^{f} & & \downarrow^{g} \\
Y & \xleftarrow{\theta} & \\
\end{array}
$$

if any two of $f$, $g$, and $h$ belongs to $S$, then so does the third.

3. Given a pushout diagram

$$
\begin{array}{ccc}
X & \xrightarrow{f} & X' \\
\downarrow^{f} & & \downarrow^{f'} \\
Y & \xrightarrow{\theta} & Y', \\
\end{array}
$$

if $f \in S$, then $f' \in S$. 

CHAPTER 1. STABLE ∞-CATEGORIES

Any intersection of quasisaturated collections of morphisms is quasisaturated. Consequently, for any collection of morphisms \( S \) there is a smallest quasisaturated collection \( \overline{S} \) containing \( S \). We will say that \( \overline{S} \) is the quasisaturated collection of morphisms generated by \( S \).

**Definition 1.2.1.15.** Let \( \mathcal{C} \) be a stable ∞-category. A full subcategory \( \mathcal{C}' \subseteq \mathcal{C} \) is closed under extensions if, for every fiber sequence triangle

\[ X \to Y \to Z \]

such that \( X \) and \( Z \) belong to \( \mathcal{C}' \), the object \( Y \) also belongs to \( \mathcal{C}' \).

We observe that if \( \mathcal{C} \) is as in Definition 1.2.1.14 and \( L : \mathcal{C} \to \mathcal{C} \) is a localization functor, then the collection of all morphisms \( f \) of \( \mathcal{C} \) such that \( L(f) \) is an equivalence is quasisaturated.

**Proposition 1.2.1.16.** Let \( \mathcal{C} \) be a stable ∞-category, let \( L : \mathcal{C} \to \mathcal{C} \) be a localization functor, and let \( S \) be the collection of morphisms \( f \) in \( \mathcal{C} \) such that \( L(f) \) is an equivalence. The following conditions are equivalent:

1. There exists a collection of morphisms \( \{ f : 0 \to X \} \) which generates \( S \) (as a quasisaturated collection of morphisms).
2. The collection of morphisms \( \{ 0 \to X : L(X) \simeq 0 \} \) generates \( S \) (as a quasisaturated collection of morphisms).
3. The essential image of \( L \) is closed under extensions.
4. For any \( A \in \mathcal{C} \), \( B \in L \mathcal{C} \), the natural map \( \text{Ext}^1(LA,B) \to \text{Ext}^1(A,B) \) is injective.
5. The full subcategories \( \mathcal{C}_{\geq 0} = \{ A : LA \simeq 0 \} \) and \( \mathcal{C}_{\leq -1} = \{ A : LA \simeq A \} \) determine a t-structure on \( \mathcal{C} \).

**Proof.** The implication (1) \( \Rightarrow \) (2) is obvious. We next prove that (2) \( \Rightarrow \) (3). Suppose given a fiber sequence

\[ X \to Y \to Z \]

where \( X \) and \( Z \) are both \( S \)-local. We wish to prove that \( Y \) is \( S \)-local. In view of assumption (2), it will suffice to show that \( \text{Map}_{\mathcal{C}}(A,Y) \) is contractible, provided that \( L(A) \simeq 0 \). In other words, we must show that \( \text{Ext}^i(A,Y) \simeq 0 \) for \( i \leq 0 \). We now observe that there is an exact sequence

\[ \text{Ext}^i(A,X) \to \text{Ext}^i(A,Y) \to \text{Ext}^i(A,Z) \]

where the outer groups vanish, since \( X \) and \( Z \) are \( S \)-local and the map \( 0 \to A \) belongs to \( S \).

We next show that (3) \( \Rightarrow \) (4). Let \( B \in L \mathcal{C} \), and let \( \eta \in \text{Ext}_{\mathcal{C}}^1(LA,B) \) classify a distinguished triangle

\[ B \to C \xrightarrow{g} LA \xrightarrow{\eta} B[1]. \]

Condition (3) implies that \( C \in L \mathcal{C} \). If the image of \( \eta \) in \( \text{Ext}^1_{\mathcal{C}}(A,B) \) is trivial, then the localization map \( A \to LA \) factors as a composition

\[ A \xrightarrow{f} C \xrightarrow{g} LA. \]

Applying \( L \) to this diagram (and using the fact that \( C \) is local) we conclude that the map \( g \) admits a section, so that \( \eta = 0 \).

We now claim that (4) \( \Rightarrow \) (5). Assume (4), and define \( \mathcal{C}_{\geq 0}, \mathcal{C}_{\leq -1} \) as in (5). We will show that the axioms of Definition 1.2.1.1 are satisfied:

- If \( X \in \mathcal{C}_{\geq 0} \) and \( Y \in \mathcal{C}_{\leq -1} \), then \( \text{Ext}^0_{\mathcal{C}}(X,Y) \simeq \text{Ext}^0_{\mathcal{C}}(LX,Y) \simeq \text{Ext}^0_{\mathcal{C}}(0,Y) \simeq 0 \).
- Since \( \mathcal{C}_{\leq -1} \) is a localization of \( \mathcal{C} \), it is stable under limits, so that \( \mathcal{C}_{\leq -1}[{-1}] \subseteq \mathcal{C}_{\leq -1} \). Similarly, since the functor \( L : \mathcal{C} \to \mathcal{C}_{\leq -1} \) preserves all colimits which exist in \( \mathcal{C} \), the subcategory \( \mathcal{C}_{\geq 0} \) is stable under finite colimits, so that \( \mathcal{C}_{\geq 0}[1] \subseteq \mathcal{C}_{\geq 0} \).
Let $X \in \mathcal{C}$, and form a fiber sequence

$$X' \to X \to LX.$$ 

We claim that $X' \in \mathcal{C}_{\geq 0}$; in other words, that $LX' = 0$. For this, it suffices to show that for all $Y \in L\mathcal{C}$, the morphism space

$$\text{Ext}^0_{\mathcal{C}}(LX', Y) = 0.$$

Since $Y$ is local, we have isomorphisms

$$\text{Ext}^0_{\mathcal{C}}(LX', Y) \cong \text{Ext}^0_{\mathcal{C}}(X', Y) \cong \text{Ext}^1_{\mathcal{C}}(X'[1], Y).$$

We now observe that there is a long exact sequence

$$\text{Ext}^0_{\mathcal{C}}(LX, Y) \xrightarrow{f} \text{Ext}^0_{\mathcal{C}}(X, Y) \to \text{Ext}^1_{\mathcal{C}}(X'[1], Y) \to \text{Ext}^1_{\mathcal{C}}(LX, Y) \xrightarrow{f'} \text{Ext}^1_{\mathcal{C}}(X, Y).$$

Here $f$ is bijective (since $Y$ is local) and $f'$ is injective (in virtue of assumption (4)).

We conclude by showing that (5) $\Rightarrow$ (1). Let $S'$ be the smallest quasisaturated collection of morphisms which contains the zero map $0 \to A$, for every $A \in \mathcal{C}_{\geq 0}$. We wish to prove that $S = S'$. For this, we choose an arbitrary morphism $u : X \to Y$ belonging to $S$. Then $Lu : LX \to LY$ is an equivalence, so we have a pushout diagram

$$
\begin{array}{ccc}
X' & \xrightarrow{u'} & Y' \\
\downarrow & & \downarrow \\
X & \xrightarrow{u} & Y,
\end{array}
$$

where $X'$ and $Y'$ are fibers of the respective localization maps $X \to LX$, $Y \to LY$. Consequently, it will suffice to prove that $u' \in S'$. Since $X', Y' \in \mathcal{C}_{\geq 0}$, this follows from the two-out-of-three property, applied to the diagram

$$
\begin{array}{ccc}
& & \text{0} \\
& \xrightarrow{u'} & \text{Y'} \\
\text{X'} \downarrow & & \downarrow
\end{array}
$$

Let $\mathcal{C}$ be a stable $\infty$-category equipped with a t-structure. We let $\mathcal{C}^+ = \bigcup \mathcal{C}_{\leq n} \subseteq \mathcal{C}$, $\mathcal{C}^- = \bigcup \mathcal{C}_{\geq -n}$, and $\mathcal{C}^b = \mathcal{C}^+ \cap \mathcal{C}^-$. It is easy to see that $\mathcal{C}^-$, $\mathcal{C}^+$, and $\mathcal{C}^b$ are stable subcategories of $\mathcal{C}$. We will say that $\mathcal{C}$ is left bounded if $\mathcal{C} = \mathcal{C}^+$, right bounded if $\mathcal{C} = \mathcal{C}^-$, and bounded if $\mathcal{C} = \mathcal{C}^b$.

At the other extreme, given a stable $\infty$-category $\mathcal{C}$ equipped with a t-structure, we define the left completion $\widehat{\mathcal{C}}$ of $\mathcal{C}$ to be a homotopy limit of the tower

$$
\ldots \to \mathcal{C}_{\leq 2} \xrightarrow{\tau_{\leq 1}} \mathcal{C}_{\leq 1} \xrightarrow{\tau_{\leq 0}} \mathcal{C}_{\leq 0} \xrightarrow{\tau_{\leq -1}} \ldots
$$

Using the results of §T.3.3.3, we can obtain a very concrete description of this inverse limit: it is the full subcategory of $\text{Fun}(\mathbb{N}(\mathbb{Z}), \mathcal{C})$ spanned by those functors $F : \mathbb{N}(\mathbb{Z}) \to \mathcal{C}$ with the following properties:

1. For each $n \in \mathbb{Z}$, $F(n) \in \mathcal{C}_{\leq -n}$.

2. For each $m \leq n \in \mathbb{Z}$, the associated map $F(m) \to F(n)$ induces an equivalence $\tau_{\leq -n}F(m) \to F(n)$.

We will denote this inverse limit by $\widehat{\mathcal{C}}$, and refer to it as the left completion of $\mathcal{C}$.

**Proposition 1.2.1.17.** Let $\mathcal{C}$ be a stable $\infty$-category equipped with a t-structure. Then:

1. The left completion $\widehat{\mathcal{C}}$ is also stable.
(2) Let \( \widehat{\mathcal{C}}_{\leq 0} \) and \( \widehat{\mathcal{C}}_{\geq 0} \) be the full subcategories of \( \widehat{\mathcal{C}} \) spanned by those functors \( F : N(\mathbb{Z}) \to \mathcal{C} \) which factor through \( \mathcal{C}_{\leq 0} \) and \( \mathcal{C}_{\geq 0} \), respectively. Then these subcategories determine a t-structure on \( \widehat{\mathcal{C}} \).

(3) There is a canonical functor \( \mathcal{C} \to \widehat{\mathcal{C}} \). This functor is exact, and induces an equivalence \( \mathcal{C}_{\leq 0} \to \widehat{\mathcal{C}}_{\leq 0} \).

**Proof.** We observe that \( \widehat{\mathcal{C}} \) can be identified with the homotopy inverse limit of the tower

\[
\ldots \to \mathcal{C}_{\leq 0} \xrightarrow{\tau_{\leq 0} \Sigma} \mathcal{C}_{\leq 0} \xrightarrow{\tau_{\leq 0} \Sigma} \mathcal{C}_{\leq 0}.
\]

In other words, \( \widehat{\mathcal{C}}^{op} \) is equivalent to the \( \infty \)-category of spectrum objects \( \text{Sp}(\mathcal{C}_{\leq 0}) \) (see Proposition 1.4.2.24 in §1.4.2), and assertion (1) is a special case of Corollary 1.4.2.17.

We next prove (2). We begin by observing that, if we identify \( \widehat{\mathcal{C}} \) with a full subcategory of \( \text{Fun}(N(\mathbb{Z}), \mathcal{C}) \), then the shift functors on \( \widehat{\mathcal{C}} \) can be defined by the formula

\[
(F[n])(m) = F(m + n)[n].
\]

This proves immediately that \( \widehat{\mathcal{C}}_{\geq 0}[1] \subseteq \widehat{\mathcal{C}}_{\geq 0} \) and \( \widehat{\mathcal{C}}_{\leq 0}[-1] \subseteq \widehat{\mathcal{C}}_{\leq 0} \). Moreover, if \( X \in \widehat{\mathcal{C}}_{\geq 0} \) and \( Y \in \widehat{\mathcal{C}}_{\leq -1} = \widehat{\mathcal{C}}_{\leq 0}[-1] \), then \( \text{Map}_{\mathcal{C}}(X,Y) \) can be identified with a homotopy limit of a tower of spaces

\[
\ldots \to \text{Map}_{\mathcal{C}}(X(n),Y(n)) \to \text{Map}_{\mathcal{C}}(X(n - 1),Y(n - 1)) \to \ldots
\]

Since each of these spaces is contractible, we conclude that \( \text{Map}_{\mathcal{C}}(X,Y) \simeq * \); in particular, \( \text{Ext}_{\mathcal{C}}^0(X,Y) = 0 \).

Finally, we consider an arbitrary \( X \in \widehat{\mathcal{C}} \). Let \( X'' = \tau_{\leq -1} \circ X : N(\mathbb{Z}) \to \mathcal{C} \), and let \( u : X \to X'' \) be the induced map. It is easy to check that \( X'' \in \widehat{\mathcal{C}}_{\leq -1} \) and that \( \text{fib}(u) \in \widehat{\mathcal{C}}_{\geq 0} \). This completes the proof of (2).

To prove (3), we let \( \mathcal{D} \) denote the full subcategory of \( N(\mathbb{Z}) \times \mathcal{C} \) spanned by pairs \( (n,C) \) such that \( C \in \mathcal{C}_{\leq -n} \). Using Proposition T.5.2.7.8, we deduce that the inclusion \( \mathcal{D} \subseteq N(\mathbb{Z}) \times \mathcal{C} \) admits a left adjoint \( L \). The composition

\[
N(\mathbb{Z}) \times \mathcal{C} \xrightarrow{\theta} \mathcal{D} \subseteq N(\mathbb{Z}) \times \mathcal{C} \xrightarrow{\mathcal{C}} \mathcal{C}
\]

can be identified with a functor \( \theta : \mathcal{C} \to \text{Fun}(N(\mathbb{Z}), \mathcal{C}) \) which factors through \( \widehat{\mathcal{C}} \). To prove that \( \theta \) is exact, it suffices to show that \( \theta \) is right exact (Proposition 1.1.4.1). Since the truncation functors \( \tau_{\leq n} : \mathcal{C}_{\leq n+1} \to \mathcal{C}_{\leq n} \) are right exact, finite colimits in \( \widehat{\mathcal{C}} \) are computed pointwise. Consequently, it suffices to prove that each of the compositions

\[
\mathcal{C} \xrightarrow{\theta} \widehat{\mathcal{C}} \xrightarrow{\tau_{\leq n}} \mathcal{C}
\]

is right exact. But this composition can be identified with the functor \( \tau_{\leq n} \).

Finally, we observe that \( \mathcal{C}_{\leq 0} \) can be identified with a homotopy limit of the essentially constant tower

\[
\ldots \to \mathcal{C}_{\leq 0} \xrightarrow{\text{id}} \mathcal{C}_{\leq 0} \xrightarrow{\text{id}} \mathcal{C}_{\leq 0} \xrightarrow{\tau_{\leq -1} \Sigma} \mathcal{C}_{\leq -1} \to \ldots,
\]

and that \( \theta \) induces an identification of this homotopy limit with \( \mathcal{C}_{\leq 0} \).

If \( \mathcal{C} \) is a stable \( \infty \)-category equipped with a t-structure, then we will say that \( \mathcal{C} \) is left complete if the functor \( \mathcal{C} \to \widehat{\mathcal{C}} \) described in Proposition 1.2.1.17 is an equivalence.

**Remark 1.2.1.18.** Let \( \mathcal{C} \) be as in Proposition 1.2.1.17. Then the inclusion \( \mathcal{C}^+ \subseteq \mathcal{C} \) induces an equivalence \( \widehat{\mathcal{C}}^+ \to \widehat{\mathcal{C}} \), and the functor \( \mathcal{C} \to \widehat{\mathcal{C}} \) induces an equivalence \( \mathcal{C}^+ \to \widehat{\mathcal{C}}^+ \). Consequently, the constructions

\[
\mathcal{C} \mapsto \widehat{\mathcal{C}} \quad \mathcal{C} \mapsto \mathcal{C}^+
\]

furnish an equivalence between the theory of left bounded stable \( \infty \)-categories and the theory of left complete stable \( \infty \)-categories.
The following criterion is useful for establishing left completeness.

**Proposition 1.2.1.19.** Let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a t-structure. Suppose that \( \mathcal{C} \) admits countable products, and that \( \mathcal{C}_{\geq 0} \) is stable under countable products. The following conditions are equivalent:

1. The \( \infty \)-category \( \mathcal{C} \) is left complete.
2. The full subcategory \( \mathcal{C}_{\geq \infty} = \bigcap \mathcal{C}_{\geq n} \subseteq \mathcal{C} \) consists only of zero objects of \( \mathcal{C} \).

**Proof.** We first observe every tower of objects \( \ldots \to X_n \to X_{n-1} \to \ldots \) in \( \mathcal{C} \) admits a limit \( \lim_{\leftarrow} \{X_n\} \): we can compute this limit as the fiber of an appropriate map

\[
\prod X_n \to \prod X_n.
\]

Moreover, if each \( X_n \) belongs to \( \mathcal{C}_{\geq 0} \), then \( \lim_{\leftarrow} \{X_n\} \) belongs to \( \mathcal{C}_{\geq -1} \).

The functor \( F : \mathcal{C} \to \hat{\mathcal{C}} \) of Proposition 1.2.1.17 admits a right adjoint \( G \), given by

\[
f \in \hat{\mathcal{C}} \subseteq \text{Fun}(N(\mathbb{Z}), \mathcal{C}) \mapsto \lim_{\leftarrow} (f).
\]

Assertion (1) is equivalent to the statement that the unit and counit maps

\[
\begin{align*}
u : F \circ G &\to \text{id}_{\hat{\mathcal{C}}} \\
v : \text{id}_{\mathcal{C}} &\to G \circ F
\end{align*}
\]

are equivalences. If \( v \) is an equivalence, then any object \( X \in \mathcal{C} \) can be recovered as the limit of the tower \( \{\tau_{\leq n} X\} \). In particular, this implies that \( X = 0 \) if \( X \in \mathcal{C}_{\geq \infty} \), so that (1) \( \Rightarrow \) (2).

Now assume (2); we will prove that \( u \) and \( v \) are both equivalences. To prove that \( u \) is an equivalence, we must show that for every \( f \in \hat{\mathcal{C}} \), the natural map

\[
\theta : \lim_{\leftarrow} (f) \to f(n)
\]

induces an equivalence \( \tau_{\leq n} \lim_{\leftarrow} (f) \to f(n) \). In other words, we must show that the fiber of \( \theta \) belongs to \( \mathcal{C}_{\geq -n+1} \). To prove this, we first observe that \( \theta \) factors as a composition

\[
\lim_{\leftarrow} (f) \xrightarrow{\theta'} f(n-1) \xrightarrow{\theta''} f(n).
\]

The octahedral axiom ((TR4) of Definition 1.1.2.6) implies the existence of a fiber sequence

\[
\text{fib}(\theta') \to \text{fib}(\theta) \to \text{fib}(\theta'').
\]

Since \( \text{fib}(\theta'') \) clearly belongs to \( \mathcal{C}_{\geq -n+1} \), it will suffice to show that \( \text{fib}(\theta') \) belongs to \( \mathcal{C}_{\geq -n+1} \). We observe that \( \text{fib}(\theta') \) can be identified with the limit of a tower \( \{\text{fib}(f(m) \to f(n-1))\}_{m<n} \). It therefore suffices to show that each \( \text{fib}(f(m) \to f(n-1)) \) belongs to \( \mathcal{C}_{\geq -n+2} \), which is clear.

We now prove that \( v \) is an equivalence. Let \( X \) be an object of \( \mathcal{C} \), and \( v_X : X \to (G \circ F)(X) \) the associated map. Since \( u \) is an equivalence of functors, we conclude that \( \tau_{\leq n} (v_X) \) is an equivalence for all \( n \in \mathbb{Z} \). It follows that \( \text{cofib}(v_X) \in \mathcal{C}_{\geq n+1} \) for all \( n \in \mathbb{Z} \). Invoking assumption (2), we conclude that \( \text{cofib}(v_X) \simeq 0 \), so that \( v_X \) is an equivalence as desired.

**Remark 1.2.1.20.** The ideas introduced above can be dualized in an obvious way, so that we can speak of **right completions** and **right completeness** for a stable \( \infty \)-category equipped with a t-structure.
1.2.2 Filtered Objects and Spectral Sequences

Suppose given a sequence of objects
\[ \ldots \to X(-1) \xrightarrow{f^0} X(0) \xrightarrow{f^1} X(1) \to \ldots \]
in a stable \( \infty \)-category \( \mathcal{C} \). Suppose further that \( \mathcal{C} \) is equipped with a t-structure, and that the heart of \( \mathcal{C} \) is equivalent to the nerve of an abelian category \( \mathcal{A} \). In this section, we will construct a spectral sequence taking values in the abelian category \( \mathcal{A} \), with the \( E_1 \)-page described by the formula
\[ E_1^{p,q} = \pi_{p+q} \text{cofib}(f^p) \in \mathcal{A}. \]

Under appropriate hypotheses, we will show that this spectral sequence converges to the homotopy groups of the colimit \( \lim \to X(i) \).

Remark 1.2.2.1. The spectral sequence we construct in this section can be viewed as a generalization of the spectral sequence associated to a filtered chain complex in ordinary homological algebra. We refer the reader to [30] for a gentle account of this spectral sequence, and to [108] for a general introduction to spectral sequences.

Our first step is to construct some auxiliary objects in \( \mathcal{C} \).

Definition 1.2.2.2. Let \( \mathcal{C} \) be a pointed \( \infty \)-category, and let \( I \) be a linearly ordered set. We let \( I[1] \) denote the partially ordered set of pairs of elements \( i \leq j \) of \( I \), where \( (i,j) \leq (i',j') \) if \( i \leq i' \) and \( j \leq j' \). An \( I \)-complex in \( \mathcal{C} \) is a functor \( F : N(I[1]) \to \mathcal{C} \) with the following properties:

1. For each \( i \in I \), \( F(i,i) \) is a zero object of \( \mathcal{C} \).
2. For every \( i \leq j \leq k \), the associated diagram
\[
\begin{array}{ccc}
F(i,j) & \longrightarrow & F(i,k) \\
\downarrow & & \downarrow \\
F(j,j) & \longrightarrow & F(j,k)
\end{array}
\]
is a pushout square in \( \mathcal{C} \).

We let \( \text{Gap}(I, \mathcal{C}) \) denote the full subcategory of \( \text{Fun}(N(I[1]), \mathcal{C}) \) spanned by the \( I \)-complexes in \( \mathcal{C} \).

Remark 1.2.2.3. Let \( F \in \text{Gap}(I, \mathcal{C}) \) be a \( \mathcal{I} \)-complex in a stable \( \infty \)-category \( \mathcal{C} \). For each \( n \in \mathbb{Z} \), the functor \( F \) determines pushout square
\[
\begin{array}{ccc}
F(n-1,n) & \longrightarrow & F(n-1,n+1) \\
\downarrow & & \downarrow \\
0 & \longrightarrow & F(n,n+1)
\end{array}
\]
hence a boundary map \( \delta : F(n,n+1) \to F(n-1,n)[1] \). If we set \( C_n = F(n-1,n)[-n] \), then we obtain a sequence of maps
\[ \ldots \to C_1 \xrightarrow{d_1} C_0 \xrightarrow{d_0} C_{-1} \to \ldots \]
in the homotopy category \( \text{hC} \). The commutative diagram
\[
\begin{array}{ccc}
F(n,n+1) & \longrightarrow & F(n-2,n)[1] \xrightarrow{\delta} F(n-2,n-2)[2] \\
\downarrow \delta & & \downarrow \\
F(n-1,n)[1] & \longrightarrow & F(n-2,n-1)[2]
\end{array}
\]
proves that $d_{n-1} \circ d_n \simeq 0$ (since $F(n-2, n-2) \simeq 0$), so that $(C_*, d_*)$ can be viewed as a chain complex in the triangulated category $\mathcal{C}$. This motivates the terminology of Definition 1.2.2.2.

**Lemma 1.2.2.4.** Let $\mathcal{C}$ be a pointed $\infty$-category which admits pushouts. Let $\mathcal{J} = \mathcal{J}_0 \cup \{-\infty\}$ be a linearly ordered set containing a least element $-\infty$. We regard $\mathcal{J}_0$ as a linearly ordered subset of $\mathcal{J}$ via the embedding $i \mapsto (-\infty, i)$.

Then the restriction map $\text{Gap}(\mathcal{J}, \mathcal{C}) \to \text{Fun}(N(\mathcal{J}_0), \mathcal{C})$ is an equivalence of $\infty$-categories.

**Proof.** Let $\mathcal{J} = \{(i, j) \in \mathcal{J}^1 : (i = -\infty) \lor (i = j)\}$. We now make the following observations:

1. A functor $F : N(\mathcal{J}^1) \to \mathcal{C}$ is a complex if and only if $F$ is a left Kan extension of $F|N(\mathcal{J})$, and $F(i, i)$ is a zero object of $\mathcal{C}$ for all $i \in \mathcal{J}$.

2. Any functor $F_0 : N(\mathcal{J}) \to \mathcal{C}$ admits a left Kan extension to $N(\mathcal{J}^1)$ (use Lemma T.4.3.2.13 and the fact that $\mathcal{C}$ admits pushouts).

3. A functor $F_0 : N(\mathcal{J}) \to \mathcal{C}$ has the property that $F_0(i, i)$ is a zero object, for every $i \in \mathcal{J}$, if and only if $F_0$ is a right Kan extension of $F_0|N(\mathcal{J}_0)$.

4. Any functor $F_0 : N(\mathcal{J}_0) \to \mathcal{C}$ admits a right Kan extension to $N(\mathcal{J})$ (use Lemma T.4.3.2.13 and the fact that $\mathcal{C}$ has a final object).

The desired conclusion now follows immediately from Proposition T.4.3.2.15.

**Remark 1.2.2.5.** Let $\mathcal{C}$ be a pointed $\infty$-category which admits pushouts (for example, a stable $\infty$-category). The assignment

$$[n] \mapsto \text{Gap}([n], \mathcal{C})$$

determines a simplicial object in the category $\mathfrak{X} \mathfrak{a} \mathfrak{n}$ of Kan complexes. We can then define the Waldhausen $K$-theory of $\mathcal{C}$ to be a geometric realization of this bisimplicial set (for example, the associated diagonal simplicial set). In the special case where $\mathcal{A}$ is an $A_\infty$-ring and $\mathcal{C}$ is the smallest stable subcategory of $\text{Mod}_A$ which contains $\mathcal{A}$, this definition recovers the usual $K$-theory of $\mathcal{A}$. We refer the reader to [153] for a related construction.

**Construction 1.2.2.6.** Let $\mathcal{C}$ be a stable $\infty$-category equipped with a $t$-structure, such that the heart of $\mathcal{C}$ is equivalent to the nerve of an abelian category $\mathcal{A}$. Let $X \in \text{Gap}(\mathcal{Z}, \mathcal{C})$. We observe that for every triple of integers $i \leq j \leq k$, there is a long exact sequence

$$\ldots \to \pi_n X(i, j) \to \pi_n X(i, k) \to \pi_n X(j, k) \xrightarrow{\delta} \pi_{n-1} X(i, j) \to \ldots$$

in the abelian category $\mathcal{A}$. For every $p, q \in \mathcal{Z}$ and every $r \geq 1$, we define the object $E_{r}^{p, q} \in \mathcal{A}$ by the formula

$$E_{r}^{p, q} = \text{im}(\pi_{p+q} X(p - r, p) \to \pi_{p+q} X(p - 1, p + r - 1)).$$

There is a differential $d_r : E_{r}^{p, q} \to E_{r-1}^{p, q+r+1}$, uniquely determined by the requirement that the diagram

$$\begin{array}{ccc}
\pi_{p+q} X(p - r, p) & \xrightarrow{\delta} & E_{r}^{p, q} \\
\downarrow{\delta} & & \downarrow{d_r} \\
\pi_{p+q-1} X(p - 2r, p - r) & \xrightarrow{\delta} & E_{r-1}^{p, q+r+1}
\end{array}$$

be commutative.

**Proposition 1.2.2.7.** Let $X \in \text{Gap}(\mathcal{Z}, \mathcal{C})$ be as in Construction 1.2.2.6. Then:
For each \( r \geq 1 \), the composition \( d_r \circ d_r \) is zero.

There are canonical isomorphisms

\[
E_{r+1}^{p,q} \simeq \ker(d_r : E_r^{p,q} \to E_r^{p-r,q+r-1})/\im(d_r : E_r^{p+r,q-r+1} \to E_r^{p,q}).
\]

Consequently, \( \{E_r^{p,q}, d_r\} \) is a spectral sequence (with values in the abelian category \( A \)).

Remark 1.2.2.8. For fixed \( q \in \mathbb{Z} \), the complex \( (E^{p,q}_1, d_1) \) in \( A \) can be obtained from the \( hC \)-valued chain complex \( \mathcal{C}_\ast \) described in Remark 1.2.2.3 by applying the homological functor \( \pi_q \).

Proof. We have a commutative diagram

\[
\begin{array}{ccccccccc}
\pi_{p+q}X(p - r - 1, p) & \pi_{p+q+1}X(p, p + r) & \delta & \pi_{p+q}X(p - r, p) & \delta & \pi_{p+q-1}X(p - 2r, p - r) & \pi_{p+q+1}X(p + r - 1, p + 2r - 1) & \delta & \pi_{p+q}X(p - 1, p + r - 1) & \delta & \pi_{p+q-1}X(p - r - 1, p - 1) & \pi_{p+q}X(p - 1, p + r). \\
E_r^{p+r,q-r+1} & & d_r & E_r^{p,q} & d_r & E_r^{p-r,q+r-1} & \pi_{p+q}X(p - r - 1, p) & \delta & \pi_{p+q}X(p - 1, p + r - 1) & \delta & \pi_{p+q-1}X(p - r - 1, p - 1) & \pi_{p+q}X(p - 1, p + r).
\end{array}
\]

Since the upper left vertical map is an epimorphism, (1) will follow provided that we can show that the composition

\[
\pi_{p+q+1}X(p, p + r) \xrightarrow{\delta} \pi_{p+q}X(p - r, p) \xrightarrow{\delta} \pi_{p+q-1}X(p - 2r, p - r)
\]

is zero. This follows immediately from the commutativity of the diagram

\[
\begin{array}{ccccccc}
X(p, p + r) & \delta & X(p - 2r, p)[1] & \delta & X(p - r, p)[1] & X(p - 2r, p - r)[1] & X(p - 2r, p - r)[2]. \\
0 & \sim & X(p - r, p - r)[1] & \delta & X(p - 2r, p - r)[2].
\end{array}
\]

We next claim that the composite map

\[
\phi : \pi_{p+q}X(p - r - 1, p) \to E_r^{p,q} \xrightarrow{d_2} E_r^{p-r,q+r-1}
\]

is zero. Because \( E_r^{p-r,q+r-1} \to \pi_{p+q-1}X(p - r - 1, p - 1) \) is a monomorphism, this follows from the commu-
so that the canonical map $\pi_{p+q} X(p - r - 1, p)$ we are reduced to showing that $\phi$ is a monomorphism. By symmetry, it will suffice to prove the first assertion. Since $\pi_{p+q} X(p - r, p - r - 1)$ factors through $\pi_{p+q} X(p - r - 1, p - r - 1)$, we conclude that the composition $E_r^{p+q,r+1} \to \pi_{p+q} X(p - r - 1, p - r)$ is zero as well.

Let $Z = \ker(d_r : E_r^{p,q} \to E_r^{p-r,q+r-1})$ and $B = \operatorname{im}(d_r : E_r^{p+q,r-q+1} \to E_r^{p,q})$. The above arguments yield a sequence of morphisms

$$
\pi_{p+q} X(p - r - 1, p) \xrightarrow{\phi} Z \xrightarrow{\phi'} Z/B \xrightarrow{\psi'} E_r^{p,q}/B \xrightarrow{\psi} \pi_{p+q} X(p - 1, p + r).
$$

To complete the proof of (2), it will suffice to show that $\phi' \circ \phi$ is an epimorphism and that $\psi \circ \psi'$ is a monomorphism. By symmetry, it will suffice to prove the first assertion. Since $\phi'$ is evidently an epimorphism, we are reduced to showing that $\phi$ is an epimorphism.

Let $K$ denote the kernel of the composite map

$$
\pi_{p+q} X(p - r, p) \xrightarrow{d_r} E_r^{p,q} \xrightarrow{d_p} E_r^{p-r,q+r-1} \to \pi_{p+q-1} X(p - r - 1, p - 1),
$$

so that the canonical map $K \to Z$ is an epimorphism. Choose a diagram

$$
\begin{array}{ccc}
\pi_{p+q} X(p - r, p - 1) & \xrightarrow{f} & K \\
\downarrow g & & \downarrow f' & \downarrow 0 \\
\pi_{p+q-1} X(p - r - 1, p - r) & \xrightarrow{f} & \pi_{p+q-1} X(p - r - 1, p - 1)
\end{array}
$$

where the square on the left is a pullback. The exactness of the bottom row implies that $f$ is an epimorphism. Let $f'$ denote the composition $\tilde{K} \xrightarrow{\varphi} \pi_{p+q} X(p - r, p - 1) \to \pi_{p+q} X(p - r, p)$. The composition $\tilde{K} \xrightarrow{f'} \pi_{p+q} X(p - r, p) \to \pi_{p+q} X(p - 1, p + r)$ factors through $\pi_{p+q} X(p - 1, p - 1)$, so that the composition $\tilde{K} \xrightarrow{f'} \pi_{p+q} X(p - r, p) \to E_r^{p,q}$ is the zero map. It follows that the composition $\tilde{K} \xrightarrow{f - f'} \pi_{p+q} X(p - r, p) \to Z$.
coincides with the composition \( \widetilde{K} \xrightarrow{f} K \to Z \), and is therefore an epimorphism.

Form a diagram

\[
\begin{array}{ccc}
\widetilde{K} & \xrightarrow{f''} & \widetilde{K} \\
\downarrow & & \downarrow \\
\pi_{p+q}X(p-r-1,p) & \to & \pi_{p+q}X(p-r,p) \to \pi_{n-1}X(p-r-1,p-r)
\end{array}
\]

where the left square is a pullback. Since the bottom line is exact, the map \( f'' \) is an epimorphism, so that the composition

\[
\widetilde{K} \xrightarrow{f''} \widetilde{K} \xrightarrow{f-f'} \pi_{p+q}X(p-r,p) \to Z
\]

is an epimorphism. This map coincides with the composition

\[
\widetilde{K} \to \pi_{p+q}X(p-r-1,p) \xrightarrow{\phi} Z,
\]

so that \( \phi \) is an epimorphism as well.

**Definition 1.2.2.9.** Let \( \mathcal{C} \) be a stable \( \infty \)-category. A filtered object of \( \mathcal{C} \) is a functor \( X : N(\mathbb{Z}) \to \mathcal{C} \).

Suppose that \( \mathcal{C} \) is equipped with a t-structure, and let \( X : N(\mathbb{Z}) \to \mathcal{C} \) be a filtered object of \( \mathcal{C} \). According to Lemma 1.2.2.4, we can extend \( X \) to a complex in \( \text{Gap}(\mathbb{Z} \cup \{-\infty\}, \mathcal{C}) \). Let \( X \) be the associated object of \( \text{Gap}(\mathbb{Z}, \mathcal{C}) \), and let \( \{E_r^{p,q}, d_r\}_{r \geq 1} \) be the spectral sequence described in Construction 1.2.2.6 and Proposition 1.2.2.7. We will refer to \( \{E_r^{p,q}, d_r\}_{r \geq 1} \) as the spectral sequence associated to the filtered object \( X \).

**Remark 1.2.2.10.** In the situation of Definition 1.2.2.9, Lemma 1.2.2.4 implies that \( X \) is determined up to contractible ambiguity by \( X \). It follows that the spectral sequence \( \{E_r^{p,q}, d_r\}_{r \geq 1} \) is independent of the choice of \( X \), up to canonical isomorphism.

**Example 1.2.2.11.** Let \( \mathcal{A} \) be a sufficiently nice abelian category, and let \( \mathcal{C} \) be the derived \( \infty \)-category of \( \mathcal{A} \) (see §1.3.2). Let \( \text{Fun}(N(\mathbb{Z}), \mathcal{C}) \) be the \( \infty \)-category of filtered objects of \( \mathcal{C} \). Then the homotopy category \( \text{hFun}(N(\mathbb{Z}), \mathcal{C}) \) can be identified with the classical filtered derived category of \( \mathcal{A} \), obtained from the category of filtered objects of objects of \( \mathcal{A} \) by inverting all filtered quasi-isomorphisms. In this case, Definition 1.2.2.9 recovers the usual spectral sequence associated to a filtered complex.

Our next goal is to study the convergence of the spectral sequence of Definition 1.2.2.9. We will treat only the simplest case, which will be sufficient for our applications in this book.

**Definition 1.2.2.12.** Let \( \mathcal{C} \) be an \( \infty \)-category. We will say that \( \mathcal{C} \) admits sequential colimits if every diagram \( N(\mathbb{Z}_{\geq 0}) \to \mathcal{C} \) has a colimit in \( \mathcal{C} \).

If \( \mathcal{C} \) is stable and admits sequential colimits, we will say that a t-structure on \( \mathcal{C} \) is compatible with sequential colimits if the full subcategory \( \mathcal{C}_{\geq 0} \) is stable under the colimits of diagrams indexed by \( N(\mathbb{Z}_{\geq 0}) \).

**Remark 1.2.2.13.** Let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a t-structure, so that the heart of \( \mathcal{C} \) is equivalent to (the nerve of) an abelian category \( \mathcal{A} \). Suppose that \( \mathcal{C} \) admits sequential colimits. Then \( \mathcal{C}_{\geq 0} \) admits sequential colimits, so that \( N(\mathcal{A}) \), being a localization of \( \mathcal{C}_{\geq 0} \), also admits sequential colimits. If the t-structure on \( \mathcal{C} \) is compatible with sequential colimits, then the inclusion \( N(\mathcal{A}) \subseteq \mathcal{C} \) and the homological functors \( \{\pi_n : \mathcal{C} \to N(\mathcal{A})\}_{n \in \mathbb{Z}} \) preserve sequential colimits. It follows that sequential colimits in the abelian category \( \mathcal{A} \) are exact: in other words, the colimit of a sequence of monomorphisms in \( \mathcal{A} \) is again a monomorphism.

**Proposition 1.2.2.14.** Let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a t-structure, and let \( X : N(\mathbb{Z}) \to \mathcal{C} \) be a filtered object of \( \mathcal{C} \). Assume that \( \mathcal{C} \) admits sequential colimits, and that the t-structure on \( \mathcal{C} \) is compatible with sequential colimits. Suppose furthermore that \( X(n) \simeq 0 \) for \( n \ll 0 \). Then the associated spectral sequence (Definition 1.2.2.9) converges

\[
E_r^{p,q} \Rightarrow \pi_{p+q} \lim_n(X).
\]
1.2. **STABLE ∞-CATEGORIES AND HOMOLOGICAL ALGEBRA**

**Proof.** Let \( A \) be an abelian category such that the heart of \( \mathcal{C} \) is equivalent to (the nerve of) \( A \). The convergence assertion of the Proposition has the following meaning:

(i) For fixed \( p \) and \( q \), the differentials \( d_r : E^{p,q}_r \to E^{p-r,q+r-1}_r \) vanish for \( r \gg 0 \).

Consequently, for sufficiently large \( r \) we obtain a sequence of epimorphisms

\[
E^{p,q}_r \to E^{p,q}_{r+1} \to E^{p,q}_{r+2} \to \ldots
\]

Let \( E^{p,q}_\infty \) denote the colimit of this sequence (in the abelian category \( A \)).

(ii) Let \( n \in \mathbb{Z} \), and let \( A_n = \pi_n \lim_{\to m} X(m) \). Then there exists a filtration

\[
\ldots \subseteq F^{-1}A_n \subseteq F^0A_n \subseteq F^1A_n \subseteq \ldots
\]

of \( A_n \), with \( F^mA_n \simeq 0 \) for \( m < 0 \), and\( \lim_{\to m} F^mA_n \simeq A_n \).

(iii) For every \( p, q \in \mathbb{Z} \), there exists an isomorphism \( E^{p,q}_\infty \simeq \frac{F^pA_{p+q}}{F^{p-1}A_{p+q}} \) in the abelian category \( A \).

To prove (i), (ii), and (iii), we first extend \( X \) to an object \( \overline{X} \in \text{Gap}(\mathbb{Z} \cup \{-\infty\}, \mathcal{C}) \), so that for each \( n \in \mathbb{Z} \) we have \( X(n) = \overline{X}(-\infty, n) \). Without loss of generality, we may suppose that \( X(n) \simeq \ast \) for \( n < 0 \). This implies that \( \overline{X}(i, j) \simeq \ast \) for \( i, j < 0 \). It follows that \( E^{p-r,q+r-1}_r \), as a quotient \( \pi_{p+q}\overline{X}(p-2r, p-r) \), is zero for \( r > p \). This proves (i).

To satisfy (ii), we set \( F^pA_n = \text{im}(\pi_n X(p) \to \pi_n \lim(X)) \). It is clear that \( F^pA_n \simeq \ast \) for \( p < 0 \), and the isomorphism \( \lim F^pA_n \simeq A_n \) follows from the compatibility of the homological functor \( \pi_n \) with sequential colimits (Remark 1.2.2.13).

To prove (iii), we note that for \( r > p \), the object \( E^{p,q}_r \) can be identified with the image of the map

\[
\pi_{p+q}^\ast \overline{X}(p) \simeq \pi_{p+q}^\ast \overline{X}(p-r, p) \to \pi_{p+q}^\ast \overline{X}(p-1, p+r).
\]

Let \( Y = \lim_{\to m} \overline{X}(p-1, p+r) \). It follows that \( E^{p,q}_\infty \) can be identified with the image of the map \( \pi_{p+q}^\ast \overline{X}(p) \to \pi_{p+q}^\ast Y \). We have a fiber sequence

\[
X(p-1) \to \lim_{\to m}(X) \to Y,
\]

which induces an exact sequence

\[
0 \to F^{p-1}A_{p+q} \to A_{p+q} \xrightarrow{f'} \pi_{p+q}^\ast Y.
\]

We have a commutative triangle

\[
\begin{array}{ccc}
A_{p+q} & \xrightarrow{g} & A_{p+q} \\
\pi_{p+q}^\ast X(p) & \xrightarrow{f} & \pi_{p+q}^\ast Y.
\end{array}
\]

Since the image of \( g \) is \( F^pA_{p+q} \), we obtain canonical isomorphisms

\[
E^{p,q}_\infty \simeq \text{im}(f) \simeq \text{im}(f'\mid F^pA_{p+q}) \simeq \frac{F^pA_{p+q}}{\ker(f')} \simeq \frac{F^pA_{p+q}}{F^{p-1}A_{p+q}}.
\]

This completes the proof.
1.2.3 The Dold-Kan Correspondence

Our goal in this section is to review some classical results in homological algebra: most importantly, the Dold-Kan correspondence, which establishes an equivalence between the category of simplicial objects of an abelian category \( \mathcal{A} \) with the category of nonnegatively graded chain complexes over \( \mathcal{A} \) (Theorem 1.2.3.7). This material will be used in studying an \( \infty \)-categorical version of the Dold-Kan correspondence in §1.2.4, and in our construction of derived \( \infty \)-categories in §1.3.

We begin by reviewing some basic definitions from homological algebra.

**Definition 1.2.3.1.** Let \( \mathcal{A} \) be an additive category. A *chain complex* with values in \( \mathcal{A} \) is a composable sequence of morphisms

\[
\cdots \rightarrow A_2 \xrightarrow{d(2)} A_1 \xrightarrow{d(1)} A_0 \xrightarrow{d(0)} A_{-1} \rightarrow \cdots
\]

in \( \mathcal{A} \) such that \( d(n-1) \circ d(n) = 0 \) for every integer \( n \). The collection of chain complexes with values in \( \mathcal{A} \) is itself an additive category, which we will denote by \( \text{Ch}(\mathcal{A}) \).

For each integer \( n \), we let \( \text{Ch}(\mathcal{A}) \geq n \) denote the full subcategory of \( \text{Ch}(\mathcal{A}) \) spanned by those chain complexes \( A_* \) where \( A_k \simeq 0 \) for \( k < n \). Similarly, we let \( \text{Ch}(\mathcal{A}) \leq n \) denote the full subcategory of \( \text{Ch}(\mathcal{A}) \) spanned by those complexes \( A_* \) such that \( A_k \simeq 0 \) for \( k > n \).

**Remark 1.2.3.2.** Throughout this book, we will always use homological indexing conventions for our chain complexes. In particular, the differential on a chain complex always lowers degrees by 1.

**Remark 1.2.3.3.** Let

\[
\cdots \rightarrow A_2 \xrightarrow{d(2)} A_1 \xrightarrow{d(1)} A_0 \xrightarrow{d(0)} A_{-1} \rightarrow \cdots
\]

be a chain complex with values in an additive category \( \mathcal{A} \). We will typically denote this chain complex by \( (A_*, d) \), where \( A_* \) is the underlying \( \mathbb{Z} \)-graded object of \( \mathcal{A} \) and \( d \) is the map of degree \(-1\) from \( A_* \) to itself given by \( d(n) \) in degree \( n \) (so that \( d^2 = 0 \)). Often we will further abuse notation and simply denote this chain complex by \( A_* \) or simply by \( A \), implicitly assuming that a suitable differential has also been supplied.

**Remark 1.2.3.4.** Let \( \mathcal{A} \) be an abelian category. Then the inclusion \( \text{Ch}(\mathcal{A}) \geq 0 \hookrightarrow \text{Ch}(\mathcal{A}) \) admits a right adjoint, which carries a chain complex

\[
\cdots \rightarrow M_2 \xrightarrow{d(2)} M_1 \xrightarrow{d(1)} M_0 \xrightarrow{d(0)} M_{-1} \rightarrow \cdots
\]

to the truncated chain complex

\[
\cdots \rightarrow M_2 \xrightarrow{d(2)} M_1 \xrightarrow{d(1)} \ker(d(0)) \rightarrow 0 \rightarrow \cdots
\]

We will denote this functor by \( \tau_{\geq 0} : \text{Ch}(\mathcal{A}) \rightarrow \text{Ch}(\mathcal{A}) \geq 0 \). Similarly, the inclusion \( \text{Ch}(\mathcal{A}) \leq 0 \hookrightarrow \text{Ch}(\mathcal{A}) \) admits a left adjoint, which we will denote by \( \tau_{\leq 0} : \text{Ch}(\mathcal{A}) \rightarrow \text{Ch}(\mathcal{A}) \leq 0 \).

**Construction 1.2.3.5.** Let \( \mathcal{A} \) be an additive category and let \( A = (A_*, d) \) be a nonnegatively graded chain complex with values in \( \mathcal{A} \). We define a simplicial object \( \text{DK}_*(A) \) of \( \mathcal{A} \) as follows:

1. For each \( n \geq 0 \), the object \( \text{DK}_n(A) \) is given by the direct sum \( \bigoplus_{\alpha : [n] \rightarrow [k]} A_k \); here the sum is taken over all surjective maps \( [n] \rightarrow [k] \) in \( \Delta \).

2. Let \( \beta : [n'] \rightarrow [n] \) be a morphism in \( \Delta \). The induced map

\[
\beta^* : \text{DK}_n(A) \simeq \bigoplus_{\alpha : [n] \rightarrow [k]} A_k \rightarrow \bigoplus_{\alpha' : [n'] \rightarrow [k']} A_{k'} \simeq \text{DK}_{n'}(A)
\]
is given by the matrix of morphisms \( \{ f_{\alpha, \alpha'} : A_k \to A_{k'} \} \), where the map \( f_{\alpha, \alpha'} \) is the identity if \( k = k' \) and the diagram

\[
\begin{array}{ccc}
[n'] & \xrightarrow{\beta} & [n] \\
\downarrow^{\alpha'} & & \downarrow^{\alpha} \\
[k'] & \xrightarrow{id} & [k]
\end{array}
\]

commutes, the map \( f_{\alpha, \alpha'} \) is given by the differential \( d \) if \( k' = k - 1 \) and the diagram

\[
\begin{array}{ccc}
[n'] & \xrightarrow{} & [n] \\
\downarrow^{\alpha'} & & \downarrow^{\alpha} \\
[k'] & \xrightarrow{} & \{1, \ldots, k\} \\
\end{array}
\]

commutes, and \( f_{\alpha, \alpha'} \) is zero otherwise.

The construction \( A \mapsto \text{DK}_\bullet(A) \) determines a functor from the category \( \text{Ch}(A)_{\geq 0} \) to the category \( \text{Fun}(\Delta^{op}, A) \) of simplicial objects of \( A \). We will denote this functor by \( \text{DK} \), and refer to it as the Dold-Kan construction.

**Example 1.2.3.6.** For every simplicial set \( K_\bullet \), let \( ZK_\bullet \) denote the free simplicial abelian group generated by \( K_\bullet \) (so that \( (ZK)_n \) is the free abelian group generated by the set \( K_n \) for each \( n \geq 0 \)). Let \( Z[n]_\bullet \) denote the chain complex of abelian groups given by

\[
Z[n]_k = \begin{cases}
\mathbb{Z} & \text{if } k = n \\
0 & \text{if } k \neq n.
\end{cases}
\]

Then there is a canonical isomorphism of simplicial abelian groups

\[
\text{DK}_\bullet(Z[n]) \cong \mathbb{Z}\Delta^n / \mathbb{Z} \partial \Delta^n.
\]

Our main goal in this section is to prove the following:

**Theorem 1.2.3.7** (Dold-Kan Correspondence). Let \( A \) be an additive category. The functor

\[
\text{DK} : \text{Ch}(A)_{\geq 0} \to \text{Fun}(\Delta^{op}, A)
\]

is fully faithful. If \( A \) is idempotent complete, then \( A \) is an equivalence of categories.

The proof of Theorem 1.2.3.7 will proceed by reducing to the case where \( A \) is the category of abelian groups. In this case, we can explicitly describe an inverse to the functor \( \text{DK} \): it is given by assigning to each simplicial abelian group \( A_\bullet \) the associated normalized chain complex \( N_\bullet(A) \).

**Definition 1.2.3.8.** Let \( A \) be an additive category and let \( A_\bullet \) be a semisimplicial object of \( A \). Fix \( n > 0 \). For each \( 0 \leq i \leq n \), we let \( d_i : A_n \to A_{n-1} \) denote the associated face map (determined by the unique injective map \( [n-1] \to [n] \) whose image does not contain \( i \in [n] \)). Let \( d(n) : A_n \to A_{n-1} \) denote the alternating sum \( \sum_{0 \leq i \leq n} (-1)^i d_i \). An easy calculation shows that \( d(n-1) \circ d(n) \cong 0 \) for \( n > 0 \), so that

\[
\cdots \to A_2 \xrightarrow{d(2)} A_1 \xrightarrow{d(1)} A_0 \to 0 \to \cdots
\]

is a chain complex with values in \( A \). We will denote this chain complex by \( C_\bullet(A) \), and refer to it as the unnormalized chain complex associated to \( A_\bullet \).

If \( A_\bullet \) is a simplicial object of \( A \), we let \( C_\bullet(A) \) denote the unnormalized chain complex of the underlying semisimplicial object of \( A_\bullet \).
Definition 1.2.3.9. Let \( \mathcal{A} \) be an abelian category, and let \( A_\bullet \) be a simplicial object of \( \mathcal{A} \). For each \( n \geq 0 \), we let \( N_n(A) \) denote the subobject of \( A_n \) given by the intersection \( \bigcap_{1 \leq i \leq n} \ker(d_i) \) (more formally: \( N_n(A) \) is defined to be a kernel of the map \( A_n \to \bigoplus_{1 \leq i \leq n} A_{n-1} \) given by \( \{d_i \}_{1 \leq i \leq n} \)). If \( n > 0 \), the map \( d_0 \) carries \( N_n(A) \) into \( N_{n-1}(A) \); we therefore obtain a chain complex

\[
\cdots \to N_2(A) \to N_1(A) \to N_0(A) \to 0 \to \cdots
\]

which we will denote by \( N_\bullet(A) \). We will refer to \( N_\bullet(A) \) as the normalized chain complex of \( A_\bullet \). The construction \( A_\bullet \mapsto N_\bullet(A) \) determines a functor \( N : \text{Fun}(\Delta^{op}, \mathcal{A}) \to \text{Ch}(\mathcal{A})_{\geq 0} \), which we will refer to as the normalized chain complex functor.

Notation 1.2.3.10. If \( K_\bullet \) is a simplicial set, we define

\[
N_\ast(K) = N_\ast(ZK) \quad C_\ast(K) = C_\ast(ZK),
\]

so that \( N_\ast(K) \subseteq C_\ast(K) \) are chain complexes of abelian groups. By definition, the homology of \( K \) is given by the homology of the chain complex \( C_\ast(K) \) (which is the same as the homology of \( N_\ast(K) \), by Proposition 1.2.3.17).

Remark 1.2.3.11. Let \( \mathcal{A} \) be an abelian category, let \( A = (A_\bullet, d) \) be a nonnegatively graded chain complex with values in \( \mathcal{A} \), and let \( DK_\bullet(A) \) be the associated simplicial object of \( \mathcal{A} \). If \( \alpha : [n] \to [k] \) is a surjective morphism in \( \Delta \) for \( k < n \), then there exists \( 1 \leq i \leq n \) such that the composite map

\[
[n - 1] \xrightarrow{\beta} [n] \xrightarrow{\alpha} [k]
\]

is also surjective; here \( \beta \) denotes the unique injective map whose image does not contain \( i \in [n] \). It follows that the subobject \( N_n(DK(A)) \subseteq DK_n(A) \cong \bigoplus_{\alpha : [n] \to [k]} A_k \) can be identified with the summand \( A_n \) corresponding to the identity map \( \alpha : [n] \to [n] \). The isomorphisms \( N_n(DK(A)) \cong A_n \) are compatible with differentials, giving a canonical isomorphism of chain complexes

\[
A \cong N_\ast(DK(A)).
\]

Lemma 1.2.3.12. Let \( \mathcal{A} \) be an abelian category. The isomorphism of functors \( u : \text{id}_{\text{Ch}_{\geq 0}(\mathcal{A})} \cong N_\ast \circ DK \) constructed in Remark 1.2.3.11 exhibits \( N_\ast \) as a right adjoint to \( DK \).

Proof. Let \( A = (A_\bullet, d) \) be a nonnegatively graded chain complex with values in \( \mathcal{A} \), and let \( B_\bullet \) be a simplicial object of \( \mathcal{A} \). We wish to show that the canonical map

\[
\theta : \text{Hom}_{\text{Fun}(\Delta^{op}, \mathcal{A})}(DK_\bullet(A), B_\bullet) \to \text{Hom}_{\text{Ch}(\mathcal{A})}(N_\ast(DK(A)), N_\ast(B)) \xrightarrow{u} \text{Hom}_{\text{Ch}(\mathcal{A})}(A_\bullet, N_\ast(B))
\]

is bijective. To this end, suppose we are given a morphism \( \phi : A_\bullet \to N_\ast(B) \) in \( \text{Ch}(\mathcal{A}) \), given by a collection of maps \( \phi_n : A_n \to N_n(B) \subseteq B_n \). We define a map \( \Phi_n : DK_n(A) \cong \bigoplus_{\alpha : [n] \to [k]} A_k \to B_n \) to be the sum of the maps \( f_\alpha : A_k \xrightarrow{\alpha} B_k \xrightarrow{\phi_k} B_n \), where \( \alpha^* : B_k \to B_n \) is the map associated to \( \alpha \) by the simplicial object \( B_\bullet \). It is easy to see that the maps \( \Phi_n \) together determine a map of simplicial objects \( \Phi : DK_\bullet(A) \to B_\bullet \), and that \( \Phi \) is the unique preimage of \( \phi \) under \( \theta \). \( \square \)

Lemma 1.2.3.13. Let \( \text{Ab} \) denote the category of abelian groups. Then the functor \( DK : \text{Ch}(\text{Ab})_{\geq 0} \to \text{Fun}(\Delta^{op}, \text{Ab}) \) is an equivalence of categories.

Proof. Let \( N_\ast : \text{Fun}(\Delta^{op}, \text{Ab}) \to \text{Ch}(\text{Ab})_{\geq 0} \) be the normalized chain complex functor (Definition 1.2.3.9), so that \( N_\ast \) is right adjoint to \( DK \) (Lemma 1.2.3.12) and the unit map \( u : \text{id} \to N_\ast \circ DK \) is an isomorphism of functors (Remark 1.2.3.11). It will therefore suffice to show that the counit map \( v : DK \circ N_\ast \to \text{id} \) is an isomorphism of functors. In other words, we must show that for every simplicial abelian group \( A_\bullet \), the canonical map

\[
\theta : DK_\ast(N_\ast(A)) \to A_\ast
\]

is an isomorphism.
1.2. STABLE ∞-CATEGORIES AND HOMOLOGICAL ALGEBRA

is an isomorphism of simplicial abelian groups.

We begin by showing that θ is injective in each degree. Fix \( n \geq 0 \), and let \( x \in \text{DK}_n(N_\bullet(A)) \), so that \( x \) corresponds to a collection of elements \( x_n \in N_k(A) \) indexed by surjective maps \( \alpha : [n] \to [k] \) in \( \Delta \). Assume that \( x \neq 0 \); we wish to prove that \( \theta(x) \neq 0 \). Let \( S \) be the collection consisting of those surjective maps \( \alpha : [n] \to [k] \) such that \( x_\alpha \neq 0 \). Since \( x \neq 0 \), the set \( S \) is nonempty. Let \( k \) be the smallest nonnegative integer such that there exists a map \( \alpha : [n] \to [k] \) in \( S \). Given any such map, we let \( m_\alpha \) be the least element of \( \alpha^{-1} \{i\} \) for \( 0 \leq i \leq k \). Assume that \( \alpha : [n] \to [k] \) has been chosen such that \( x_\alpha \neq 0 \) and the sum \( m_\alpha^0 + \cdots + m_{\alpha}^k \) is as small as possible. The assignment \( i \mapsto m_i^\alpha \) determines a map \( \beta : [k] \to [n] \), which is right inverse to \( \alpha \). We will prove that \( \theta(x) \neq 0 \) by showing that \( \beta^\ast \theta(x) = x_\alpha \in A_k \). To prove this, it will suffice to show that for every surjective map \( \alpha' : [n] \to [k'] \) different from \( \alpha \), we have \( \beta^\ast \alpha'^\ast x_{\alpha'} = 0 \) in \( A_k \). If \( \alpha' \notin S \), then \( x_{\alpha'} = 0 \) and the result is obvious. Assume therefore that \( \alpha' \in S \), and let \( \gamma \) denote the composite map

\[
[k] \xrightarrow{\beta} [n] \xrightarrow{\alpha'} [k'].
\]

Since \( \gamma \) is surjective, we have \( m_\alpha^0 \) so that \( \gamma(0) = 0 \). Since \( x_{\alpha'} \in N_{k'}(A) \), we have \( \gamma^\ast x_{\alpha'} = 0 \) unless the image of \( \gamma \) contains every nonzero element of \( k' \). We may therefore assume that \( \gamma \) is surjective. The minimality of \( k \) implies that \( k' \geq k \), so that \( k = k' \) and \( \gamma \) is the identity map. Thus \( \alpha'(m_\alpha^0) = i \) for 0 \leq i \leq k, so that \( m_\alpha^i \geq m_\alpha^k \). On the other hand, our minimality assumption on \( \alpha \) guarantees that \( m_\alpha^0 + \cdots + m_{\alpha}^k \leq m_\alpha^0 + \cdots + m_{\alpha}^k \). It follows that \( m_\alpha^0 = m_\alpha^i \) for 0 \leq i \leq k, so that \( \alpha = \alpha' \) contrary to our assumption.

We now prove that \( \theta \) induces a surjection \( \theta_n : \text{DK}_n(N_\bullet(A)) \to A_n \) using induction on \( n \). For 0 \leq i \leq n, let \( d_i : A_n \to A_{n-1} \) denote the \( i \)th face map, and let \( A(i)_n = \bigcap_{j \geq i} \ker(d_j) \subseteq A_n \). We will prove by induction on \( i \) that the image of \( \theta_n \) contains \( A(i)_n \). When \( i = 0 \), we have \( A(i)_n = N_n(A) \) and the result is obvious. Assume therefore that \( 0 < i \leq n \), and that the image of \( \theta_n \) contains \( A(i-1)_n \). Let \( x \in A(i)_n \); we wish to prove that \( x \) belongs to the image of \( \theta_n \). Let \( \alpha : [n] \to [n] \) be given by the formula

\[
\alpha(j) = \begin{cases} j & \text{if } j \neq i \\ i-1 & \text{if } j = i, \end{cases}
\]

and let \( x' = \alpha^\ast(x) \in A_n \). Since \( \alpha \) factors through \( [n-1] \), \( x' \) belongs to the image of a degeneracy map \( A_{n-1} \to A_n \) and therefore to the image of \( \theta_n \) (since \( \theta_{n-1} \) is surjective by the inductive hypothesis). It will therefore suffice to show that \( x - x' \) belongs to the image of \( \theta_n \). This follows from the inductive hypothesis, since \( x - x' \in A(i-1)_n \).

**Remark 1.2.3.14.** Let \( A_\bullet \) be a simplicial abelian group. Then the underlying simplicial set of \( A_\bullet \) is a Kan complex with a canonical base point (given by 0 \in \( A_0 \)), so that we can define homotopy sets \( \pi_n(A) \) for each \( n \geq 0 \). The abelian group structure on \( A_\bullet \) determines an abelian group structure on each \( \pi_n(A) \), which agrees with the usual group structure on \( \pi_n(A) \) for \( n > 0 \). Unwinding the definitions, we see that \( \pi_n(A) \) can be identified with the \( n \)th homology group of the normalized chain complex \( N_\bullet(A) \).

**Proof of Theorem 1.2.3.7.** Enlarging the universe if necessary, we may assume that the additive category \( A \) is small. Define \( j : A \to \text{Fun}(A^{op}, Ab) \) by the formula \( j(A)(B) = \text{Hom}_A(B, A) \). We first claim that \( j \) is fully faithful. To prove this, we let \( j' : A \to \text{Fun}(A^{op}, \text{Set}) \) denote the usual Yoneda embedding, so that \( j' \) is given by composing \( j \) with the forgetful functor \( U : Ab \to \text{Set} \). Yoneda’s lemma implies that for any pair of objects \( A, B \in A \), the composite map

\[
\text{Hom}_A(A, B) \xrightarrow{\theta} \text{Hom}_{\text{Fun}(A^{op}, Ab)}(j(A), j(B)) \xrightarrow{\theta'} \text{Hom}_{\text{Fun}(A^{op}, \text{Set})}(j'(A), j'(B))
\]

is bijective. This implies that \( \theta' \) is surjective. Since the functor \( U \) is faithful, the map \( \theta' \) is also injective and therefore an isomorphism. By the two-out-of-three property, we conclude that \( \theta \) is bijective as desired.
Note that \( \mathcal{A}' = \text{Fun}(\mathcal{A}^{\text{op}}, \mathcal{A}) \) is itself an additive category (in fact, an abelian category) and that the functor \( j \) preserves finite sums and products. It follows that the diagram

\[
\begin{array}{ccc}
\text{Ch}(\mathcal{A})_{\geq 0} & \xrightarrow{\text{DK}} & \text{Fun}(\Delta^{\text{op}}, \mathcal{A}) \\
\downarrow & & \downarrow \\
\text{Ch}(\mathcal{A}')_{\geq 0} & \xrightarrow{\text{DK}} & \text{Fun}(\Delta^{\text{op}}, \mathcal{A}')
\end{array}
\]

commutes up to canonical isomorphism. Here the vertical maps are fully faithful embeddings, and Lemma 1.2.3.13 implies that the bottom horizontal map is an equivalence of categories. It follows that \( \text{DK} : \text{Ch}(\mathcal{A})_{\geq 0} \to \text{Fun}(\Delta^{\text{op}}, \mathcal{A}) \) is a fully faithful embedding. Moreover, we obtain the following characterization of its essential image: a simplicial object \( A_* \) of \( \mathcal{A} \) belongs to the essential image of \( \text{DK} \) if and only if the chain complex \( N_* (j(A)) \) belongs to the essential image of the fully faithful embedding \( \text{Ch}(\mathcal{A})_{\geq 0} \to \text{Ch}(\mathcal{A}')_{\geq 0} \). This is equivalent to the requirement that each \( N_n (j(A)) \) belongs to the essential image of \( j \). Note that \( N_n (j(A)) \) is a direct summand of \( \text{DK}_n (N_* (j(A))) \simeq j(A_n) \). If \( \mathcal{A} \) is idempotent complete, it follows automatically that \( N_n (j(A)) \) belongs to the essential image of \( j \), so that \( \text{DK} : \text{Ch}(\mathcal{A})_{\geq 0} \to \text{Fun}(\Delta^{\text{op}}, \mathcal{A}) \) is an equivalence of categories. \( \square \)

**Remark 1.2.3.15.** Let \( \mathcal{A} \) be an idempotent complete additive category. Theorem 1.2.3.7 guarantees that the functor \( \text{DK} : \text{Ch}(\mathcal{A})_{\geq 0} \to \text{Fun}(\Delta^{\text{op}}, \mathcal{A}) \) is an equivalence of categories. We let \( N_* : \text{Fun}(\Delta^{\text{op}}, \mathcal{A}) \to \text{Ch}(\mathcal{A})_{\geq 0} \) denote the normalized chain complex functor. It follows from Lemma 1.2.3.12 that this definition agrees with Definition 1.2.3.9 in the case where \( \mathcal{A} \) is abelian. In fact, we can say more: for each \( n \geq 0 \) and every simplicial object \( A_* \) in \( \mathcal{A} \), the object \( N_n (A) \) can be identified with a kernel of the map \( A_n \to \bigoplus_{1 \leq i \leq n} A_{n-1} \) given by the face maps \( \{d_i\}_{1 \leq i \leq n} \) (note that since \( \mathcal{A} \) is not assumed to be abelian, the existence of this kernel is not immediately obvious). More precisely, we claim that the canonical map \( u_n : N_n (A) \to \text{DK}_n (N_* (A)) \simeq A_n \) induces an injective map \( \text{Hom}_\mathcal{A}(X, N_n (A)) \to \text{Hom}_\mathcal{A}(X, A_n) \), whose image consists of those maps \( \phi : X \to A_n \) such that the composite map \( X \xrightarrow{\phi} A_n \xrightarrow{d_i} A_{n-1} \) is zero for \( 1 \leq i \leq n \). To prove this, we invoke Theorem 1.2.3.7 to reduce to the case where \( A_* = \text{DK}_* (B) \) for some \( B_* \in \text{Ch}(\mathcal{A})_{\geq 0} \), and note that for every surjective map \( \alpha : [n] \to [k] \) which is not an isomorphism, there exists an injective map \( \beta : [n-1] \to [n] \) with \( \beta(0) = 0 \) such that \( \alpha \circ \beta \) is again surjective.

We observe that, as in Definition 1.2.3.9, the maps \( u_n : N_n (A) \to A_n \) determine a monomorphism of chain complexes \( u : N_* (A) \to C_* (A) \).

**Remark 1.2.3.16.** Let \( \mathcal{A} \) be an idempotent complete additive category. If \( A_* \) is a simplicial object of \( \mathcal{A} \) and \( 0 \leq i \leq n-1 \), we let \( s_i : A_{n-1} \to A_n \) denote the \( i \)th degeneracy map: that is, the map obtained from the unique surjective morphism \( \alpha : [n] \to [n-1] \) in \( \Delta \) satisfying \( \alpha(i) = \alpha(i+1) = i \). The normalized chain complex \( N_* (A) \) described in Remark 1.2.3.15 admits a dual description: for each \( n \geq 0 \), the object \( N_n (A) \) can be identified with a cokernel of the map

\[
\bigoplus_{0 \leq i < n} A_{n-1} \to A_n
\]

given by \( \{s_i\}_{0 \leq i < n} \) (note that the existence of this cokernel is not immediately obvious when \( \mathcal{A} \) is not an abelian category). Indeed, Theorem 1.2.3.7 allows us to assume that \( A_* = \text{DK}_* (B) \) for some chain complex \( B_* \in \text{Ch}(\mathcal{A})_{\geq 0} \), in which case the result is obvious. The identifications above give maps \( v_n : A_n \to N_n (A) \) for \( n \geq 0 \), which determine an epimorphism of chain complexes \( v : C_* (A) \to N_* (A) \).

In the situation of Remark 1.2.3.16, it is easy to see that the map \( v : C_* (A) \to N_* (A) \) is a left inverse to the monomorphism \( u : N_* (A) \to C_* (A) \): that is, the composition

\[
N_* (A) \xrightarrow{v} C_* (A) \xrightarrow{u} N_* (A)
\]

is the identity. Though \( u \) and \( v \) are not inverse to one another, one has the following closely related result:
Proposition 1.2.3.17. Let \( A \) be an abelian category and let \( A_\bullet \) be a simplicial object of \( A \). Then the canonical maps

\[
u : N_\ast(A) \to C_\ast(A) \quad \quad \quad v : C_\ast(A) \to N_\ast(A)
\]

are quasi-isomorphisms of chain complexes.

Proof. Since \( u \) is right inverse to \( v \), it will suffice to show that \( v \) is a quasi-isomorphism. This is equivalent to the assertion that the chain complex \( \ker(v) \) is acyclic (since \( v \) is an epimorphism). Using Theorem 1.2.3.7, we may assume that \( A_\bullet = \text{DK}_\bullet(A) \) for some chain complex \( B_\ast \in \text{Ch}(A)_{\geq 0} \). For each \( n \), we have a canonical isomorphism \( C_n(A) \cong \bigoplus_{\alpha : [n] \to [k]} B_k \), where the sum is taken over all surjective maps \( \alpha : [n] \to [k] \). For every integer \( i \), let \( C^\leq_i(A) \) be the subobject of \( C_n(A) \) generated by the summands \( B_k \) such that \( \alpha(j) = \alpha(j - 1) \) for some \( j \) satisfying \( n - i \leq j \leq n \). Then \( C^\leq_i(A) \) is a subcomplex of \( \ker(v) \), which coincides with \( \ker(v) \) in degrees \( \leq i \). It follows that the inclusion \( C^\leq_i(A) \to \ker(v) \) induces an isomorphism on homology in degrees \( \leq i \) and \( i + 1 \). It will therefore suffice to show that each of the chain complexes \( C^\leq_i(A) \) is acyclic. For this, we proceed by induction on \( i \). If \( i < 0 \), then \( C^\leq_i(A) \cong 0 \) and the result is obvious. We may therefore assume that \( i \geq 0 \). We have a short exact sequence of chain complexes

\[
0 \to C^\leq_{i-1}(A) \to C^\leq_i(A) \to K_i \to 0
\]

for some \( K_i \in \text{Ch}(A)_{\geq 0} \). Using the associated long exact sequence together with the inductive hypothesis, we are reduced to proving that the chain complex \( K_i \) is acyclic. To prove this, consider the maps \( \{(-1)^{n-i-1}s_{n-1-i} : A_n \to A_{n+1}\} \). It is not difficult to see that these maps preserve the subcomplexes \( C^\leq_{i-1}(A) \subseteq C^\leq_i(A) \), and therefore determine a map \( h : K_i \to K_{i+1} \). A simple calculation shows that \( dh + hd = \text{id}_{K_i} \), so that \( \text{id}_{K_i} \) is chain homotopic to the zero map and \( K_i \) is acyclic as desired. \( \Box \)

Remark 1.2.3.18. Let \( A \) be an idempotent complete additive category. The restriction functor

\[
\text{Fun}(\Delta_{\ast}^{\text{op}}, A) \to \text{Fun}(\Delta_{\ast}^{\text{op}}, A)
\]

admits a left adjoint \( F \), which carries each semisimplicial object \( A_\bullet \) of \( A \) to the simplicial object \( F(A)_\bullet \), given by left Kan extension along the inclusion \( \Delta_{\ast}^{\text{op}} \to \Delta_{\ast}^{\text{op}} \). Unwinding the definitions, we see that \( F(A)_\bullet \) is described by the formula

\[
F(A)_n = \bigoplus_{\alpha : [n] \to [k]} A_k,
\]

where \( \alpha \) ranges over all surjective maps in \( \Delta \). We observe that for \( k < n \), the corresponding summand of \( F(A)_n \) lies in the image of some degeneracy map \( A_{n-1} \to A_n \). Let \( v : C_\ast(F(A)) \to N_\ast(F(A)) \) be as in Remark 1.2.3.16; we conclude that the composite map

\[
\theta_A : C_\ast(A) \to C_\ast(F(A)) \to N_\ast(F(A))
\]

is an isomorphism in \( \text{Ch}(A)_{\geq 0} \).

Suppose now that \( A_\bullet \) can be extended to a simplicial object of \( A \), which we will denote also by \( A_\bullet \). We then obtain a map of simplicial objects \( F(A)_\bullet \to A_\bullet \), which induces a map of chain complexes \( C_\ast(A) \xrightarrow{\theta_A} N_\ast(F(A)) \to N_\ast(A_\bullet) \), which agrees with the map \( v \) of Remark 1.2.3.16.

We now discuss the behavior of the Dold-Kan correspondence with respect to tensor products.

Definition 1.2.3.19. Suppose we are given additive categories \( A^1, A^2, \ldots, A^n \), and \( B \). We will say that a functor \( F : A^1 \times \cdots \times A^n \to B \) is multi-additive if the functor \( F \) preserves direct sums separately in each variable.
CHAPTER 1. STABLE ∞-CATEGORIES

Remark 1.2.3.20. Let \( F : \mathcal{A}^1 \times \cdots \times \mathcal{A}^n \to \mathcal{B} \) be a multi-additive functor, and suppose we choose objects \( A^1, A^n \in \mathcal{A}^i \) for \( 1 \leq i \leq n \). The induced map
\[
\prod_{1 \leq i \leq n} \text{Hom}_{\mathcal{A}^i}(A^i, A'^i) \to \text{Hom}_{\mathcal{B}}(F\{A^1\}, F\{A'^1\})
\]
is additive in each variable: that is, it induces a map of abelian groups
\[
\bigotimes_{1 \leq i \leq n} \text{Hom}_{\mathcal{A}^i}(A^i, A'^i) \to \text{Hom}_{\mathcal{B}}(F\{A^1\}, F\{A'^1\}).
\]

Remark 1.2.3.21. Let \( F : \mathcal{A}^1 \times \cdots \times \mathcal{A}^n \to \mathcal{B} \) be a multi-additive functor. Then \( F \) induces a multi-additive functor
\[
\text{Ch}(F)_{\geq 0} : \text{Ch}(\mathcal{A}^1)_{\geq 0} \times \cdots \times \text{Ch}(\mathcal{A}^n)_{\geq 0} \to \text{Ch}(\mathcal{B})_{\geq 0},
\]
which is given on objects by the formula
\[
\text{Ch}(F)_{\geq 0}((A^1, d^1), \ldots, (A^n, d^n))_p = \bigoplus_{p = p_1 + \cdots + p_n} F(A^1_{p_1}, \ldots, A^n_{p_n}),
\]
where the differential \( d \) is given on the summand \( F(A^1_{p_1}, \ldots, A^n_{p_n}) \) by the sum
\[
\sum_{1 \leq i \leq n} (-1)^{p_1 + \cdots + p_{i-1}} F(id_{A^1_{p_1}}, \ldots, \text{id}_{A^1_{p_{i-1}}}, d^i, \text{id}_{A^1_{p_{i+1}}}, \ldots, \text{id}_{A^n_{p_n}}).
\]
Note that the direct sum is essentially finite, since the summand corresponding to a decomposition \( p = p_1 + \cdots + p_n \) is zero unless \( p_1, \ldots, p_n \geq 0 \). If the additive category \( \mathcal{B} \) admits countable coproducts, then the same formula defines a multi-additive functor \( \text{Ch}(F) : \text{Ch}(\mathcal{A}^1) \times \cdots \times \text{Ch}(\mathcal{A}^n) \to \text{Ch}(\mathcal{B}) \).

If \( F : \mathcal{A}^1 \times \cdots \times \mathcal{A}^n \to \mathcal{B} \) is a multi-additive functor, then \( F \) induces a functor
\[
\text{Fun}(\Delta^{op}, \mathcal{A}^1) \times \cdots \times \text{Fun}(\Delta^{op}, \mathcal{A}^n) \to \text{Fun}(\Delta^{op}, \mathcal{B}),
\]
given by pointwise composition with \( F \). In what follows, we will abuse notation by denoting this functor also by \( F \).

Construction 1.2.3.22. Let \( F : \mathcal{A}^1 \times \cdots \times \mathcal{A}^n \to \mathcal{B} \) be a multi-additive functor between idempotent complete additive categories. Suppose we are given simplicial objects \( \mathcal{A}^i_* \) of \( \mathcal{A}^i \) for \( 1 \leq i \leq n \). For each \( p \geq 0 \), let
\[
\overline{\text{AW}}_p : F(A^1_{p_1}, \ldots, A^n_{p_n}) \to \text{Ch}(F)_{\geq 0}(C_*(A^1), \ldots, C_*(A^n))_p
\]
be the map given by the sum of the maps
\[
F(\alpha^1_* \cdots \alpha^n_*) : F(A^1_{p_1}, \ldots, A^n_{p_n}) \to F(A^1_{p_1}, \ldots, A^n_{p_n}),
\]
where \( \alpha_i \) denotes the map \( [p_i] \mapsto \{p_1 + \cdots + p_{i-1}, p_1 + \cdots + p_{i-1} + 1, \ldots, p_1 + \cdots + p_{i-1} + p_i\} \to [p] \) in \( \Delta \). Using Remark 1.2.3.16, we deduce the existence of a unique map \( \overline{\text{AW}}_p : N_p F(A^1, \ldots, A^n) \to \text{Ch}(F)_{\geq 0}(N_*(A^1), \ldots, N_*(A^n))_p \) such that the diagram
\[
\begin{array}{ccc}
F(A^1_{p_1}, \ldots, A^n_{p_n}) & \xrightarrow{\overline{\text{AW}}_p} & \text{Ch}(F)_{\geq 0}(C_*(A^1), \ldots, C_*(A^n))_p \\
\downarrow & & \downarrow \\
N_p F(A^1, \ldots, A^n) & \xrightarrow{\overline{\text{AW}}_p} & \text{Ch}(F)_{\geq 0}(N_*(A^1), \ldots, N_*(A^n))_p.
\end{array}
\]
commutes. Both of these maps commute with the differential and determine maps of chain complexes
\[
\overline{\text{AW}} : C_*(F(A^1, \ldots, A^n)) \to \text{Ch}(F)_{\geq 0}(C_*(A^1), \ldots, C_*(A^n))
\]
\[
\text{AW} : N_*(F(A^1, \ldots, A^n)) \to \text{Ch}(F)_{\geq 0}(N_*(A^1), \ldots, N_*(A^n)).
\]
We will refer to these maps as the Alexander-Whitney maps associated to \( F \).
1.2. STABLE ∞-CATEGORIES AND HOMOLOGICAL ALGEBRA

Remark 1.2.3.23. Let \( F : \mathcal{A}^1 \times \cdots \times \mathcal{A}^n \to \mathcal{B} \) be a multi-additive functor between idempotent complete additive categories. The Alexander-Whitney maps associated to \( F \) depend on the choice of ordering of the categories \( \mathcal{A}^1, \ldots, \mathcal{A}^n \).

Remark 1.2.3.24. Let \( F : \mathcal{A}^1 \times \cdots \times \mathcal{A}^n \to \mathcal{B} \) be a multi-additive functor. The Alexander-Whitney maps

\[
\overline{AW} : C_*(F(A^1, \ldots, A^n)) \to \text{Ch}(F)_{\geq 0}(C_*(A^1), \ldots, C_*(A^n))
\]

\[
\overline{AW} : N_*(F(A^1, \ldots, A^n)) \to \text{Ch}(F)_{\geq 0}(N_*(A^1), \ldots, N_*(A^n))
\]

depend functorially on the sequence of simplicial objects \( \{A^i_\bullet \in \text{Fun}(\Delta^{op}, A^i)\}_{1 \leq i \leq n} \), and can therefore be viewed as natural transformations of functors.

Remark 1.2.3.25. Let \( \alpha : \{1, \ldots, n\} \to \{1, \ldots, m\} \) be an order-preserving map, and suppose we are given multi-additive functors

\[
F : \prod_{1 \leq i \leq m} \mathcal{B}^i \to \mathcal{C}
\]

\[
G^i : \prod_{\alpha(j)=i} \mathcal{A}^j \to \mathcal{B}^i
\]

between idempotent complete additive categories, and let \( H \) denote the composite functor

\[
\prod_{1 \leq j \leq n} \mathcal{A}^j \xrightarrow{\prod_{\alpha(j)=i} G^j} \prod_{1 \leq i \leq m} \mathcal{B}^i \xrightarrow{F} \mathcal{C}.
\]

Then \( \text{Ch}(H)_{\geq 0} \) is equivalent to the composition

\[
\prod_{1 \leq j \leq n} \text{Ch}(A^j)_{\geq 0} \xrightarrow{\prod_{\alpha(j)=i} \text{Ch}(G^j)_{\geq 0}} \prod_{1 \leq i \leq m} \text{Ch}(B^i)_{\geq 0} \xrightarrow{\text{Ch}(F)_{\geq 0}} \text{Ch}(\mathcal{C})_{\geq 0}.
\]

Let \( \overline{AW}_F, \overline{AW}_{G^i}, \) and \( \overline{AW}_H \) be the Alexander-Whitney natural transformations associated to \( F, G^i, \) and \( H \) respectively. For any sequence of simplicial objects \( A^i_\bullet \in \text{Fun}(\Delta^{op}, A^i) \), the map

\[
\overline{AW}_H : N_*(H(A^1, \ldots, A^n)) \to \text{Ch}(H)_{\geq 0}(N_*(A^1), \ldots, N_*(A^n))
\]

is given by the composition

\[
N_*(H(A^1, \ldots, A^n)) \xrightarrow{\overline{AW}_F} N_*F(G^1(\{A^j\}_{\alpha(j)=1}), \ldots, G^m(\{A^j\}_{\alpha(j)=m})) \xrightarrow{\text{Ch}(F)_{\geq 0}} N_*\{G^i(\{A^j\}_{\alpha(j)=1})\}_{1 \leq i \leq m} \xrightarrow{\text{Ch}(G^i)_{\geq 0}} N_*(A^i)_{\alpha(j)=i} \xrightarrow{\text{Ch}(H)_{\geq 0}} N_*(A^1, \ldots, A^n).
\]

The analogous assertion is also true at the level of unnormalized chain complexes: the Alexander-Whitney maps \( \overline{AW}_H \) associated to \( H \) can be obtained by composing the Alexander-Whitney maps \( \overline{AW}_F \) and \( \overline{AW}_{G^i} \) associated to \( F \) and \( G^i \), respectively.

Example 1.2.3.26. Let \( \mathcal{A} \) be a monoidal category. Assume that \( \mathcal{A} \) is additive, idempotent complete, and that the tensor product \( \otimes : \mathcal{A} \times \mathcal{A} \to \mathcal{A} \) preserves finite products separately in each variable. Then the category of chain complexes \( \text{Ch}(\mathcal{A})_{\geq 0} \) inherits a monoidal structure (from the construction described in Remark 1.2.3.21). The Alexander-Whitney construction supplies maps

\[
N_*(A_\bullet \otimes B_\bullet) \to N_*(A_\bullet) \otimes N_*(B_\bullet)
\]

\[
C_*(A_\bullet \otimes B_\bullet) \to C_*(A_\bullet) \otimes C_*(B_\bullet).
\]

It follows from Remark 1.2.3.25 that these maps are compatible with the associativity constraints for the tensor product operations on \( \text{Fun}(\Delta^{op}, \mathcal{A}) \) and \( \text{Ch}(\mathcal{A})_{\geq 0} \). In other words, the functors \( N_*, C_* : \text{Fun}(\Delta^{op}, \mathcal{A}) \to \text{Ch}(\mathcal{A})_{\geq 0} \) can be promoted to left-lax monoidal functors, as defined in §T.1.3. It follows that the Dold-Kan equivalence \( \text{DK} : \text{Ch}(\mathcal{A})_{\geq 0} \to \text{Fun}(\Delta^{op}, \mathcal{A}) \) is right-lax monoidal (Definition T.1.3.5).
Example 1.2.3.27. Let Latt denote the category of lattices: that is, the full subcategory of the category of abelian groups spanned by those abelian groups which are isomorphic to \( \mathbb{Z}^n \) for some \( n \geq 0 \). For any additive category \( \mathcal{A} \), there is an essentially unique multi-additive functor \( \otimes : \text{Latt} \times \mathcal{A} \to \mathcal{A} \), which is given on objects by \( \mathbb{Z}^n \otimes A \simeq A^n \). If \( \mathcal{A} \) is idempotent complete, the Alexander-Whitney construction determines a map

\[
N_*(L \otimes A) \to N_*(L) \otimes N_*(A),
\]

for any simplicial objects \( L_\bullet \) and \( A_\bullet \) in Latt and \( \mathcal{A} \), respectively. It follows from Remark 1.2.3.25 that if \( L'_\bullet \) is another simplicial object of Latt, then the diagram

\[
\begin{align*}
N_*(L' \otimes L \otimes A) & \to N_*(L') \otimes N_*(L \otimes A) \\
\downarrow & \\
N_*(L' \otimes L) \otimes N_*(A) & \to N_*(L') \otimes N_*(L) \otimes N_*(A)
\end{align*}
\]

is commutative.

Proposition 1.2.3.28. Let \( F : \mathcal{A}^1 \times \ldots \times \mathcal{A}^n \to \mathcal{B} \) be a multi-additive functor between idempotent complete additive categories, and assume that \( \mathcal{B} \) is abelian. For every collection of simplicial objects \( A_\bullet \) of \( \mathcal{A}^i \), the Alexander-Whitney maps

\[
\text{AW} : N_*(F(A^1, \ldots, A^n)) \to \text{Ch}(F)_{\geq 0}(N_*(A^1), \ldots, N_*(A^n))
\]

are quasi-isomorphisms.

Proof. Assume that \( n > 0 \) (otherwise the result is obvious) and fix \( m \geq 0 \); we will show that AW induces an isomorphism on homology in degrees \( \leq m \). Using Theorem 1.2.3.7, we can assume that \( A_\bullet = \text{DK}_*(X^i) \), where \( X^i_\bullet \) is a chain complex in \( \mathcal{A}^i \) for \( 1 \leq i \leq n \). For \( k \in \mathbb{Z} \), let \( X(k)^i \) denote the quotient chain complex of \( X^i_j \), given by

\[
X(k)^i_j = \begin{cases} 
X^i_j & \text{if } j \leq i \\
0 & \text{otherwise.}
\end{cases}
\]

We have commutative diagrams

\[
\begin{align*}
N_*(F(\text{DK}(X^1), \ldots, \text{DK}(X^n))) & \xrightarrow{\text{AW}} \text{Ch}(F)_{\geq 0}(X^1, \ldots, X^n) \\
\downarrow & \\
N_*(F(\text{DK}(X(k)^1), \text{DK}(X^2), \ldots, \text{DK}(X^n))) & \to \text{Ch}(F)_{\geq 0}(X(k)^1, X^2, \ldots, X^n)
\end{align*}
\]

where the vertical maps are isomorphisms in degrees \( \leq k \). It will therefore suffice to show that the lower horizontal map is a quasi-isomorphism for some \( k \geq m \). We prove that the bottom horizontal map is a quasi-isomorphism for all \( k \), using induction on \( k \). If \( k < 0 \), then both sides vanish and there is nothing to prove. If \( k \geq 0 \), then the inductive hypothesis allows us to reduce to proving Proposition 1.2.3.28 after replacing \( X^i_\bullet \) by \( X(k)^i_\bullet \). In other words, we may assume that the chain complex \( X^i_\bullet = M^i[p] \) consists of a single object \( M^i \in \mathcal{A}^i \), concentrated in degree \( p_i = k \). Using the same argument, we may assume that each \( X^i_\bullet \simeq M^i[p_i] \) for some \( M^i \in \mathcal{A}^i \), \( p_i \geq 0 \). Then \( \text{Ch}(F)_{\geq 0}(X^1, \ldots, X^n) \simeq F(M^1, \ldots, M^n)[p] \), where \( p = p_1 + \ldots + p_n \).

Let us view \( \mathcal{B} \) as tensored over the category of lattices Latt, as in Example 1.2.3.27. A mild variant of Example 1.2.3.6 shows that the simplicial object \( F(\text{DK}(X^1), \ldots, \text{DK}(X^n)) \) can be identified with \( F(\{\mathbb{Z} \Delta^i / \partial \Delta^i \otimes M^i\}) \simeq \mathbb{Z}[\prod \Delta^i] / \mathbb{Z}[\partial \prod \Delta^i] \otimes F(M^1, \ldots, M^n) \). Let \( K = \prod_{1 \leq i \leq n} \Delta^i \) and let \( \partial K \) denote the simplicial subset of \( K \) consisting of those simplices \( \sigma \) such that for some \( 1 \leq i \leq n \), the composite
1.2. STABLE ∞-CATEGORIES AND HOMOLOGICAL ALGEBRA

map \sigma \to K \to \Delta^{p_i} is not surjective. Unwinding the definitions, we see that the Alexander-Whitney map AW is obtained by tensoring \( F(M^1, \ldots, M^n) \in \mathcal{B} \) with a map

\[ \theta : N_*(K)/N_*(\partial K) \to \mathbb{Z}[p] \]

of chain complexes of abelian groups. It will therefore suffice to show that \( \theta \) admits a chain homotopy inverse. Since the domain and codomain of \( \theta \) are finite chain complexes of free abelian groups, it will suffice to show that \( \theta \) is a quasi-isomorphism. In other words, we must show that the relative homology \( H_q(K, \partial K) \) vanishes for \( q \neq p \), and that \( \theta \) induces an isomorphism \( H_p(K, \partial K) \cong \mathbb{Z} \). This follows from a straightforward calculation.

1.2.4 The ∞-Categorical Dold-Kan Correspondence

Let \( A \) be an abelian category. Then the classical Dold-Kan correspondence (see [160]) asserts that the category \( \text{Fun}(\Delta^{op}, A) \) of simplicial objects of \( A \) is equivalent to the category \( \text{Ch}_{\geq 0}(A) \) of (homologically) nonnegatively graded chain complexes

\[ \ldots \xrightarrow{d_i} A_1 \xrightarrow{d_0} A_0 \to 0. \]

In this section, we will prove an analogue of this result when the abelian category \( A \) is replaced by a stable ∞-category.

We begin by observing that if \( X_\bullet \) is a simplicial object in a stable ∞-category \( \mathcal{C} \), then \( X_\bullet \) determines a simplicial object of the homotopy category \( h\mathcal{C} \). The category \( h\mathcal{C} \) is not abelian, but it is additive and has the following additional property (which follows easily from the fact that \( h\mathcal{C} \) admits a triangulated structure):

(\ast) If \( i : X \to Y \) is a morphism in \( h\mathcal{C} \) which admits a left inverse, then there is an isomorphism \( Y \cong X \oplus X' \) such that \( i \) is identified with the map \((\text{id}, 0)\).

These conditions are sufficient to construct a Dold-Kan correspondence in \( h\mathcal{C} \). Consequently, every simplicial object \( X_\bullet \) of \( \mathcal{C} \) determines a chain complex

\[ \ldots \to C_1 \to C_0 \to 0 \]

in the homotopy category \( h\mathcal{C} \). In §1.2.2, we saw another construction which gives rise to the same type of data. Namely, Lemma 1.2.2.4 and Remark 1.2.2.3 show that every \( \mathbb{Z}_{\geq 0} \)-filtered object

\[ Y(0) \xrightarrow{f_1} Y(1) \xrightarrow{f_2} \ldots \]

determines a chain complex \( C_\bullet \) with values in \( h\mathcal{C} \), where \( C_n = \text{cofib}(f_n)[-n] \). Thus, every \( \mathbb{Z}_{\geq 0} \)-filtered object of \( \mathcal{C} \) determines a simplicial object of the homotopy category \( h\mathcal{C} \). Our goal in this section is to prove the following more precise result, whose proof will be given at the end of this section:

**Theorem 1.2.4.1 (∞-Categorical Dold-Kan Correspondence).** Let \( \mathcal{C} \) be a stable ∞-category. Then the ∞-categories \( \text{Fun}(N(\mathbb{Z}_{\geq 0}), \mathcal{C}) \) and \( \text{Fun}(N(\Delta)^{op}, \mathcal{C}) \) are (canonically) equivalent to one another.

**Remark 1.2.4.2.** Let \( \mathcal{C} \) be a stable ∞-category. We may informally describe the equivalence of Theorem 1.2.4.1 as follows. To a simplicial object \( X_\bullet \) of \( \mathcal{C} \), we assign the filtered object

\[ D(0) \to D(1) \to D(2) \to \ldots \]

where \( D(k) \) is the colimit of the \( k \)-skeleton of \( X_\bullet \). In particular, the colimit \( \lim D(j) \) can be identified with geometric realizations of the simplicial object \( X_\bullet \).
Remark 1.2.4.3. Let \( \mathcal{C} \) be a stable \( \infty \)-category, and let \( X \) be a simplicial object of \( \mathcal{C} \). Using the Dold-Kan correspondence, we can associate to \( X \) a chain complex

\[ \ldots \rightarrow C_2 \rightarrow C_1 \rightarrow C_0 \rightarrow 0 \]

in the triangulated category \( \mathsf{hC} \). More precisely, for each \( n \geq 0 \), let \( L_n \in \mathcal{C} \) denote the \( n \)-th latching object of \( X \) (see §T.A.2.9), so that \( X \) determines a canonical map \( \alpha : L_n \rightarrow X_n \). Then \( C_n \simeq \text{cofib}(\alpha) \), where the cofiber can be formed either in the \( \infty \)-category \( \mathcal{C} \) or in its homotopy category \( \mathsf{hC} \) (since \( L_n \) is actually a direct summand of \( X_n \)).

Using Theorem 1.2.4.1, we can also associate to \( X \) a filtered object

\[ D(0) \rightarrow D(1) \rightarrow D(2) \rightarrow \ldots \]

of \( \mathcal{C} \). Using Lemma 1.2.2.4 and Remark 1.2.2.3, we can associate to this filtered object another chain complex

\[ \ldots \rightarrow C'_1 \rightarrow C'_0 \rightarrow 0 \]

with values in \( \mathsf{hC} \). For each \( n \geq 0 \), let \( X(n) \) denote the restriction of \( X \) to \( N(\Delta^n_{\leq 0}) \), and let \( X'(n) \) be a left Kan extension of \( X(n-1) \) to \( N(\Delta^n_{\leq 0}) \). Then we have a canonical map \( \beta : X'(n) \rightarrow X(n) \), which induces an equivalence \( X'(n)_m \rightarrow X(n)_m \) for \( m < n \), while \( X'(n)_n \) can be identified with the latching object \( L_n \). Let \( X''(n) = \text{cofib}(\beta) \). Then \( X''(n)_m = 0 \) for \( m < n \), while \( X''(n)_n \simeq C_n \). Corollary 1.2.4.18 determines a canonical isomorphism \( \lim\limits_{\to} X''(n) \simeq C_n[n] \) in the homotopy category \( \mathsf{hC} \). The map \( D(n-1) \rightarrow D(n) \) can be identified with the composition

\[ D(n-1) \simeq \lim\limits_{\to} X(n-1) \simeq \lim\limits_{\to} X'(n) \rightarrow \lim\limits_{\to} X(n) \simeq D(n). \]

It follows that \( C'_n \simeq \text{cofib}(D(n-1) \rightarrow D(n))[n] \simeq X''(n)[n] \) is canonically isomorphic to \( C_n \). It is not difficult to show that these isomorphisms are compatible with the differentials, so that we obtain an isomorphism of chain complexes \( C_* \simeq C'_* \) with values in the triangulated category \( \mathsf{hC} \).

Remark 1.2.4.4. Let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a t-structure, whose heart is equivalent to (the nerve of) an abelian category \( \mathcal{A} \). Let \( X_* \) be a simplicial object of \( \mathcal{C} \), and let

\[ D(0) \rightarrow D(1) \rightarrow D(2) \rightarrow \ldots \]

be the associated filtered object (Theorem 1.2.4.1). Using Definition 1.2.2.9 (and Lemma 1.2.2.4), we can associate to this filtered object a spectral sequence \( \{E_r^{pq}, d_r\}_{r \geq 1} \) in the abelian category \( \mathcal{A} \). In view of Remarks 1.2.2.8 and 1.2.4.3, for each \( q \in \mathbb{Z} \) we can identify the complex \( (E_1^{*,q}, d_1) \) with the normalized chain complex associated to the simplicial object \( \pi_q X_* \) of \( \mathcal{A} \).

In the situation of Remark 1.2.4.4, suppose that the \( \infty \)-category \( \mathcal{C} \) admits small colimits and that the t-structure on \( \mathcal{C} \) is compatible with filtered colimits, so that the geometric realization \( |X_*| \simeq \lim D(n) \in \mathcal{C} \) is defined. Proposition 1.2.2.14 implies that the spectral sequence converges to a filtration on the homotopy groups \( \pi_{p+q} \lim D(n) \simeq \pi_{p+q}|X_*| \). If we assume that \( X_* \) is a simplicial object of \( \mathcal{C}_{\geq 0} \), then we get a much stronger notion of convergence (which requires weaker assumptions on \( \mathcal{C} \)):

Proposition 1.2.4.5. Let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a t-structure whose heart is equivalent to the nerve of an abelian category \( \mathcal{A} \). Let \( X_* \) be a simplicial object of \( \mathcal{C}_{\geq 0} \), let \( D(0) \rightarrow D(1) \rightarrow D(2) \rightarrow \ldots \) be the associated filtered object of \( \mathcal{C} \) (Theorem 1.2.4.1), and let \( \{E_r^{pq}, d_r\}_{r \geq 1} \) be the associated spectral sequence in \( \mathcal{A} \). Then:

1. The objects \( E_1^{pq} \in \mathcal{A} \) vanish unless \( p, q \geq 0 \).
2. For each \( r \geq 1 \), the objects \( E_r^{pq} \) vanish unless \( p, q \geq 0 \).
(3) Fix $p,q \geq 0$. For $r > p,q + 1$, we have canonical isomorphisms

$$E^p,q_r \simeq E^p,q_{r+1} \simeq E^p,q_{r+2} \simeq \cdots$$

in the abelian category $A$. We let $E^p,q_{\infty} \in A$ denote the colimit of this sequence of isomorphisms, so that $E^p,q_{r'} = E^p,q_r$ for all $r' \geq r$.

(4) For $0 \leq m \leq n$, we have

$$\text{cofib}(D(m) \to D(n)) \in C_{\geq m+1}.$$

(5) Fix an integer $n$. The map $\pi_n D(k) \to \pi_n D(k+1)$ is an epimorphism for $k = n$ and an isomorphism for $k > n$. In particular, we have isomorphisms

$$\pi_n D(n+1) \simeq \pi_n D(n+2) \simeq \cdots$$

We let $A_n$ denote the colimit of this sequence of isomorphisms, so that we have isomorphisms $A_n \simeq \pi_n D(k)$ for $k > n$.

(6) For each integer $n \geq 0$, the object $A_n \in A$ admits a finite filtration

$$0 = F^{-1}A_n \subseteq F^0A_n \subseteq \cdots \subseteq F^nA_n = A_n,$$

where $F^pA_n$ is the image of the map $\pi_n D(p) \to \pi_n D(n+1) \simeq A_n$. We have canonical isomorphisms $F^pA_{p+q}/F^{p-1}A_{p+q} \simeq E^p,q_{\infty}$.

(7) Suppose either that $C$ admits countable colimits, or that $C$ is left complete. Then the simplicial object $X_\bullet$ of $C$ has a geometric realization $X \in C_{\geq 0}$. Moreover, we have canonical isomorphisms $\pi_n X \simeq A_n$ in the abelian category $A$.

Before giving the proof, we need a brief digression.

**Lemma 1.2.4.6.** Let $C$ be a stable $\infty$-category. The following conditions are equivalent:

(1) The $\infty$-category $C$ is idempotent complete.

(2) The homotopy category $hC$ is idempotent complete.

**Proof.** We first show that (2) $\Rightarrow$ (1). Assume that $hC$ is idempotent complete, and suppose that we are given an idempotent $\rho : \text{Idem} \to C$ (where $\text{Idem}$ denotes the $\infty$-category of Definition T.4.4.5.2), which determines an object $X \in C$ and a map $e : X \to X$ such that $e^2$ is homotopic to $e$. We wish to show that $\rho$ has a colimit in $C$. Choosing a cofinal map $N(\mathbb{Z}_{\geq 0}) \to \text{Idem}$, we are reduced to showing that the diagram $\sigma :$

$$X \xrightarrow{e} X \xrightarrow{e} \cdots$$

has a colimit in $C$. Since $e$ is idempotent in the homotopy category, so that assumption (2) implies that we can write $X$ as a direct sum $X' \oplus X''$, where $e$ is given by composing the projection map $X \to X'$ with the inclusion $X' \to X$. In this case, we can write $\sigma$ as a direct sum of diagrams

$$X' \xrightarrow{\text{id}} X' \xrightarrow{\text{id}} X' \to \cdots$$

$$X'' \xrightarrow{0} X'' \xrightarrow{0} X'' \to \cdots,$$

each of which has a colimit in $C$.

We now show that (1) $\Rightarrow$ (2). Without loss of generality, we may assume that $C$ is given as a full stable subcategory of a stable $\infty$-category $D$ which admits sequential colimits (for example, if $C$ is small, we can take $D = \text{Ind}(C)$; see Proposition 1.1.3.6). Let $e : X \to X$ be a morphism in $C$ which is idempotent in the
homotopy category \( h\mathcal{C} \) (so that \( e^2 \) is homotopic to \( e \)). Let \( X' \) denote the colimit (formed in the \( \infty \)-category \( \mathcal{D} \)) of the sequence

\[ X \xrightarrow{e} X \xrightarrow{e} X \xrightarrow{e} \cdots . \]

For any object \( Y \in \mathcal{D} \), composition with \( e \) induces an idempotent map from the abelian group \( \text{Ext}^\ast_{\mathcal{D}}(X, Y) \) to itself. We may therefore write \( \text{Ext}^\ast_{\mathcal{D}}(X, Y) \) as a direct sum \( \text{Ext}^\ast_{\mathcal{D}}(X, Y)^+ \oplus \text{Ext}^\ast_{\mathcal{D}}(X, Y)^- \), where composition with \( e \) induces the identity map on \( \text{Ext}^\ast_{\mathcal{D}}(X, Y)^+ \) and vanishes on \( \text{Ext}^\ast_{\mathcal{D}}(X, Y)^- \). In particular, the tower of abelian groups

\[ \cdots \xrightarrow{e} \text{Ext}^\ast_{\mathcal{D}}(X, Y) \xrightarrow{e} \text{Ext}^\ast_{\mathcal{D}}(X, Y) \xrightarrow{e} \cdots \]

splits as a direct sum of towers

\[ \cdots \xrightarrow{0} \text{Ext}^\ast_{\mathcal{D}}(X, Y)_- \xrightarrow{0} \text{Ext}^\ast_{\mathcal{D}}(X, Y)_- \xrightarrow{0} \cdots \]

so that we have isomorphisms

\[ \varprojlim \text{Ext}^\ast_{\mathcal{D}}(X, Y) \simeq \text{Ext}^\ast_{\mathcal{D}}(X, Y)^+ \quad \text{and} \quad \varprojlim \text{Ext}^\ast_{\mathcal{D}}(X, Y) \simeq 0. \]

It follows that composition with the canonical map \( X \to X' \) induces an isomorphism from \( \text{Ext}^\ast_{\mathcal{D}}(X', Y) \) to the subgroup \( \text{Ext}^\ast_{\mathcal{D}}(X', Y)^+ \subseteq \text{Ext}^\ast_{\mathcal{D}}(X, Y) \). A similar calculation gives \( \text{Ext}^\ast_{\mathcal{D}}(X'', Y) \simeq \text{Ext}^\ast_{\mathcal{D}}(X, Y)_- \), where \( X'' \) denotes the colimit of the sequence

\[ X \xrightarrow{1-e} X \xrightarrow{1-e} X \xrightarrow{1-e} \cdots . \]

In particular, we see that for each object \( Y \in \mathcal{D} \), the natural map \( f : X \to X' \oplus X'' \) induces an isomorphism

\[ \text{Ext}^\ast_{\mathcal{D}}(X', Y) \oplus \text{Ext}^\ast_{\mathcal{D}}(X'', Y) \to \text{Ext}^\ast_{\mathcal{D}}(X, Y), \]

so that \( f \) is an equivalence. In particular, \( X', X'' \in \mathcal{D} \) are retracts of \( X \). Since \( \mathcal{C} \) is idempotent complete, we may assume without loss of generality that \( X' \) and \( X'' \) belong to \( \mathcal{C} \), so that \( e \) determines a splitting \( X \simeq X' \oplus X'' \) in the homotopy category \( h\mathcal{C} \).

\textbf{Remark 1.2.4.7.} Let \( \mathcal{C} \) be a stable \( \infty \)-category, let \( X_\bullet \) be a simplicial object of \( \mathcal{C} \), let

\[ D(0) \to D(1) \to \cdots \]

be the associated filtered object. Let \( \mathcal{C}^\vee \) denote the idempotent completion of \( \mathcal{C} \). It follows from Lemma 1.2.4.6 that the homotopy category \( h\mathcal{C} \) is an idempotent complete additive category. We may therefore apply Theorem 1.2.4.1 to conclude that each \( X_n \) can be written as a finite coproduct of objects of the form \( \Sigma^{-m} \text{cofib}(D(m-1) \to D(m)) \), where \( 0 \leq m \leq n \) (here \( D(-1) \simeq 0 \) by convention).

\textbf{Warning 1.2.4.8.} The proof of Lemma 1.2.4.6 shows that if an \( \infty \)-category \( \mathcal{C} \) is stable, then any idempotent in the homotopy category \( h\mathcal{C} \) can be lifted to an idempotent in the \( \infty \)-category \( \mathcal{C} \). The analogous statement is not true for a general \( \infty \)-category: for example, it is not true in the \( \infty \)-category \( \mathcal{S} \) of spaces. To see this, let \( G \) denote the group of homeomorphism of the unit interval \( [0, 1] \) which fix its endpoints (which we regard as a discrete group), and let \( \lambda : G \to G \) denote the group homomorphism given by the formula

\[ \lambda(g)(t) = \begin{cases} \frac{1}{2}g(2t) & \text{if } 0 \leq t \leq \frac{1}{2} \\ t & \text{if } \frac{1}{2} \leq t \leq 1 \end{cases} \]

Choose an element \( h \in G \) such that \( h(t) = 2t \) for \( 0 \leq t \leq \frac{1}{4} \). Then \( \lambda(g) \circ h = h \circ \lambda(g) \) for each \( g \in G \), so that the group homomorphisms \( \lambda, \lambda^2 : G \to G \) are conjugate to one another. It follows that the induced
map of classifying spaces $e : BG \to BG$ is homotopic to $e^2$, and is therefore idempotent in the homotopy category of spaces. However, we claim that $e$ cannot be lifted to an idempotent in the $\infty$-category of spaces. Otherwise, the natural map from $BG$ to the colimit of the sequence

$$BG \xrightarrow{e} BG \xrightarrow{e} BG \xrightarrow{e} \cdots$$

would admit a left homotopy inverse. Passing to fundamental groups, it would follow that $G$ surjects onto the colimit of the sequence

$$G \xrightarrow{\lambda} G \xrightarrow{\lambda} \cdots.$$

This is clearly impossible, since the homomorphism $\lambda$ is injective but not bijective.

Proof of Proposition 1.2.4.5. To prove (1), we observe that $E_1^{p,q}$ is the $p$th term of the normalized chain complex associated to the simplicial object $\pi_\bullet X$ in $\mathcal{A}$. This homotopy group vanishes for $p < 0$ because the chain complex is nonnegatively graded and for $q < 0$ because we have assumed that each $X_i$ belongs to $\mathcal{C}_{\geq 0}$. Assertion (2) follows immediately from (1) using induction on $r$, since $E_{p+1}^{r,q}$ can be identified with the homology of the complex

$$E_p^{r+q-r-1} \xrightarrow{d} E_p^{r,q} \xrightarrow{d} E_p^{r-q+r-1}.$$  

If $r > p$ and $r > q+1$, then assertion (2) implies that the outer terms vanish, so that we have isomorphisms $E_{p,q} \simeq E_{p+1}^{r,q}$ which proves (3). Note that Remark 1.2.4.7 shows that $\operatorname{cofib}(D(m) \to D(m+1)) \in \mathcal{C}_{\geq m+1}$ for each $m \geq 0$. This proves (4) in the case $n = m+1$; the general case follows by induction on $n-m$. Assertion (5) follows immediately from (4). If we define $F^p A_n$ to be the image of the map $\pi_n D(p) \to \pi_n D(n+1) \simeq A_n$, then we clearly have inclusions

$$\cdots \subseteq F^{-1} A_n \subseteq F^0 A_n \subseteq \cdots \subseteq F^n A_n \subseteq F^{n+1} A_n \subseteq \cdots$$

Since $D(p) \simeq 0$ for $p < 0$, we deduce that $F^p A_n = 0$ for $p < 0$. Similarly, the surjectivity of the map $\pi_n D(n) \to \pi_n D(n+1)$ shows that $F^n A_n = A_n$. To complete the proof of (6), we note that $E_{\infty}^{p,q}$ can be described as the image of the morphism

$$\theta : \pi_{p+q} \operatorname{cofib}(D(p-r) \to D(p)) \to \pi_{p+q} \operatorname{cofib}(D(p-1) \to D(p+r-1))$$

for $r \gg 0$. If $r > p + q + 1$, then $D(p-r) \simeq 0$ and $D(p+r-1) \simeq A_{p+q}$, and we can describe $E_{p,q}^{p,q}$ as the image of $\pi_{p+q} D(p)$ in the quotient $\operatorname{coker}(\pi_{p+q} D(p-1) \to A_{p+q}) \simeq A_{p+q}/F_{p-q} A_{p+q}$, which is isomorphic to the quotient $F^p A_{p+q}/F^{p-1} A_{p+q}$.

It remains to prove (7). Assume first that $\mathcal{C}$ admits countable colimits. Then the existence of $X \simeq |X_\bullet| \simeq \lim_{\rightarrow} D(n)$ is obvious. Moreover, for each $m \geq 0$, we deduce that

$$\operatorname{cofib}(D(m) \to X) \simeq \lim_{\rightarrow} \operatorname{cofib}(D(m) \to D(n)) \in \mathcal{C}_{\geq m+1}$$

(using (4)), so that $\pi_k X \simeq \pi_k D(m) \simeq A_k$ for $k < m$. If we assume instead that $\mathcal{C}$ is left complete, then we must work a bit harder. We first show that the sequence

$$D(0) \to D(1) \to D(2) \to \cdots$$

has a colimit in $\mathcal{C}$. Since $\mathcal{C}$ is a homotopy limit of the tower of $\infty$-categories

$$\cdots \to \mathcal{C}_{\leq 2} \to \mathcal{C}_{\leq 1} \to \mathcal{C}_{\leq 0}$$

under (colimit-preserving) truncation functors, it will suffice to show that for each $n \geq 0$, the sequence

$$\tau_{\leq n} D(0) \to \tau_{\leq n} D(1) \to \cdots \to \tau_{\leq n} D(k) \to \cdots$$

has a colimit in $\mathcal{C}_{\leq n}$. This is clear, since assertion (4) implies that this sequence is eventually constant. This proves the existence of $X \simeq \lim_{\rightarrow} D(n)$. Moreover, for every integer $n$, we have $\pi_n X \simeq \pi_n (\tau_{\leq n} X) \simeq \pi_n (\tau_{\leq n} D(k)) \simeq \pi_n D(k)$ for $k \gg 0$, which provides the desired isomorphisms $\pi_n X \simeq A_n$. 

\qed
Variant 1.2.4.9. Let $\mathcal{C}$ be a stable $\infty$-category equipped with a $t$-structure, and let $X_\bullet : N(\Delta)^{op} \to \mathcal{C}$ be a semisimplicial object of $\mathcal{C}$. Let $Y_\bullet : N(\Delta)^{op} \to \mathcal{C}$ be the simplicial object of $\mathcal{C}$ obtained by the process of left Kan extension, and let $\{E_1^{p,q}, d_e\}_{r \geq 1}$ be the spectral sequence associated to $Y_\bullet$ by the construction of Remark 1.2.4.4. Unwinding the definitions, we see that for every integer $q$, $\{E_1^{p,q}\}$ is the unnormalized chain complex associated to the semisimplicial object $\pi_q X_\bullet$ of the heart of $\mathcal{C}$. More precisely, we have canonical isomorphisms $E_1^{p,q} \simeq \pi_q X_p$, and the differential $d_1 : E_1^{p,q} \to E_1^{p+1,q}$ is the alternating sum of the face maps $\pi_q X_p \to \pi_q X_{p-1}$ induced by the inclusions $[p-1] \hookrightarrow [p]$.

Example 1.2.4.10. Let $\mathcal{C}$ be a stable $\infty$-category with a left complete $t$-structure, and let $X_\bullet$ be a semisimplicial object of the heart of $\mathcal{C}$. Proposition 1.2.4.5 implies that $X_\bullet$ admits a colimit $X \in \mathcal{C}_{\geq 0}$, whose homotopy groups $\pi_q X$ are given by the homologies of the unnormalized chain complex

$$\cdots \to \pi_0 X_2 \to \pi_0 X_1 \to \pi_0 X_0.$$

Corollary 1.2.4.11. Let $\mathcal{C}$ be a stable $\infty$-category equipped with a left complete $t$-structure, whose heart is equivalent to (the nerve of) an abelian category $A$. Let $X_\bullet$ be a semisimplicial object of $\mathcal{C}_{\geq 0}$, and assume that for every integer $q$ the unnormalized chain complex

$$\cdots \to \pi_q X_2 \to \pi_q X_1 \xrightarrow{\theta_q} \pi_q X_0$$

is an acyclic resolution of the object $A_q = \operatorname{coker}(\theta_q) \in A$. Then:

1. There exists a geometric realization $X = |X_\bullet|$ in $\mathcal{C}$.

2. The object $X$ belongs to $\mathcal{C}_{\geq 0}$, and for $q \geq 0$ the canonical map $\pi_q X_0 \to \pi_q X$ induces an isomorphism $A_q \simeq \pi_q X$.

Proof. Combine Proposition 1.2.4.5 with Variant 1.2.4.9.

Corollary 1.2.4.12. Let $\mathcal{C}$ be a stable $\infty$-category equipped with a $t$-structure which is both right and left complete whose heart is equivalent to (the nerve of) an abelian category $A$. Let $X_\bullet$ be a semisimplicial object of $\mathcal{C}$, and assume that for every integer $q \geq 0$ the unnormalized chain complex

$$\cdots \to \pi_q X_2 \to \pi_q X_1 \xrightarrow{\theta_q} \pi_q X_0$$

is an acyclic resolution of the object $A_q = \operatorname{coker}(\theta_q) \in A$. Then:

1. There exists a geometric realization $X = |X_\bullet|$ in $\mathcal{C}$.

2. For every integer $q$, the canonical map $\pi_q X_0 \to \pi_q X$ induces an isomorphism $A_q \simeq \pi_q X$.

Proof. Since $\mathcal{C}$ is right complete, we can write $X_\bullet$ as the colimit of a sequence of semisimplicial objects $\tau_{\geq -n} X_\bullet$. Using Corollary 1.2.4.11, we deduce that each of the semisimplicial objects $\tau_{\geq -n} X_\bullet$ admits a geometric realization $X(-n) \in \mathcal{C}_{\geq -n}$, whose homotopy group objects are given by

$$\pi_q X(-n) \simeq \begin{cases} A_q & \text{if } q \geq -n \\ 0 & \text{if } q < -n. \end{cases}$$

The right completeness of $\mathcal{C}$ shows that the sequence

$$X(0) \to X(-1) \to X(-2) \to \cdots$$

has a colimit $X \in \mathcal{C}$ such that, for each $n \geq 0$, the map $X(-n) \to X$ induces an equivalence $X(-n) \simeq \tau_{\geq -n} X$; in particular, we canonical isomorphisms $\pi_q X \simeq \pi_q X(-n) \simeq A_q$ for any $n \geq -q$. It follows from Lemma T.5.5.2.3 that we can identify $X$ with a geometric realization $|X_\bullet|$.

\[\square\]
We now turn to the proof of Theorem 1.2.4.1. Recall that if \( C \) is a stable \( \infty \)-category, then a diagram \( \Delta^1 \times \Delta^1 \to C \) is a pushout square if and only if it is a pullback square (Proposition 1.1.3.4). The main step in the proof of Theorem 1.2.4.1 is the following generalization of Proposition 1.1.3.4 to cubical diagrams of higher dimension:

**Proposition 1.2.4.13.** Let \( C \) be a stable \( \infty \)-category, and let \( \sigma : (\Delta^1)^n \to C \) be a diagram. Then \( \sigma \) is a colimit diagram if and only if \( \sigma \) is a limit diagram.

The proof will require a few preliminaries.

**Lemma 1.2.4.14.** Let \( C \) be a stable \( \infty \)-category. A square

\[
\begin{array}{ccc}
X' & \longrightarrow & X \\
\downarrow^{f'} & & \downarrow^f \\
Y' & \longrightarrow & Y
\end{array}
\]

in \( C \) is a pullback if and only if the induced map \( \alpha : \text{cofib}(f') \to \text{cofib}(f) \) is an equivalence.

**Proof.** Form an expanded diagram

\[
\begin{array}{ccc}
X' & \longrightarrow & X & \longrightarrow & 0 \\
\downarrow^{f'} & & \downarrow^f & & \downarrow \\
Y' & \longrightarrow & Y & \longrightarrow & \text{cofib}(f)
\end{array}
\]

where the right square is a pushout. Since \( C \) is stable, the right square is also a pullback. Lemma T.4.4.2.1 implies that the left square is a pullback if and only if the outer square is a pullback, which is in turn equivalent to the assertion that \( \alpha \) is an equivalence. \( \square \)

**Lemma 1.2.4.15.** Let \( C \) be a stable \( \infty \)-category, let \( K \) be a simplicial set, and suppose that \( C \) admits \( K \)-indexed colimits. Let \( \overline{\pi} : K^\circ \times \Delta^1 \to C \) be a natural transformation between a pair of diagrams \( \overline{p}, \overline{q} : K^\circ \to C \). Then \( \overline{\pi} \) is a colimit diagram if and only if \( \text{cofib}(\overline{\pi}) : K^\circ \to C \) is a colimit diagram.

**Proof.** Let \( p = \overline{p} \mid K \), \( q = \overline{q} \mid K \), and \( \alpha = \overline{\pi} \mid K \times \Delta^1 \). Since \( C \) admits \( K \)-indexed colimits, there exist colimit diagrams \( \overline{p}', \overline{q}' : K^\circ \to C \) extending \( p \) and \( q \), respectively. We obtain a square

\[
\begin{array}{ccc}
\overline{p}' & \longrightarrow & \overline{p} \\
\downarrow & & \downarrow \\
\overline{q}' & \longrightarrow & \overline{q}
\end{array}
\]

in the \( \infty \)-category \( \text{Fun}(K^\circ, C) \). Let \( \infty \) denote the cone point of \( K^\circ \). Using Corollary T.4.2.3.10, we deduce that \( \overline{\pi} \) is a colimit diagram if and only if the induced square

\[
\begin{array}{ccc}
\overline{p}'(\infty) & \longrightarrow & \overline{p}(\infty) \\
\downarrow^{f'} & & \downarrow^f \\
\overline{q}'(\infty) & \longrightarrow & \overline{q}(\infty)
\end{array}
\]

is a pushout. According to Lemma 1.2.4.14, this is equivalent to the assertion that the induced map \( \beta : \text{cofib}(f') \to \text{cofib}(f) \) is an equivalence. We conclude by observing that \( \beta \) can be identified with the natural map

\[
\text{lim}(\text{cofib}(\alpha)) \to \text{cofib}(\overline{\pi})(\infty),
\]

which is an equivalence if and only if \( \text{cofib}(\overline{\pi}) \) is a colimit diagram. \( \square \)
Proof of Proposition 1.2.4.13. By symmetry, it will suffice to show that if \( \sigma \) is a colimit diagram, then \( \sigma \) is also a limit diagram. We work by induction on \( n \). If \( n = 0 \), then we must show that every initial object of \( \mathcal{C} \) is also final, which follows from the assumption that \( \mathcal{C} \) has a zero object. If \( n > 0 \), then we may identify \( \sigma \) with a natural transformation \( \alpha : \sigma' \to \sigma'' \) in the \( \infty \)-category \( \text{Fun}((\Delta^1)^{n-1}, \mathcal{C}) \). Assume that \( \sigma \) is a colimit diagram. Using Lemma 1.2.4.15, we deduce that \( \text{cofib}(\alpha) \) is a colimit diagram. Since \( \text{cofib}(\alpha) \simeq \text{fib}(\alpha)[1] \), we conclude that \( \text{fib}(\alpha) \) is a limit diagram. Applying the inductive hypothesis, we deduce that \( \text{fib}(\alpha) \) is a limit diagram. The dual of Lemma 1.2.4.15 now implies that \( \sigma \) is a limit diagram, as desired.

We now turn to the proof of Theorem 1.2.4.1 itself.

Lemma 1.2.4.16. Fix \( n \geq 0 \), and let \( S \) be a subset of the open interval \((0, 1)\) of cardinality \( \leq n \). Let \( Y \) be the set of all sequences of real numbers \( 0 \leq y_1 \leq \ldots \leq y_n \leq 1 \) such that \( S \subseteq \{y_1, \ldots, y_n\} \). Then \( Y \) is a contractible topological space.

Proof. Let \( S \) have cardinality \( m \leq n \), and let \( Z \) denote the set of sequences of real numbers \( 0 \leq z_1 \leq \ldots \leq z_{n-m} \leq 1 \). Then \( Z \) is homeomorphic to a topological \((n-m)\)-simplex. Moreover, there is a homeomorphism \( f : Z \to Y \), which carries a sequence \( \{z_i\} \) to a suitable reordering of the sequence \( \{z_i\} \cup S \).

Lemma 1.2.4.17. Let \( n \geq 0 \), let \( \Delta_{\leq n} \) denote the full subcategory of \( \Delta \) spanned by the objects \( \{[m]\}_{0 \leq m \leq n} \), and let \( \mathcal{J} \) denote the full subcategory of \( (\Delta_{\leq n})/\{n\} \) spanned by the injective maps \([m] \to [n]\). Then the induced map
\[
\text{N}(\mathcal{J}) \to \text{N}(\Delta_{\leq n})
\]
is right cofinal.

Proof. Fix \( m \leq n \), and let \( \mathcal{J} \) denote the category of diagrams
\[
[m] \leftarrow [k] \xrightarrow{i} [n]
\]
where \( i \) is injective. According to Theorem T.4.1.3.1, it will suffice to show that the simplicial set \( \text{N}(\mathcal{J}) \) is weakly contractible (for every \( m \leq n \)).

Let \( X \) denote the simplicial subset of \( \Delta^m \times \Delta^n \) spanned by those nondegenerate simplices whose projection to \( \Delta^n \) is also nondegenerate. Then \( \text{N}(\mathcal{J}) \) can be identified with the barycentric subdivision of \( X \). Consequently, it will suffice to show that the topological space \( |X| \) is contractible. For this, we will show that the fibers of the map \( \phi : |X| \to |\Delta^m| \) are contractible.

We will identify the topological \( m \)-simplex \( |\Delta^m| \) with the set of all sequences of real numbers \( 0 \leq x_1 \leq \ldots \leq x_m \leq 1 \). Similarly, we may identify points of \( |\Delta^n| \) with sequences \( 0 \leq y_1 \leq \ldots \leq y_n \leq 1 \). A pair of such sequences determines a point of \( X \) if and only if each \( x_i \) belongs to the set \( \{0, y_1, \ldots, y_n, 1\} \). Consequently, the fiber of \( \phi \) over the point \( (0 \leq x_1 \leq \ldots \leq x_m \leq 1) \) can be identified with the set
\[
Y = \{0 \leq y_1 \leq \ldots \leq y_n \leq 1 : \{x_1, \ldots, x_m\} \subseteq \{0, y_1, \ldots, y_n, 1\} \} \subseteq |\Delta^n|,
\]
which is contractible (Lemma 1.2.4.16).

Corollary 1.2.4.18. Let \( \mathcal{C} \) be a stable \( \infty \)-category, and let \( F : \text{N}(\Delta_{\leq n})^{\text{op}} \to \mathcal{C} \) be a functor such that \( F([m]) \simeq 0 \) for all \( m < n \). Then there is a canonical isomorphism \( \lim_{\to Y}(F) \simeq X[n] \) in the homotopy category \( h\mathcal{C} \), where \( X = F([n]) \).

Proof. Let \( \mathcal{J} \) be as in Lemma 1.2.4.17, let \( G'' \) denote the composition \( \text{N}(\mathcal{J})^{\text{op}} \to \text{N}(\Delta_{\leq n})^{\text{op}} \to \mathcal{C} \), and let \( G \) denote the constant map \( \text{N}(\mathcal{J})^{\text{op}} \to \mathcal{C} \) taking the value \( X \). Let \( \mathcal{J}_0 \) denote the full subcategory of \( \mathcal{J} \) obtained by deleting the final object. There is a canonical map \( \alpha : G \to G'' \), and \( G' = \text{fib}(\alpha) \) is a left Kan extension of \( G' \mid \text{N}(\mathcal{J}_0)^{\text{op}} \). We obtain a fiber sequence
\[
\lim_{\to Y}(G') \to \lim_{\to Y}(G) \to \lim_{\to Y}(G'')
\]
in the homotopy category hC. Lemma 1.2.4.17 yields an equivalence \( \lim_\to(F) \simeq \lim_\to(G''_n) \), and Lemma T.4.3.2.7 implies the existence of an equivalence \( \lim_\to(G'_n) \simeq \lim_\to(G'_n)[N(\Delta)_{\text{op}}] \).

We now observe that the simplicial set \( N(\partial)_{\text{op}} \) can be identified with the barycentric subdivision of the standard \( n \)-simplex \( \Delta^n \), and that \( N(\partial)_{\text{op}} \) can be identified with the barycentric subdivision of its boundary \( \partial \Delta^n \). It follows (see §T.4.4.4) that we may identify the map \( \lim_\to(G'_n) \to \lim_\to(G) \) with the map \( \beta : X \otimes (\partial \Delta^n) \to X \otimes \Delta^n \). The cofiber of \( \beta \) is canonically isomorphic (in hC) to the \( n \)-fold suspension \( X[n] \) of \( X \).

\[ \square \]

**Lemma 1.2.4.19.** Let \( C \) be a stable \( \infty \)-category, let \( n \geq 0 \), and let \( F : N(\Delta^\leq_{\leq n})_{\text{op}} \to C \) be a functor (here \( \Delta^\leq_{\leq n} \) denotes the full subcategory of \( \Delta^\leq \) spanned by the objects \( \{[k] \}_{1 \leq k \leq n} \)). The following conditions are equivalent:

(i) The functor \( F \) is a right Kan extension of \( F \mid N(\Delta^\leq_{\leq n})_{\text{op}} \).

(ii) The functor \( F \) is a right Kan extension of \( F \mid N(\Delta^\leq_{\leq n-1})_{\text{op}} \).

**Proof.** Condition (ii) is equivalent to the assertion that the composition

\[ F' : N(\Delta^\leq_{\leq n-1})_{\text{op}} \to N(\Delta^\leq_{\leq n})_{\text{op}} \to C \]

is a limit diagram. Let \( J \) denote the full subcategory of \( N(\Delta^\leq_{\leq n-1})_{\text{op}} \) spanned by those maps \( [i] \to [n] \) which are injective. The inclusion \( J \hookrightarrow N(\Delta^\leq_{\leq n})_{\text{op}} \) admits a right adjoint, and is therefore right cofinal. Consequently, condition (ii) is equivalent to the requirement that the restriction \( F' \mid J^s \) is a limit diagram. Since \( J^s \) is isomorphic to \( (\Delta^1)^{n+1} \), Proposition 1.2.4.13 asserts that \( F' \mid J^s \) is a limit diagram if and only if \( F' \mid J^s \) is a colimit diagram. In view of Lemma 1.2.4.17, \( F' \mid J^s \) is a colimit diagram if and only if \( F \) is a colimit diagram, which is equivalent to (i).

\[ \square \]

**Proof of Theorem 1.2.4.1.** Our first step is to describe the desired equivalence in more precise terms. Let \( J_+ \) denote the full subcategory of \( N(\mathbb{Z}_{\geq 0}) \times N(\Delta^\leq)_{\text{op}} \) spanned by those pairs \( (n, [m]) \), where \( m \leq n \), and let \( J \) be the full subcategory of \( J_+ \) spanned by those pairs \( (n, [m]) \) where \( 0 \leq m \leq n \). We observe that there is a natural projection \( p : J \to N(\Delta^\leq)_{\text{op}} \), and a natural embedding \( i : N(\mathbb{Z}_{\geq 0}) \to J_+ \), which carries \( n \geq 0 \) to the object \( (n, [1]) \).

Let \( \text{Fun}(J, C) \) denote the full subcategory of \( \text{Fun}(J_+, C) \) spanned by those functors \( F : J \to C \) such that, for every \( s \leq m \leq n \), the image under \( F \) of the natural map \( (m, [s]) \to (n, [s]) \) is an equivalence in \( C \). Let \( \text{Fun}(J_+, C) \) denote the full subcategory of \( \text{Fun}(J_+, C) \) spanned by functors \( F_+ : J_+ \to C \) such that \( F = F_+ \mid J \). Then the functor \( p \) restricts to an equivalence \( p^\#: J^s \to N(\Delta^\leq_{\leq k})_{\text{op}} \). Let \( \text{Fun}(J^s, C) \) denote the full subcategory of \( \text{Fun}(J^s, C) \) spanned by those functors \( F : J^s \to C \) such that, for every \( s \leq m \leq n \leq k \), the image under \( F \) of the natural map \( (m, [s]) \to (n, [s]) \) is an equivalence in \( C \). We observe that this is equivalent to the condition that \( F \) be a right Kan extension of \( F \mid J^s \). Using Proposition T.4.3.2.15, we deduce that the restriction map \( r : \text{Fun}(J^s, C) \to \text{Fun}(J^s, C) \) is an equivalence of \( \infty \)-categories. Composition with \( p \) induces a functor \( G_k : \text{Fun}(N(\Delta^\leq_{\leq k})_{\text{op}}, C) \to \text{Fun}(N(\Delta^\leq_{\leq k})_{\text{op}}, C) \) which is a section of \( r \). It follows that \( G_k \) is an equivalence of \( \infty \)-categories. We can identify \( G \) with the homotopy inverse limit of the functors \( \text{lim}(G_k) \), so that \( G \) is also an equivalence of \( \infty \)-categories.

The fact that \( G' \) is an equivalence of \( \infty \)-categories follows immediately from Proposition T.4.3.2.15, since for each \( n \geq 0 \) the simplicial set \( J/(n, [1]) \) is finite and \( \mathbb{C} \) admits finite colimits.
We now show that $G'$ is an equivalence of $\infty$-categories. Let $\mathcal{I}^{\leq k}$ denote the full subcategory of $\mathcal{I}_+$ spanned by pairs $(n, [m])$ where either $m \leq n \leq k$ or $m = -1$. We let $D(k)$ denote the full subcategory of $\text{Fun}(\mathcal{I}^{\leq k}_+, \mathcal{C})$ spanned by those functors $F : \mathcal{I}^{\leq k}_+ \to \mathcal{C}$ with the following pair of properties:

(i) For every $0 \leq s \leq m \leq n \leq k$, the image under $F$ of the natural map $(m, [s]) \to (n, [s])$ is an equivalence in $\mathcal{C}$.

(ii) For every $n \leq k$, $F$ is a left Kan extension of $F|\mathcal{I}^{\leq k}_+$ at $(n, [-1])$.

Then $\text{Fun}^0(\mathcal{I}_+, \mathcal{C})$ is the inverse limit of the tower of restriction maps

$$\ldots \to D(1) \to D(0) \to D(-1) = \text{Fun}(N(\mathbb{Z}_{\geq 0}), \mathcal{C}).$$

To complete the proof, we will show that for each $k \geq 0$, the restriction map $D(k) \to D(k - 1)$ is a trivial Kan fibration.

Let $\mathcal{I}^{\leq k}_0$ be the full subcategory of $\mathcal{I}^{\leq k}_+$ obtained by removing the object $(k, [k])$, and let $D'(k)$ be the full subcategory of $\text{Fun}(\mathcal{I}^{\leq k}_0, \mathcal{C})$ spanned by those functors $F$ which satisfy condition (i) and satisfy (ii) for $n < k$. We have restriction maps

$$D(k) \xrightarrow{\theta} D'(k) \xrightarrow{\theta'} D(k - 1).$$

We observe that a functor $F : \mathcal{I}^{\leq k}_0 \to \mathcal{C}$ belongs to $D'(k)$ if and only if $F|\mathcal{I}^{\leq k-1}_0$ belongs to $D(k - 1)$ and $F$ is a left Kan extension of $F|\mathcal{I}^{\leq k-1}_+$ at $(n, [-1])$. Using Proposition T.4.3.2.15, we conclude that $\theta'$ is a trivial Kan fibration.

We will prove that $\theta$ is a trivial Kan fibration by a similar argument. According to Proposition T.4.3.2.15, it will suffice to show that a functor $F : \mathcal{I}^{\leq k}_0 \to \mathcal{C}$ belongs to $D(k)$ if and only if $F|\mathcal{I}^{\leq k}_0$ belongs to $D'(k)$ and $F$ is a right Kan extension of $F|\mathcal{I}^{\leq k}_0$. This follows immediately from Lemma 1.2.4.19 and the observation that the inclusion $\mathcal{I}^{\leq k} \subseteq \mathcal{I}^{\leq k}_0$ is left cofinal.

\[\square\]

### 1.3 Homological Algebra and Derived Categories

Homological algebra provides a rich supply of examples of stable $\infty$-categories. Suppose that $\mathcal{A}$ is an abelian category with enough projective objects. In §1.3.2, we will explain how to associate to $\mathcal{A}$ an $\infty$-category $\mathcal{D}^-(\mathcal{A})$, which we call the \textit{derived $\infty$-category} of $\mathcal{A}$, whose objects can be identified with (right-bounded) chain complexes with values in $\mathcal{A}$. The $\infty$-category $\mathcal{D}^-(\mathcal{A})$ is stable, and its homotopy category $\text{h}\mathcal{D}^-(\mathcal{A})$ can be identified (as a triangulated category) with the usual derived category of $\mathcal{A}$ (as defined, for example, in [160]). Our construction of $\mathcal{D}^-(\mathcal{A})$ uses a variant of the homotopy coherent nerve which is defined for differential graded categories, which we describe in §1.3.1.

As we mentioned in §1.2, the stable $\infty$-category $\mathcal{D}^-(\mathcal{A})$ is equipped with a $t$-structure, and there is a canonical equivalence of abelian categories $\mathcal{A} \to \mathcal{D}^-(\mathcal{A})^\triangledown$. In §1.3.3, we will show that $\mathcal{D}^-(\mathcal{A})$ is universal with respect to these properties. More precisely, if $\mathcal{C}$ is any stable $\infty$-category equipped with a left-complete $t$-structure, then any right exact functor $\mathcal{A} \to \mathcal{C}^\triangledown$ extends (in an essentially unique way) to an exact functor $\mathcal{D}^-(\mathcal{A}) \to \mathcal{C}$ (Proposition 1.3.3.12). This observation can be regarded as providing an abstract approach to the theory of derived functors (see Example 1.3.3.4).

By an entirely parallel discussion, if $\mathcal{A}$ is abelian category with enough \textit{injective} objects, we can associate to $\mathcal{A}$ a left-bounded derived $\infty$-category $\mathcal{D}^+(\mathcal{A})$. This case is in some sense more fundamental: a theorem of Grothendieck asserts that if $\mathcal{A}$ is a presentable abelian category in which filtered colimits are exact, then $\mathcal{A}$ has enough injective objects (Corollary 1.3.5.7). In §1.3.5, we will explain how to associate to such an abelian category an \textit{unbounded} derived $\infty$-category $\mathcal{D}(\mathcal{A})$, which contains $\mathcal{D}^+(\mathcal{A})$ as a full subcategory (as well as $\mathcal{D}^-(\mathcal{A})$, in case $\mathcal{A}$ has enough projective objects). The $\infty$-category $\mathcal{D}(\mathcal{A})$ can be realized as the underlying $\infty$-category of a combinatorial model category $\mathbf{A}$ (whose underlying category is the category of unbounded chain complexes in $\mathcal{A}$). Here some words of caution are in order: $\mathbf{A}$ is not a simplicial model
1.3. HOMOLOGICAL ALGEBRA AND DERIVED CATEGORIES

category in an obvious way, so that the results of [97] do not apply to $\mathcal{A}$ directly. We therefore devote §1.3.4 to a general discussion of $\infty$-categories obtained from arbitrary model categories (or, more generally, categories equipped with a distinguished class of weak equivalences or quasi-isomorphisms) which are not assumed to be simplicial.

In §1.3.6, we specialize to the case where $\mathcal{A}$ is a locally Noetherian abelian category. In this case, there is an enlargement of the $\infty$-category $\mathcal{D}(\mathcal{A})$ which is useful in many applications, whose objects are arbitrary chain complexes $Q_*$ of injective objects of $\mathcal{A}$. Following Krause, we will show that this $\infty$-category is compactly generated, and that its compact objects can be identified with bounded chain complexes whose homologies are Noetherian objects of $\mathcal{A}$ (Theorem 1.3.6.7).

Remark 1.3.0.1. The derived category of an abelian category was introduced in Verdier’s thesis ([155]). A good introductory reference is [160].

1.3.1 Nerves of Differential Graded Categories

Let $\mathcal{A}$ be an additive category. Then the collection of chain complexes with values in $\mathcal{A}$ can be organized into an $\infty$-category $\mathcal{C}$, which may described informally as follows:

- The objects of $\mathcal{C}$ are chain complexes

  $$\cdots \to M_1 \to M_0 \to M_{-1} \to \cdots$$

  with values in $\mathcal{C}$.

- Given objects $M_*, N_* \in \mathcal{C}$, morphisms from $M_*$ to $N_*$ are given by chain complex homomorphisms $f : M_* \to N_*$.

- Given a pair of morphisms $f, g : M_* \to N_*$ in $\mathcal{C}$, 2-morphisms from $f$ to $g$ are given by chain homotopies: that is, collections of maps $h_n : M_n \to N_{n+1}$ satisfying $d \circ h_n + h_{n-1} \circ d = f - g$.

- ...

To make this description precise, we could proceed in several steps:

1. Let $\text{Ch}(\mathcal{A})$ denote the ordinary category introduced in Definition 1.2.3.1: the objects of $\text{Ch}(\mathcal{A})$ are chain complexes with values in $\mathcal{A}$, and the morphisms in $\text{Ch}(\mathcal{A})$ are morphisms of chain complexes.

2. To every pair of objects $M_*, N_* \in \text{Ch}(\mathcal{A})$, we can associate a chain complex of abelian groups $\text{Map}_{\text{Ch}(\mathcal{A})}(M_*, N_*)$, whose homology groups $H_n(\text{Map}_{\text{Ch}(\mathcal{A})}(M_*, N_*))$ are isomorphic to the group of chain homotopy classes of maps from $M_*$ into the shifted chain complex $N_*[m]$ (see Definition 1.3.2.1). By means of this observation, we can regard $\text{Ch}(\mathcal{A})$ as enriched over the category $\text{Ch}(\mathcal{A})$ of chain complexes of abelian groups.

3. The truncation functor $\tau_{\geq 0}$ is a right-lax monoidal functor from the category $\text{Ch}(\mathcal{A})$ to the category $\text{Ch}(\mathcal{A})_{\geq 0}$ of nonnegative graded chain complexes of abelian groups. Applying $\tau_{\geq 0}$ objectwise to the morphism objects in $\text{Ch}(\mathcal{A})$, we can regard $\text{Ch}(\mathcal{A})$ as enriched over the category $\text{Ch}(\mathcal{A})_{\geq 0}$ of nonnegatively graded chain complexes.

4. The Dold-Kan correspondence supplies an equivalence of $\text{Ch}(\mathcal{A})_{\geq 0}$ with the category of simplicial abelian groups (Theorem 1.2.3.7). By means of the Alexander-Whitney construction, we can regard DK as a right-lax monoidal functor. We may therefore regard the category $\text{Ch}(\mathcal{A})$ as enriched over the category of $\text{Fun}(\Delta^{op}, \mathcal{A})$ of simplicial abelian groups.

5. Using the forgetful functor from simplicial abelian groups to simplicial sets, we can regard $\text{Ch}(\mathcal{A})$ as a simplicial category. Since every simplicial abelian group is automatically a Kan complex (Corollary 1.3.2.12), $\text{Ch}(\mathcal{A})$ is automatically fibrant when viewed as a simplicial category.
(6) Applying the homotopy coherent nerve construction (Definition T.1.1.5.5) to the simplicial category Ch(\mathcal{A}), we obtain an \(\infty\)-category \(N(\text{Ch}(\mathcal{A}))\).

However, this turns out to be unnecessarily complicated. In this section, we will explain how to eliminate steps (3), (4), and (5). That is, we describe how to proceed directly from a category over the ring of integers \(\mathbb{Z}\) to an \(\infty\)-category \(N_{dg}(\mathcal{E})\), which we call the \emph{differential graded nerve} of \(\mathcal{E}\). Our main result is that the result of this procedure is canonically equivalent (though not isomorphic) to the homotopy coherent nerve of simplicial category obtained by applying steps (3), (4), and (5) (Proposition 1.3.1.17).

We begin with some general definitions.

**Definition 1.3.1.1.** Let \(k\) be a commutative ring. A \emph{differential graded category} \(\mathcal{C}\) over \(k\) consists of the following data:

- A collection \(\{X,Y,\ldots\}\), whose elements are called the \emph{objects} of \(\mathcal{C}\).
- For every pair of objects \(X\) and \(Y\), a chain complex of \(k\)-modules
  \[
  \cdots \to \text{Map}_\mathcal{C}(X,Y)_1 \to \text{Map}_\mathcal{C}(X,Y)_0 \to \text{Map}_\mathcal{C}(X,Y)_{-1} \to \cdots,
  \]
  which we will denote by \(\text{Map}_\mathcal{C}(X,Y)_*\).
- For every triple of objects \(X, Y, \) and \(Z\), a composition map
  \[
  \text{Map}_\mathcal{C}(Y,Z)_* \otimes_k \text{Map}_\mathcal{C}(X,Y)_* \to \text{Map}_\mathcal{C}(X,Z)_*,
  \]
  which we can identify with a collection of \(k\)-bilinear maps
  \[
  \circ : \text{Map}_\mathcal{C}(Y,Z)_p \times \text{Map}_\mathcal{C}(X,Y)_q \to \text{Map}_\mathcal{C}(X,Z)_{p+q}
  \]
  satisfying the Leibniz rule \(d(g \circ f) = dg \circ f + (-1)^p g \circ df\).
- For each object \(X \in \mathcal{C}\), an \emph{identity morphism} \(\text{id}_X \in \text{Map}_\mathcal{C}(X,X)_0\) such that
  \[
  g \circ \text{id}_X = g \quad \text{id}_X \circ f = f
  \]
  for all \(f \in \text{Map}_\mathcal{C}(Y,X)_p, g \in \text{Map}_\mathcal{C}(X,Y)_q\).

The composition law is required to be associative in the following sense: for every triple \(f \in \text{Map}_\mathcal{C}(W,X)_p, g \in \text{Map}_\mathcal{C}(X,Y)_q, \) and \(h \in \text{Map}_\mathcal{C}(Y,Z)_r\), we have
\[
(h \circ g) \circ f = h \circ (g \circ f).
\]

In the special case where \(k = \mathbb{Z}\) is the ring of integers, we will refer to a differential graded category over \(k\) simply as a \emph{differential graded category}.

**Remark 1.3.1.2.** Let \(\mathcal{C}\) be a differential graded category. For every object \(X\) of \(\mathcal{C}\), the identity morphism \(\text{id}_X\) is a cycle: that is, \(d\text{id}_X = 0\). This follows from the Leibniz rule
\[
d\text{id}_X = d(\text{id}_X \circ \text{id}_X) = (d\text{id}_X) \circ \text{id}_X + \text{id}_X \circ (d\text{id}_X) = 2d\text{id}_X.
\]

**Remark 1.3.1.3.** Let \(\phi : k \to k'\) be a homomorphism of commutative rings. Then every differential graded category over \(k'\) can be regarded as a differential graded category over \(k\) by neglect of structure. In particular, every differential graded category over a commutative ring \(k\) can be regarded as a differential graded category over the ring of integers \(\mathbb{Z}\).

**Remark 1.3.1.4.** If \(k\) is a commutative ring, we can identify differential graded categories over \(k\) with categories enriched over the category \(\text{Ch}(k)\) of chain complexes of \(k\)-modules. In particular, every differential graded category \(\mathcal{C}\) can be regarded as an ordinary category, with morphisms given by \(\text{Hom}_\mathcal{C}(X,Y) = \{f \in \text{Map}_\mathcal{C}(X,Y)_0 : df = 0\}\).
Remark 1.3.1.5. Let $\mathcal{C}$ be a differential graded category. There is another category canonically associated to $\mathcal{C}$, called the \textit{homotopy category} of $\mathcal{C}$ and denoted by $h\mathcal{C}$. It may be defined precisely as follows:

- The objects of $h\mathcal{C}$ are the objects of $\mathcal{C}$.
- The morphisms in $h\mathcal{C}$ are given by the formula
  \[ \text{Hom}_{h\mathcal{C}}(X, Y) = \text{H}_0(\text{Map}_{\mathcal{C}}(X, Y)_*) = \text{coker}(d : \text{Map}_{\mathcal{C}}(X, Y)_1 \to \text{Hom}_{\mathcal{C}}(X, Y)) \].

That is, a morphism in $h\mathcal{C}$ is given by an equivalence class $[f]$ of 0-cycles $f \in \text{Map}_{\mathcal{C}}(X, Y)_0$, where two 0-cycles $f, g \in \text{Map}_{\mathcal{C}}(X, Y)_0$ are regarded as equivalent if there exists an element $z \in \text{Map}_{\mathcal{C}}(X, Y)_1$ with $dz = f - g$.

- Composition of morphisms in $h\mathcal{C}$ is characterized by the formula $[f \circ g] = [f] \circ [g]$.

Construction 1.3.1.6. Let $\mathcal{C}$ be a differential graded category. We will associate to $\mathcal{C}$ a simplicial set $N_{\text{dg}}(\mathcal{C})$, which we call the \textit{differential graded nerve} of $\mathcal{C}$. For each $n \geq 0$, we define $N_{\text{dg}}(\mathcal{C})_n \simeq \text{Hom}_{\text{Set}_\Delta}(\Delta^n, N_{\text{dg}}(\mathcal{C}))$ to be the set of all ordered pairs $\{(X_i)_{0 \leq i \leq n}, \{f_I\}\}$, where:

(a) For $0 \leq i \leq n$, $X_i$ denotes an object of the differential graded category $\mathcal{C}$.

(b) For every subset $I = \{i_0 < i_1 < i_2 < \ldots < i_m\} \subseteq [n]$ with $m \geq 0$, $f_I$ is an element of the abelian group $\text{Map}_{\mathcal{C}}(X_{i_0}, X_{i_m})$, satisfying the equation

\[ df_I = \sum_{1 \leq j \leq m} (-1)^j (f_{I - \{i_j\}} - f_{\{i_{j + 1} < \ldots < i_m\}} \circ f_{\{i_0 < \ldots < i_{j - 1}\}}). \tag{1.1} \]

If $\alpha : [m] \to [n]$ is a nondecreasing function, then the induced map $N_{\text{dg}}(\mathcal{C})_n \to N_{\text{dg}}(\mathcal{C})_m$ is given by

\[ ((X_i)_{0 \leq i \leq n}, \{f_I\}) \mapsto ((X_{\alpha(i)})_{0 \leq i \leq m}, \{g_I\}), \]

where $g_J = \begin{cases} f_{\alpha(J)} & \text{if } \alpha|J \text{ is injective} \\ \text{id}_{X_i} & \text{if } J = \{j, j'\} \text{ with } \alpha(j) = \alpha(j') = i \\ 0 & \text{otherwise}. \end{cases}$

Remark 1.3.1.7. The theory of differential graded categories can be regarded as a special case of the more general theory of $A_\infty$-\textit{categories} (see [131] for an exposition). Construction 1.3.1.6 (and many of the results proven below) can be generalized to the case of an $A_\infty$-category $\mathcal{C}$: for this, one needs to replace equation 1.1 by a more elaborate version, involving the higher-order multiplications on $\mathcal{C}$.

Example 1.3.1.8. Let $\mathcal{C}$ be a differential graded category. Then:

- A 0-simplex of $N_{\text{dg}}(\mathcal{C})$ is simply an object of $\mathcal{C}$.
- A 1-simplex of $N_{\text{dg}}(\mathcal{C})$ is a morphism of $\mathcal{C}$: that is, a pair of objects $X, Y \in \mathcal{C}$ together with an element $f \in \text{Map}_{\mathcal{C}}(X, Y)_0$ satisfying $df = 0$.
- A 2-simplex of $N_{\text{dg}}(\mathcal{C})$ consists of a triple of objects $X, Y, Z \in \mathcal{C}$, a triple of morphisms $f \in \text{Map}_{\mathcal{C}}(X, Y)_0$, $g \in \text{Map}_{\mathcal{C}}(Y, Z)_0$, $h \in \text{Map}_{\mathcal{C}}(X, Z)_0$ satisfying $df = dg = dh = 0$, together with an element $z \in \text{Map}_{\mathcal{C}}(X, Z)_1$ with $dz = (g \circ f) - h$.

Remark 1.3.1.9. Let $\mathcal{C}$ be a differential graded category and let $\mathcal{C}_0$ denote its underlying ordinary category (see Remark 1.3.1.4). Then the simplicial set $N(\mathcal{C}_0)$ is isomorphic to the simplicial subset of the differential graded nerve $N_{\text{dg}}(\mathcal{C})$ whose $n$-simplices are given by pairs $\{(X_i)_{0 \leq i \leq n}, \{f_I\}\}$, where $f_I = 0$ whenever the set $I$ has more than two elements. In particular, the map $N(\mathcal{C}_0) \to N_{\text{dg}}(\mathcal{C})$ is bijective on $n$-simplices for $n \leq 1$. 
Proposition 1.3.1.10. Let $\mathcal{C}$ be a differential graded category. Then the simplicial set $N_{dg}(\mathcal{C})$ is an $\infty$-category.

Proof. Suppose we are given $0 \leq j < n$ and a map $\phi_0 : \Lambda^n_j \to N_{dg}(\mathcal{C})$; we wish to show that $\phi_0$ can be extended to an $n$-simplex of $N_{dg}(\mathcal{C})$. Unwinding the definitions, we see that $\phi_0$ can be identified with the data of a pair $\{(X_i)_{0 \leq i \leq n}, \{f_I\}\}$, where $\{X_i\}_{0 \leq i \leq n}$ is a collection of objects of $\mathcal{C}$ and $f_I \in \text{Map}_C(X_i, X_{i_k})_{k-1}$ is defined for every subset $I = \{i_0 < i_1 < \ldots < i_k\} \subseteq [n]$ with $m \geq 0$ and $I \neq \emptyset$. We want to show that $\phi_0$ is a homotopy equivalence on objects and surjective on morphisms. It therefore suffices to show that for every pair $(X, Y)$ of objects, the equation 1.1 of Construction 1.3.1.6. This data extends uniquely to an $n$-simplex $\{(X_i), \{f_I\}\}$ of $N_{dg}(\mathcal{C})$ satisfying $f_{[n]} = 0$, if we set

$$f_{[n]}(j) = \sum_{0 \leq p \leq j} (-1)^{p-j} f_{\{p, p+1, \ldots, n\}} \circ f_{\{0, \ldots, p\}} - \sum_{0 \leq p < k, k \neq j} (-1)^{p-j} f_{[n]-\{p\}}$$

Remark 1.3.1.11. Let $\mathcal{C}$ be a differential graded category. Then the homotopy category $\text{hN}(\mathcal{C})$ of Remark 1.3.1.5 is canonically isomorphic to the homotopy category $\text{hN}_{dg}(\mathcal{C})$ of the $\infty$-category $N_{dg}(\mathcal{C})$. To see this, let $\mathcal{C}_0$ be the underlying category of $\mathcal{C}$. Remark 1.3.1.9 supplies a map $\mathcal{C}_0 \simeq \text{hN}(\mathcal{C}_0) \to \text{hN}_{dg}(\mathcal{C})$ which is surjective, surjective on objects and surjective on morphisms. It suffices to show that for every pair of objects, the induced equivalence relation on homotopy classes of maps agrees with the relation of homology that is, two cycles $f, g \in \text{Map}_C(X, Y)$ are homologous if and only if $f - g = dz$ for some $z \in \text{Map}_C(X, Y)_{1}$.

Remark 1.3.1.12. Let $\mathcal{D}$ be an $\infty$-category. Recall that for $X, Y \in \mathcal{D}$, the mapping space $\text{Hom}^R_C(X, Y)$ is defined as the simplicial set whose $n$-simplices are maps $\Delta^n \to \mathcal{D}$ which carry the simplicial subset $\Delta^n \subseteq \Delta^{n+1}$ to the vertex $X$ and the opposite vertex $\{n+1\} \subseteq \Delta^{n+1}$ to the vertex $Y$. Unwinding the definitions, we see that an $n$-simplex of $\text{Hom}^R_{N_{dg}(\mathcal{C})}(X, Y)$ is determined by specifying, for every subset $I = \{i_m < i_{m-1} < \ldots < i_0 < n+1\} \subseteq [n+1]$ with $m \geq 0$, an element $f_I \in \text{Map}_C(X, Y)_m$, satisfying the equations

$$-df_I = \sum_{0 \leq j \leq n} (-1)^j f_{I-\{i_j\}}.$$

After a change of signs, we can identify $n$-simplices of $\text{Hom}^R_{N_{dg}(\mathcal{C})}(X, Y)$ with chain complex homomorphisms $N_*(\Delta^n) \to \text{Map}_C(X, Y)_*$. This identification is functorial in $\Delta^n$, and (using Lemma 1.2.3.12) yields an isomorphism of simplicial sets

$$\text{Hom}^R_{N_{dg}(\mathcal{C})}(X, Y) \simeq \text{DK}_{\bullet}(\tau_{\geq 0} \text{Map}_C(X, Y)).$$

where $\text{DK}_{\bullet}$ denotes the functor given by the Dold-Kan correspondence (see Construction 1.2.3.5).

Our next goal is to compare the formation of differential graded nerves of differential graded categories (Construction 1.3.1.6) with the formation of homotopy coherent nerves of simplicial categories ($\S$ 1.1.5).

Construction 1.3.1.13. Let $\text{Ab}$ denote the category of abelian groups. Using the Alexander-Whitney construction, we see that the composite functor

$$
\text{Ch}(\text{Ab}) \xrightarrow{\tau_{\geq 0}} \text{Ch}(\text{Ab})_{\geq 0} \xrightarrow{\text{DK}} \text{Fun}(\Delta^{op}, \text{Ab}) \to \text{Fun}(\Delta^{op}, \text{Set}) = \text{Set}_\Delta
$$

is right-lax monoidal (see Example 1.2.3.26). In particular, every differential graded category $\mathcal{C}$ determines a simplicial category $\mathcal{C}_\Delta$, which may be described more concretely as follows:
1.3. HOMOLOGICAL ALGEBRA AND DERIVED CATEGORIES

- The objects of $\mathcal{C}_\Delta$ are the objects of $\mathcal{C}$.

- Given objects $X, Y \in \mathcal{C}$, the mapping space $\text{Map}_{\mathcal{C}_\Delta}(X, Y)$ is the underlying simplicial set of the simplicial abelian group $DK_\ast \left( \tau \geq 0 \text{Map}_\mathcal{C}(X, Y) \right)$.

We will refer to $\mathcal{C}_\Delta$ as the underlying simplicial category of $\mathcal{C}$.

**Remark 1.3.1.14.** For every differential graded category $\mathcal{C}$, the underlying simplicial category $\mathcal{C}_\Delta$ is automatically fibrant (see Remark 1.2.3.14).

**Notation 1.3.1.15.** Let $\mathcal{C}$ be a simplicial category. Recall that the simplicial set $N(\mathcal{C})$ is defined by the formula

$$N(\mathcal{C})_n = \text{Hom}_\text{cat}_{\Delta}(\mathcal{C}[\Delta^n], \mathcal{C}),$$

where $\mathcal{C}[\Delta^n]$ denotes the category with set of objects $\{0, 1, \ldots, n\}$ and

$$\text{Map}_{\mathcal{C}[\Delta^n]}(i, j) = \begin{cases} \emptyset & \text{if } i > j \\ N(P_{i,j}) & \text{if } i \leq j, \end{cases}$$

where $P_{i,j}$ is the partially ordered set consisting of those subsets $S \subseteq [n]$ having least element $i$ and greatest element $j$. Composition in $\mathcal{C}[\Delta^n]$ is induced by the maps $P_{i,j} \times P_{j,k} \to P_{i,k}$ given by $(S, T) \mapsto S \cup T$.

Let $I = \{i_- < i_m < \ldots < i_1 < i_+\}$ be a subset of $[n]$ and let $\sigma \in \Sigma_m$ be a permutation of the set $\{1, \ldots, m\}$. We let $\tau_{I, \sigma}$ denote the $m$-simplex of $\text{Map}_{\mathcal{C}[\Delta^n]}(i_-, i_+)$ given by the chain

$$\{i_-, i_+\} \subset \cdots \subset \{i_-, i_\sigma(1), i_\sigma(2), i_+\} \subset \cdots \subset \{i_-, i_\sigma(1), \ldots, i_\sigma(m), i_+\}$$

in the partially ordered set $P_{i_-, i_+}$.

**Construction 1.3.1.16.** Let $\mathcal{C}$ be a differential graded category. For every $n$-simplex $\tau \in \text{Map}_{\mathcal{C}_\Delta}(X, Y)_n$, we let $[\tau] \in \text{Map}_{\mathcal{C}}(X, Y)_n$ denote the corresponding $n$-chain. Let $\alpha : \mathcal{C}[\Delta^n] \to \mathcal{C}_\Delta$ be a functor of simplicial categories. For every subset $I = \{i_- < i_m < \ldots < i_1 < i_+\} \subseteq [n]$, we set

$$f_I = \sum_{\sigma \in \Sigma_m} (-1)^\sigma [\alpha(\tau_{I, \sigma})] \in \text{Map}_{\mathcal{C}}(\alpha(i_-), \alpha(i_+))_m$$

where $\tau_{I, \sigma}$ is defined as in Notation 1.3.1.15 and $(-1)^\sigma$ denotes the sign of the permutation $\sigma$. A straightforward calculation shows that

$$df_I = \sum_{1 \leq j \leq m} (-1)^j (f_{i_1 < \ldots < i_m < i_+} \circ f_{i_- < i_1 < \ldots < i_j} - f_{i_- < \ldots < i_j})$$

so that we can regard the pair $([\alpha(i)]_{0 \leq i \leq n}, \{f_I\})$ as an $n$-simplex of $N_{dg}(\mathcal{C})$. This construction determines a map of sets $N(\mathcal{C}_\Delta)_n \to N_{dg}(\mathcal{C})_n$ which depends functorially on the linearly ordered set $[n]$, and therefore defines a functor of $\infty$-categories $N(\mathcal{C}_\Delta) \to N_{dg}(\mathcal{C})$. If $\mathcal{C}$ is a differential graded category, then the map $N(\mathcal{C}_\Delta) \to N_{dg}(\mathcal{C})$ of Construction 1.3.1.16 is bijective when restricted to simplices of dimension $\leq 2$. It is generally not an isomorphism. However, we do have the following result:

**Proposition 1.3.1.17.** Let $\mathcal{C}$ be a differential graded category. Then the functor $\theta : N(\mathcal{C}_\Delta) \to N_{dg}(\mathcal{C})$ of Construction 1.3.1.16 is an equivalence of $\infty$-categories.

**Proof.** Since $\theta$ is bijective on vertices, it will suffice to show that $\theta$ is fully faithful. Choose objects $X, Y \in \mathcal{C}$; we claim that $\theta$ induces a homotopy equivalence of Kan complexes $\phi : \text{Hom}_{N(\mathcal{C}_\Delta)}(X, Y) \to \text{Hom}_{N_{dg}(\mathcal{C})}(X, Y)$. 

Let $Q^\bullet$ be the cosimplicial object of $\mathbf{Set}_\Delta$ defined in §T.2.2.2, so that we have a canonical isomorphism of simplicial sets
\[
\text{Hom}^R_{N(\mathbf{Set}_\Delta)}(X,Y) \simeq \text{Sing}_{Q^\bullet} \text{Map}_{\mathbf{Set}_\Delta}(X,Y) \simeq \text{Sing}_{Q^\bullet}\tau_{\geq 0} \text{Map}_C(X,Y)_*.
\]
(see Proposition T.2.2.2.13). Remark 1.3.1.12 yields an isomorphism of simplicial sets $\text{Hom}^R_{\text{Sing}_{Q^\bullet}}(X,Y) \simeq \tau_{\geq 0} \text{Map}_C(X,Y)_*).$ Let $\Delta^\bullet$ denote the cosimplicial object of $\mathbf{Set}_\Delta$ given by $[n] \mapsto \Delta^n$, so that we have a map $Q^\bullet \to \Delta^\bullet$ of cosimplicial objects of $\mathbf{Set}_\Delta$ (see Proposition T.2.2.2.7) which induces a map $\psi_Z : Z \to \text{Sing}_{Q^\bullet} Z$ for every simplicial set $Z$. When $Z = \tau_{\geq 0} \text{Map}_C(X,Y)_*$, the composite map $\phi \circ \psi_Z$ is an isomorphism of simplicial sets. It will therefore suffice to show that $\psi_Z$ is a homotopy equivalence. Since $Z$ is a Kan complex, this follows from Propositions T.2.2.2.9 and T.2.2.2.7.

We now discuss the functoriality of the construction $\mathcal{C} \mapsto \text{N}_{\text{dg}}(\mathcal{C})$.

**Definition 1.3.1.18.** Let $\mathcal{C}$ and $\mathcal{D}$ be differential graded categories over a field $k$. A differential graded functor $F$ from $\mathcal{C}$ to $\mathcal{D}$ consists of the following data:

- For every object $X \in \mathcal{C}$, an object $F(X) \in \mathcal{D}$.
- For every pair of objects $X,Y \in \mathcal{C}$, a map of chain complexes
  \[
  \alpha_{X,Y} : \text{Map}_C(X,Y)_* \to \text{Map}_D(F(X),F(Y))_.
  \]

This data is required to be compatible with composition in the following sense:

- For every $X \in \mathcal{C}$, we have $\alpha_{X,X} \circ \text{id}_X = \text{id}_{F(X)}$.
- For every triple of objects $X,Y,Z \in \mathcal{C}$ and every $f = \text{Map}_C(X,Y)_p$, $g = \text{Map}_C(Y,Z)_q$, we have $\alpha_{X,Z}(g \circ f) = \alpha_{Y,Z}(g) \circ \alpha_{X,Y}(f)$.

The collection of differential graded categories over $k$ forms a category $\text{Cat}_{\text{dg}} k$, whose morphisms are given by differential graded functors.

**Proposition 1.3.1.19.** Let $k$ be a commutative ring. There is a combinatorial model structure on the category $\text{Cat}_{\text{dg}} k$ of differential graded categories over $k$, which is characterized by the following properties:

(W) A differential graded functor $F : \mathcal{C} \to \mathcal{D}$ is a weak equivalence if and only if $F$ induces an equivalence of homotopy categories $\text{hC} \to \text{hD}$ and, for every pair of objects $X,Y \in \mathcal{C}$, the induced map $\text{Map}_C(X,Y)_* \to \text{Map}_D(F(X),F(Y))_*$ is a quasi-isomorphism of chain complexes of $k$-modules.

(F) A differential graded functor $F : \mathcal{C} \to \mathcal{D}$ is a fibration if and only if $F$ satisfies the following pair of conditions:

- The underlying functor $\text{hC} \to \text{hD}$ is a quasi-fibration. That is, given an object $X \in \mathcal{C}$ and an isomorphism $\beta : F(X) \to Y$ in $\text{hD}$, $\beta$ can be lifted to an isomorphism $\overline{\beta} : X \to \overline{Y}$ in $\text{hC}$.
- For every pair of objects $X,Y \in \mathcal{C}$, the map of chain complexes
  \[
  \text{Map}_C(X,Y)_* \to \text{Map}_D(F(X),F(Y))_*
  \]
  is degreewise surjective.

For a proof, we refer the reader to [141] (in the case where $k$ is a field, Proposition 1.3.1.19 can be deduced from Proposition T.A.3.2.4 and Theorem T.A.3.2.24).

**Proposition 1.3.1.20.** Let $k$ be a commutative ring. Then the formation of differential graded nerves $\mathcal{C} \mapsto \text{N}_{\text{dg}}(\mathcal{C})$ determines a right Quillen functor from the category $\text{Cat}_{\text{dg}} k$ (endowed with the model structure of Proposition 1.3.1.19) to the category of simplicial sets (endowed with the Joyal model structure).
Proof. The functor \( N_{\text{dg}} \) preserves small limits and filtered colimits, and therefore admits a left adjoint by virtue of the adjoint functor theorem (Corollary T.5.5.2.9). We next claim that the functor \( N_{\text{dg}} \) preserves weak equivalences. Let \( F : \mathcal{C} \to \mathcal{D} \) be a weak equivalence of differential graded categories over \( k \). Then \( F \) induces an equivalence of homotopy categories \( h\mathcal{C} \to h\mathcal{D} \). Using Remark 1.3.1.11, we deduce that \( N_{\text{dg}}(F) : N_{\text{dg}}(\mathcal{C}) \to N_{\text{dg}}(\mathcal{D}) \) induces an equivalence of homotopy categories. To prove that \( N_{\text{dg}}(F) \) is an equivalence of \( \infty \)-categories, it suffices to show that it is fully faithful. In other words, we must show that for every pair of objects \( X, Y \in \mathcal{C} \), the induced map \( \text{Hom}^R_{N_{\text{dg}}(\mathcal{C})}(X, Y) \to \text{Hom}^R_{N_{\text{dg}}(\mathcal{D})}(F(X), F(Y)) \) is a homotopy equivalence of Kan complexes. This follows immediately from Remark 1.3.1.12, since the map of chain complexes \( \text{Map}_C(X, Y) \to \text{Map}_D(F(X), F(Y)) \) is a quasi-isomorphism.

To complete the proof, it will suffice to show that the functor \( N_{\text{dg}} \) preserves fibrations. Let \( F : \mathcal{C} \to \mathcal{D} \) be a fibration of differential graded categories over \( k \). We wish to prove that \( F \) induces a categorical fibration of simplicial sets \( N_{\text{dg}}(\mathcal{C}) \to N_{\text{dg}}(\mathcal{D}) \). The functor \( F \) induces a quasi-fibration of ordinary categories \( h\mathcal{C} \to h\mathcal{D} \), and therefore also a quasi-fibration \( hN_{\text{dg}}(\mathcal{C}) \to hN_{\text{dg}}(\mathcal{D}) \) (Remark 1.3.1.11). It will therefore suffice to show that the map \( N_{\text{dg}}(F) \) is an inner fibration of simplicial sets (Corollary T.2.4.6.5). That is, we must show that for \( 0 < j < n \), every lifting problem of the form

\[
\begin{array}{c}
\Lambda^n_j \downarrow \phi \\
\Delta^n_j \downarrow \phi
\end{array}
\]

admits a solution. The map \( \phi \) determines objects \( X_0, X_1, \ldots, X_n \in \mathcal{C} \) together with elements \( f_i \in \text{Map}_C(X_{i-1}, X_i) \) for every subset \( I = \{i_0 < i_1 < \ldots < i_m \} \subseteq [n] \) with at least two elements such that \( [n] \neq I \neq [n] - \{j\} \), satisfying equation 1.1 of Construction 1.3.1.6. For every \( I \), let \( J_I \) denote the image of \( f_I \) in \( \text{Map}_D(F(X_{i-1}), F(X_i)) \). The extension \( \phi \) determines a pair of elements

\[
J_{[n]} \in \text{Map}_D(F(X_0), F(X_n)), J_{[n]-\{j\}} \in \text{Map}_D(F(X_0), F(X_n))_{n-2}
\]

\[
dJ_{[n]} = \sum_{1 \leq i \leq n-1} (-1)^{n-i}(J_{[n]-\{i\}} - J_{\{i\ldots n\}} \circ J_{\{0,\ldots i\}}).
\]

Since \( F \) is a fibration, we can lift \( J_{[n]} \) to an element \( f_{[n]} \in \text{Map}_C(X_0, X_n)_{n-1} \). This choice of lift extends uniquely to an \( n \)-simplex of \( N_{\text{dg}}(\mathcal{C}) \) lifting \( \phi \), by setting

\[
f_{[n]-\{j\}} = (-1)^{n-\{j\}} f_{[n]} + \sum_{1 \leq i \leq n-1} (-1)^{i-\{j\}} f_{\{i\ldots n\}} \circ f_{\{0,\ldots i\}} - \sum_{1 \leq i \leq n-1, i \neq j} (-1)^{i-\{j\}} f_{[n]-\{i\}}.
\]

\[\square\]

### 1.3.2 Derived \( \infty \)-Categories

Let \( \mathcal{A} \) be an abelian category. To every pair of objects \( X, Y \in \mathcal{A} \) and every integer \( n \geq 0 \), one can define a (Yoneda) Ext-group \( \text{Ext}^n_{\mathcal{A}}(X, Y) \). If \( \mathcal{A} \) has enough projective objects, then \( X \) admits a projective resolution

\[
\cdots \to P_2 \to P_1 \to P_0 \to X,
\]

and the Ext-groups \( \text{Ext}^n_{\mathcal{A}}(X, Y) \) are given by the cohomologies of the cochain complex \( \text{Hom}_\mathcal{A}(P_\bullet, Y) \). The functors \( \text{Ext}^n_{\mathcal{A}} \) are examples of derived functors; that is, they are functors which can be computed by choosing a projective (or injective) resolution of one of their arguments. In working with derived functors, it is often convenient to replace the abelian category \( \mathcal{A} \) by its derived category; that is, to work not with objects of \( \mathcal{A} \) but with chain complexes of objects of \( \mathcal{A} \). In this section, we will study a slightly more elaborate object: the derived \( \infty \)-category \( \mathcal{D}^- (\mathcal{A}) \) of an abelian category \( \mathcal{A} \). Roughly speaking, \( \mathcal{D}^- (\mathcal{A}) \) is an \( \infty \)-category whose
objects are (projective and right-bounded) chain complexes with values in $\mathcal{A}$, whose morphisms are given by maps of chain complexes, 2-morphisms are given by chain homotopies, and so forth. Our goal in this section is to define the stable $\infty$-category $\mathcal{D}^-(\mathcal{A})$ and establish some of its basic properties. In particular, we will show that $\mathcal{D}^-(\mathcal{A})$ is stable (Corollary 1.3.2.18) and admits a t-structure, whose heart can be identified with the abelian category $\mathcal{A}$ (Proposition 1.3.2.19).

**Definition 1.3.2.1.** Let $\mathcal{A}$ be an additive category, and let $M_*$ and $N_*$ be chain complexes with values in $\mathcal{A}$ (see Definition 1.2.3.1). For each integer $p$, we let $\text{Map}_{\text{Ch}(\mathcal{A})}(M_*, N_*)_p$ denote the product $\prod_{n \in \mathbb{Z}} \text{Hom}_{\mathcal{A}}(M_n, N_{n+p})$. We will regard the collection

$$\{\text{Map}_{\text{Ch}(\mathcal{A})}(M_*, N_*)_p\}_{p \in \mathbb{Z}}$$

as a chain complex of abelian groups, with differential given by the formula

$$(df)(x) = d(f(x)) - (-1)^p f(dx)$$

for $f \in \text{Map}_{\text{Ch}(\mathcal{A})}(M_*, N_*)_p$.

Given a triple of chain complexes $M_*, N_*, P_* \in \text{Ch}(\mathcal{A})$, composition gives a bilinear map

$$\text{Map}_{\text{Ch}(\mathcal{A})}(N_*, P_*)_p \times \text{Map}_{\text{Ch}(\mathcal{A})}(M_*, N_*)_q \rightarrow \text{Map}_{\text{Ch}(\mathcal{A})}(M_*, P_*)_{p+q}$$

satisfying the Leibniz rule $d(f \circ g) = df \circ g + (-1)^p f \circ dg$. Using this notion of composition, we can regard $\text{Ch}(\mathcal{A})$ as a differential graded category.

**Remark 1.3.2.2.** For every additive category $\mathcal{A}$, we can apply Construction 1.3.1.6 to the differential graded category $\text{Ch}(\mathcal{A})$ to obtain an $\infty$-category $\text{N}_{\text{dg}}(\text{Ch}(\mathcal{A}))$. Note that the objects of $\text{N}_{\text{dg}}(\text{Ch}(\mathcal{A}))$ are chain complexes $M_*$ with values in $\mathcal{A}$ and the morphisms in $\text{N}_{\text{dg}}(\text{Ch}(\mathcal{A}))$ are morphisms of chain complexes. Two morphisms $f, g : M_* \rightarrow N_*$ are homotopic in $\text{N}_{\text{dg}}(\text{Ch}(\mathcal{A}))$ if and only if there exists a chain homotopy from $f$ to $g$: that is, if and only if there is a sequence of maps $h_n : M_n \rightarrow N_{n+1}$ satisfying

$$d \circ h_n + h_{n-1} \circ d = f - g.$$

**Remark 1.3.2.3.** Let $\mathcal{A}$ be an additive category, and let $X_*, Y_* \in \text{Ch}(\mathcal{A})$. The homotopy group

$$\pi_n \text{Map}_{\text{Ch}(\mathcal{A})}(X_*, Y_*)$$

can be identified with the group of chain-homotopy classes of maps from $X_*$ to the shifted complex $Y_{*+n}$.

**Definition 1.3.2.4.** Let $\mathcal{A}$ be an abelian category. An object $P \in \mathcal{A}$ is said to be projective if, for every epimorphism $M \rightarrow N$ in $\mathcal{A}$, the induced map $\text{Hom}_{\mathcal{A}}(P, M) \rightarrow \text{Hom}_{\mathcal{A}}(P, N)$ is surjective. We say that $\mathcal{A}$ has enough projective objects if, for every object $M \in \mathcal{A}$, there exists an epimorphism $P \rightarrow M$, where $P$ is a projective object of $\mathcal{A}$.

**Remark 1.3.2.5.** Let $\mathcal{A}$ be an abelian category. Then an object $P \in \mathcal{A}$ is projective in the sense of Definition 1.3.2.4 if and only if it is projective in the sense of Definition T.5.5.8.18, when regarded as an object of the $\infty$-category $\mathcal{N}(\mathcal{A})$ (see Example T.5.5.8.21).

**Notation 1.3.2.6.** Let $\mathcal{A}$ be an additive category. We let $\text{Ch}^-(\mathcal{A})$ denote the full subcategory of $\text{Ch}(\mathcal{A})$ spanned by those chain complexes $M_*$ such that $M_n \simeq 0$ for $n \ll 0$, and $\text{Ch}^+(\mathcal{A})$ the full subcategory of $\text{Ch}(\mathcal{A})$ spanned by those chain complexes such that $M_n \simeq 0$ for $n \gg 0$.

**Definition 1.3.2.7.** Let $\mathcal{A}$ be an abelian category with enough projective objects. We let $\mathcal{D}^-\mathcal{A}$ denote the $\infty$-category $\text{N}_{\text{dg}}(\text{Ch}^-(\mathcal{A}_{\text{proj}}))$. We will refer to $\mathcal{D}^-\mathcal{A}$ as the derived $\infty$-category of $\mathcal{A}$.

**Variant 1.3.2.8.** If $\mathcal{A}$ is an abelian category with enough injective objects, we let $\mathcal{D}^+\mathcal{A}$ denote the nerve $\text{N}_{\text{dg}}(\text{Ch}^+(\mathcal{A}_{\text{inj}}))$, where $\mathcal{A}_{\text{inj}}$ denotes the full subcategory of $\mathcal{A}$ spanned by the injective objects. We have a canonical equivalence $\mathcal{D}^+\mathcal{A}^{\text{op}} \simeq \mathcal{D}^-\mathcal{A}^{\text{op}}$. 
Remark 1.3.2.9. The homotopy category \( \text{hD}^- (A) \) can be described as follows: objects are given by (right bounded) chain complexes of projective objects of \( A \), and morphisms are given by homotopy classes of chain maps. Consequently, \( \text{hD}^- (A) \) can be identified with the derived category of \( A \) studied in classical homological algebra (with appropriate boundedness conditions imposed).

Our first goal in this section is to verify the stability of the derived category of an abelian category. We begin by studying a more general situation.

**Proposition 1.3.2.10.** Let \( A \) be an additive category. Then the \( \infty \)-category \( \text{Nd}_s (\text{Ch}(A)) \) is stable.

The proof of Proposition 1.3.2.10 will require some preliminary calculations. We will need the following simple observation:

**Proposition 1.3.2.11.** Let \( f : A_\bullet \to B_\bullet \) be a map of simplicial abelian groups. Then \( f \) is a Kan fibration if and only if the associated map of chain complexes \( N_* (A) \to N_* (B) \) induces a surjection \( N_n (A) \to N_n (B) \) for \( n > 0 \).

**Proof.** For every integer \( n \), let \( E(n)_* \) denote the acyclic chain complex given by

\[
E(n)_k = \begin{cases} \mathbb{Z} & \text{if } k \in \{n, n-1\} \\ 0 & \text{otherwise}, \end{cases}
\]

where the differential \( E(n)_n \to E(n)_{n-1} \) is an isomorphism. We note that \( E(n)_* \) enjoys the following universal property: if \( M_* \) is any chain complex in the category \( \text{Ab} \) of abelian groups, then there is a canonical isomorphism \( \text{Hom}_{\text{Ch}(\text{Ab})} (E(n)_*, M_n) \cong M_n \). In particular, there is a map \( \theta : E(n)_* \to N_* (\Delta^n) \) corresponding to a generator of the group \( N_n (\Delta^n) \cong \mathbb{Z} \). Assume that \( n > 0 \). For any \( 0 \leq i \leq n \), the map \( \theta \) determines an isomorphism \( N_* (\Delta^n) \oplus E(n)_n \to N_* (\Delta^n) \). Consequently, the map \( N_* (A) \to N_* (B) \) has the right lifting property with respect to the inclusion \( N_* (\Delta^n) \hookrightarrow N_* (\Delta^n) \) if and only if it has the extension property with respect to \( E(n)_n \). Invoking the universal property of \( E(n)_* \), we see that this lifting property is equivalent to the requirement that the map \( N_n (A) \to N_n (B) \) is surjective. \( \square \)

**Corollary 1.3.2.12.** Let \( A_\bullet \) be a simplicial abelian group. Then \( A_\bullet \) is a Kan complex.

**Notation 1.3.2.13.** Let \( A \) be an additive category. We let \( \text{Ch}(A)_\Delta \) underlying simplicial category of the differential graded category \( \text{Ch}(A) \) (see Construction 1.3.1.13).

Suppose we are given a map \( f : M_* \to M'_* \) of chain complexes with values in an additive category \( A \), and let \( Q_* \in \text{Ch}(A) \) be another chain complex. Composition with \( f \) induces a map of chain complexes

\[
\theta : \text{Map}_{\text{Ch}(A)} (M'_*, Q_*) \to \text{Map}_{\text{Ch}(A)} (M_*, Q_*).
\]

Suppose that, for every pair of integers \( p < q \), \( f \) induces a surjection \( \text{Hom}_A (M'_p, Q_q) \to \text{Hom}_A (M_p, Q_q) \). It follows from Proposition 1.3.2.11 that \( f \) induces a Kan fibration of simplicial sets \( \text{Map}_{\text{Ch}(A)_\Delta} (M'_*, Q_*) \to \text{Map}_{\text{Ch}(A)_\Delta} (M_*, Q_*) \). In particular, we have the following result:

**Corollary 1.3.2.14.** Let \( A \) be an additive category. Suppose we are given a map of chain complexes \( f : M_* \to M'_* \) in \( \text{Ch}(A) \) and another chain complex \( Q_* \) in \( \text{Ch}(A) \). Assume that, for every pair of integers \( p < q \), composition with \( f \) induces a surjection \( \text{Hom}_A (M'_p, Q_q) \to \text{Hom}_A (M_p, Q_q) \). Then \( f \) induces a Kan fibration of simplicial sets \( \text{Map}_{\text{Ch}(A)_\Delta} (M'_*, Q_*) \to \text{Map}_{\text{Ch}(A)_\Delta} (M_*, Q_*) \).

**Remark 1.3.2.15.** The hypotheses of Corollary 1.3.2.14 are satisfied in either of the following situations:

(a) The map \( f \) is **degreewise split**: that is, each of the maps \( M_p \to M'_p \) admits a left inverse.

(b) The category \( A \) is abelian, each of the maps \( M_p \to M'_p \) is a monomorphism, and each of the objects \( Q_q \in A \) is injective.
Corollary 1.3.2.16. Let $A$ be an additive category, and suppose we are given a pushout diagram $\sigma$:

$$
\begin{array}{ccc}
M_* & \xrightarrow{f} & M'_* \\
\downarrow & & \downarrow \\
N_* & \xrightarrow{g} & N'_*
\end{array}
$$

in $\text{Ch}(A)$. If $f$ is degreewise split (as in Remark 1.3.2.15), then $\sigma$ is a homotopy pushout diagram in the simplicial category $\text{Ch}(A)_\Delta$.

**Proof.** We must show that for any $Q_* \in \text{Ch}(A)$, the diagram of Kan complexes

$$
\begin{array}{ccc}
\text{Map}_{\text{Ch}(A)_\Delta}(N'_*, Q_*) & \longrightarrow & \text{Map}_{\text{Ch}(A)_\Delta}(N_*, Q_*) \\
\downarrow & & \downarrow \\
\text{Map}_{\text{Ch}(A)_\Delta}(M'_*, Q_*) & \xrightarrow{g} & \text{Map}_{\text{Ch}(A)_\Delta}(M_*, Q_*)
\end{array}
$$

is a homotopy pullback square. This diagram is evidently a pullback square. Since the Kan model structure on $\text{Set}_\Delta$ is right proper, it suffices to observe that the map $g$ is a Kan fibration (by Corollary 1.3.2.14). 

**Remark 1.3.2.17.** Let $A$ be an additive category, and suppose we are given any map $f : M_* \to M'_*$ in $\text{Ch}(A)$. We have a pushout diagram of chain complexes

$$
\begin{array}{ccc}
M_* & \longrightarrow & E(1)_* \otimes M_* \\
\downarrow & & \downarrow \\
M'_* & \longrightarrow & C(f)_*
\end{array}
$$

where $C(f)_*$ is the *mapping cone* of $f$ (so that $C(f)_n \simeq M'_n \oplus M_{n-1}$). It follows from Corollary 1.3.2.16, Theorem T.4.2.4.1, and Proposition 1.3.1.17 that $C(f)_*$ can be identified with a cofiber of $f$ in the $\infty$-category $\text{N}_{\text{dg}}(\text{Ch}(A))$.

**Proof of Proposition 1.3.2.10.** Let $A$ be an additive category. We first claim that the $\infty$-category $\text{N}_{\text{dg}}(\text{Ch}(A))$ admits pushouts. Using Proposition 1.3.1.17 and Theorem T.4.2.4.1, we are reduced to proving that the simplicial category $\text{Ch}(A)_\Delta$ admits homotopy pushouts. This follows from Corollary 1.3.2.16, since any map of chain complexes $f : M_* \to M'_*$ is chain homotopy-equivalent to a map which is degreewise split (replace $M'_*$ by the mapping cylinder of $f$).

It is obvious that $\text{N}_{\text{dg}}(\text{Ch}(A))$ has a zero object (since $\text{Ch}(A)$ has a zero object). We can describe the suspension functor explicitly as follows. Let $E(1)_*$ be the chain complex of abelian groups described in Proposition 1.3.2.11. There is a pushout diagram of differential graded functors from $\text{Ch}(A)$ to itself, which carries each $M_* \in \text{Ch}(A)$ to the diagram

$$
\begin{array}{ccc}
M_* & \longrightarrow & E(1)_* \otimes M_* \\
\downarrow & & \downarrow \\
0 & \longrightarrow & M_{*-1}.
\end{array}
$$

The above arguments show that this diagram determines a pushout diagram in the $\infty$-category of functors from $\text{N}_{\text{dg}}(\text{Ch}(A))$ to itself. Note that $E(1)_* \otimes M_*$ is chain homotopy contractible and therefore a zero object of $\text{N}_{\text{dg}}(\text{Ch}(A))$. It follows that the suspension functor $\Sigma : \text{N}_{\text{dg}}(\text{Ch}(A)) \to \text{N}_{\text{dg}}(\text{Ch}(A))$ is induced by the shift functor $M_* \mapsto M_{*-1}$. Since the shift functor is an equivalence of differential graded categories, $\Sigma$ is an equivalence of $\infty$-categories. Using Proposition 1.4.2.27, we deduce that $\text{N}_{\text{dg}}(\text{Ch}(A))$ is stable, as desired.
In the situation of Proposition 1.3.2.10, suppose that \( \mathcal{C} \) is a full subcategory of \( \text{Ch}(A) \), which is closed under the formation of shifts and under the formation of mapping cones. Then the differential graded nerve \( N_{dg}(\mathcal{C}) \) is a stable subcategory of \( N_{dg}(\text{Ch}(A)) \), and is therefore itself a stable \( \infty \)-category. In particular, we obtain the following result:

**Corollary 1.3.2.18.** Let \( A \) be an abelian category with enough projective objects. Then the \( \infty \)-category \( \mathcal{D}^-(A) \) is stable.

We next construct a t-structure on the stable \( \infty \)-category \( \mathcal{D}^-(A) \).

**Proposition 1.3.2.19.** Let \( A \) be an abelian category with enough projective objects. Let \( \mathcal{D}^-_{\geq 0}(A) \) denote the full subcategory of \( \mathcal{D}^-(A) \) spanned by those chain complexes \( A_\ast \) such that the homology objects \( H_n(A) \in A \) vanish for \( n < 0 \), and define \( \mathcal{D}^-_{\leq 0}(A) \) similarly. Then the pair \( (\mathcal{D}^-_{\geq 0}(A), \mathcal{D}^-_{\leq 0}(A)) \) determines a t-structure on \( \mathcal{D}^-(A) \). Moreover, the heart of \( \mathcal{D}^-(A) \) is canonically equivalent to (the nerve of) the abelian category \( A \).

**Lemma 1.3.2.20.** Let \( A \) be an abelian category, and let \( P_\ast \in \text{Ch}(A) \) be a complex of projective objects of \( A \) such that \( P_n \simeq 0 \) for \( n \ll 0 \). Let \( Q_\ast \to Q_\ast' \) be a quasi-isomorphism in \( \text{Ch}(A) \). Then the induced map

\[
\text{Map}_{\text{Ch}(A)}(P_\ast, Q_\ast) \to \text{Map}_{\text{Ch}(A)}(P_\ast, Q_\ast')
\]

is a quasi-isomorphism.

**Proof.** We observe that \( P_\ast \) is a homotopy colimit of its naive truncations

\[
\ldots \to 0 \to P_n \to P_{n-1} \to \ldots
\]

It therefore suffices to prove the result for each of these truncations, so we may assume that \( P_\ast \) is concentrated in finitely many degrees. Working by induction, we can reduce to the case where \( P_\ast \) is concentrated in a single degree. Shifting, we can reduce to the case where \( P_\ast \) consists of a single projective object \( P \) concentrated in degree zero. Since \( P \) is projective, we have isomorphisms

\[
H_i \text{Map}_{\text{Ch}(A)}(P_\ast, Q_\ast) \simeq \text{Hom}_A(P, H_i(Q_\ast)) \simeq \text{Hom}_A(P, H_i(Q_\ast')) \simeq \text{Map}_{\text{Ch}(A)}(P_\ast, Q_\ast').
\]

\[\square\]

**Lemma 1.3.2.21.** Let \( A \) be an abelian category. Suppose that \( P_\ast, Q_\ast \in \text{Ch}(A) \) have the following properties:

1. Each \( P_n \) is projective, and \( P_n \simeq 0 \) for \( n < 0 \).
2. The homologies \( H_n(Q_\ast) \) vanish for \( n > 0 \).

Then the space \( \text{Map}_{N_{dg}(\text{Ch}(A))}(P_\ast, Q_\ast) \) is discrete, and we have a canonical isomorphism of abelian groups

\[
\text{Ext}^0(P_\ast, Q_\ast) \simeq \text{Hom}_A(H_0(P_\ast), H_0(Q_\ast)).
\]

**Proof.** Let \( Q_\ast' \) be the complex

\[
\ldots \to 0 \to \text{coker}(Q_1 \to Q_0) \to Q_{-1} \to \ldots
\]

Condition (2) implies that the canonical map \( Q_\ast \to Q_\ast' \) is a quasi-isomorphism. In view of (1) and Lemma 1.3.2.20, it will suffice to prove the result after replacing \( Q_\ast \) by \( Q_\ast' \). In this case, we have

\[
\text{Map}_{\text{Ch}(A)}(P_\ast, Q_\ast)_m \simeq \begin{cases} 0 & \text{if } m > 0 \\ \text{Hom}_A(P_0, Q_0) & \text{if } m = 0. \end{cases}
\]

Unwinding the definitions, we see that \( H_0(\text{Map}_{\text{Ch}(A)}(P_\ast, Q_\ast)) \) is the subgroup of \( \text{Hom}_A(P_0, Q_0) \) given by \( \text{Hom}_A(\text{coker}(P_1 \to P_0), \ker(Q_0 \to Q_{-1})) \simeq \text{Hom}_A(H_0(P), H_0(Q)) \). The desired result now follows from Remark 1.3.1.12. \[\square\]
Proof of Proposition 1.3.2.19. We begin with the following observation:

(*) For any object \( A_n \in \text{Ch}(A) \), there exists a map \( f_n : P_n \to A_n \) where each \( P_n \) is projective, \( P_n \simeq 0 \) for \( n < 0 \), and the induced map \( H_k(P_n) \to H_k(A_n) \) is an isomorphism for \( k \geq 0 \).

To prove (*), we construct projective objects \( P_n \in A \), differentials \( d_n : P_n \to P_{n-1} \), and maps \( f_n : P_n \to A_n \) which are compatible with the differentials, using induction on \( n \). For \( n < 0 \) set \( P_n = 0 \) (so that \( f_n \) and \( d_n \) are uniquely determined). Suppose that \( n \geq 0 \) and that \( P_{n-1}, d_{n-1}, \) and \( f_{n-1} \) have already been defined. Since \( A \) has enough projective objects, we can choose a projective object \( P_n \) equipped with an epimorphism

\[ g : P_n \to A_n \times_{\ker(A_{n-1} \to A_{n-2})} \ker(P_{n-1} \to P_{n-2}). \]

We now define \( f_n : P_n \to A_n \) to be the composition of \( g \) with the projection onto the first factor, and \( d_n : P_n \to P_{n-1} \) to be the composition of \( g \) with the projection onto the second factor (followed by the inclusion of \( \ker(P_{n-1} \to P_{n-2}) \) into \( P_{n-1} \)). It is easy to see that this construction yields a map of chain complexes \( f : P_* \to A_* \) with the desired properties. Note also that if \( A_* \in \mathcal{D}^{-}(A) \) and the homologies \( H_n(A_\bullet) \) vanish for \( n < 0 \), then \( f \) is a quasi-isomorphism between projective complexes and therefore a chain homotopy equivalence.

It is clear that \( \mathcal{D}_{\geq 0}(A)[{-1}] \subseteq \mathcal{D}_{\geq 0}(A) \) and \( \mathcal{D}_{\geq 0}(A)[{-1}] \subseteq \mathcal{D}_{0}(A) \). Suppose now that \( A_* \in \mathcal{D}_{0}(A) \) and \( B_* \in \mathcal{D}_{0}(A) \); we wish to show that \( \text{Ext}^{0}_{\mathcal{D}^{-}(A)}(A_\bullet, B_\bullet) \simeq 0 \). Using (*), we may reduce to the case where \( A_n \simeq 0 \) for \( n < 0 \). The desired result now follows immediately from Lemma 1.3.2.21. Finally, choose an arbitrary object \( A_* \in \mathcal{D}^{-}(A) \), and let \( f : P_* \to A_* \) be as in (*). Using the construction of cofibers given in the proof of Proposition 1.3.2.10, we deduce that \( \text{cofib}(f)[{-1}] \subseteq \mathcal{D}_{\leq 0}(A) \). This completes the proof that \( (\mathcal{D}_{\geq 0}(A), \mathcal{D}_{\leq 0}(A)) \) is a t-structure on \( \mathcal{D}^{-}(A) \).

It remains to describe the heart of the stable \( \infty \)-category \( \mathcal{D}^{-}(A) \). Note that the construction \( A_* \mapsto H_0(A_\bullet) \) determines a functor \( \theta : N_{dg}(\text{Ch}(A)) \to N(A) \). Let \( \mathcal{C} \subseteq N_{dg}(\text{Ch}(A)) \) be the full subcategory spanned by complexes \( P_* \) such that each \( P_n \) is projective, \( P_n \simeq 0 \) for \( n < 0 \), and \( H_n(P_\bullet) \simeq 0 \) for \( n \neq 0 \). Assertion (*) implies that the inclusion \( \mathcal{C} \subseteq \mathcal{D}^{-}(A) \) is an equivalence of \( \infty \)-categories. Lemma 1.3.2.21 implies that \( \theta | \mathcal{C} \) is fully faithful. Finally, we can apply (*) in the case where \( A_* \) is concentrated in degree zero to deduce that \( \theta | \mathcal{C} \) is essentially surjective. It follows that \( \theta \) restricts to an equivalence \( \mathcal{D}^{-}(A)^\mathcal{C} \to N(A) \).

If \( A \) is an abelian category with enough projective objects, then the full subcategory \( \mathcal{D}_{\geq 0}(A) \subseteq \mathcal{D}^{-}(A) \) admits an alternative description by means of the Dold-Kan correspondence. Note first that for any additive category \( \mathcal{B} \), the category of simplicial objects \( \text{Fun}(\Delta^{op}, \mathcal{B}) \) is naturally tensored over the category of finite simplicial sets: the tensor product of a simplicial object \( P_\bullet \) with a simplicial set \( K \) is given by \( [n] \mapsto (\mathbb{Z}K_n) \otimes P_n \). We may therefore view \( \text{Fun}(\Delta^{op}, \mathcal{B}) \) as a simplicial category, whose mapping spaces are characterized by the formula

\[
\text{Hom}_{\text{Set}_{\Delta}}(K, \text{Map}_{\text{Fun}(\Delta^{op}, \mathcal{B})}(P_\bullet, P'_\bullet)) \simeq \text{Hom}_{\text{Fun}(\Delta^{op}, \mathcal{B})}(\mathbb{Z}K_\bullet \otimes P_\bullet, P'_\bullet)
\]

for every finite simplicial set \( K \). The following result will play an important role in §1.3.3:

Proposition 1.3.2.22. Let \( A \) be an abelian category with enough projective objects and let \( A_{\text{proj}} \) denote the full subcategory of \( A \) spanned by the projective objects. Then \( \mathcal{D}_{\geq 0}(A) \) is equivalent to the underlying \( \infty \)-category of the simplicial category \( \text{Fun}(\Delta^{op}, A_{\text{proj}}) \).

The proof of Proposition 1.3.2.22 will require some preliminary remarks. Suppose that \( A \) is an idempotent complete additive category, so that the Dold-Kan correspondence supplies an equivalence of categories \( \text{DK} : \text{Ch}(A)_{\geq 0} \to \text{Fun}(\Delta^{op}, A) \) (Theorem 1.2.3.7). For every pair of chain complexes \( M_\bullet, M'_\bullet \in \text{Ch}(A)_{\geq 0} \) and any finite simplicial set \( K \), a morphism of simplicial sets \( \phi : K \to \text{Map}_{\text{Ch}(A)}(M_\bullet, M'_\bullet) \) determines a composite
map
\[
\mathbb{Z}K \otimes \text{DK}_\bullet M \simeq (\text{DK}_\bullet \circ N_\bullet)(\mathbb{Z}K \otimes \text{DK}_\bullet (M))
\]
\[
\xrightarrow{\text{AW}} \text{DK}_\bullet(N_\bullet(K) \otimes N_\bullet \text{DK}_\bullet(M)) \simeq \text{DK}_\bullet(N_\bullet K \otimes M_\bullet)
\]
here AW denotes the Alexander-Whitney map of Construction 1.2.3.22. This construction is natural in \( K \).

HOMOLOGICAL ALGEBRA AND DERIVED CATEGORIES

Using the associativity properties of the Alexander-Whitney construction (Remark 1.2.3.25), we see that these maps are compatible with composition and therefore endow \( \text{DK} : \text{Ch}(A) \to \text{Fun}(\Delta^{op}, A) \) with the structure of a simplicial functor (where we view \( \text{Ch}(A) \) as a simplicial category using Construction 1.3.1.13). Although \( \text{DK} \) is an equivalence of ordinary categories, it is not an equivalence of simplicial categories, because the Alexander-Whitney maps are not isomorphisms. Nevertheless, we have the following result:

**Proposition 1.3.2.23.** Let \( A \) be an idempotent complete additive category. Then the functor
\[
\text{DK} : \text{Ch}(A)_{\geq 0} \to \text{Fun}(\Delta^{op}, A)
\]
is a weak equivalence of simplicial categories.

**Proof.** Since Theorem 1.2.3.7 implies that \( \text{DK} \) is essentially surjective, it will suffice to show that for every pair of chain complexes \( P_\bullet, Q_\bullet \in \text{Ch}(A)_{\geq 0} \), the map
\[
\theta_P : \text{Map}_{\text{Ch}(A)_A}(P_\bullet, Q_\bullet) \to \text{Map}_{\text{Fun}(\Delta^{op}, A)}(\text{DK}_\bullet(P_\bullet), \text{DK}_\bullet(Q_\bullet))
\]
is a weak homotopy equivalence. In the argument which follows, we will regard \( Q_\bullet \) as fixed. For each object \( A \in \mathcal{A} \), let \( A[n] \in \text{Ch}(A) \) denote the chain complex consisting of the single object \( A \), concentrated in degree \( n \). Let us say that a chain complex \( M_\bullet \) is *good* if the map \( \theta_M \) is a weak homotopy equivalence. We now proceed as follows:

1. Let \( A \) be an object of \( \mathcal{A} \). For any simplicial set \( K \), the Alexander-Whitney map \( \text{AW} : N_\bullet(K) \otimes \text{DK}(A[0]) \to N_\bullet(K) \otimes A[0] \) is an isomorphism of chain complexes. It follows that \( A[0] \) is good; in fact, the map \( \theta_{A[0]} \) is an isomorphism of simplicial sets. In particular, the simplicial set \( X = \text{Map}_{\text{Fun}(\Delta^{op}, \mathcal{A})}(\text{DK}_\bullet(A[0]), \text{DK}_\bullet(Q)) \) is a Kan complex.

2. Let \( A \) be an object of \( \mathcal{A} \) and \( n > 0 \). Then the map
\[
\text{Map}_{\text{Fun}(\Delta^{op}, \mathcal{A})}(\mathbb{Z} \Delta^n \otimes \text{DK}_\bullet(A[0]), \text{DK}_\bullet(Q)) \simeq \text{Fun}(\Delta^n, X) \to \text{Fun}(\Lambda^n_0, X)
\]
\[
\simeq \text{Map}_{\text{Fun}(\Delta^{op}, \mathcal{A})}(\mathbb{Z} \Lambda^n_0 \otimes \text{DK}_\bullet(A[0]), \text{DK}_\bullet(Q))
\]
is a trivial Kan fibration. Let \( E(n)_\bullet \) be defined as in the proof of Proposition 1.3.2.11, so that we have an isomorphism of simplicial abelian groups \( N_\bullet(\Delta^n) \simeq N_\bullet(\Lambda^n_0) \otimes E(n)_\bullet \). We conclude that the mapping space \( \text{Map}_{\text{Fun}(\Delta^{op}, \mathcal{A})}(\text{DK}(E(n) \otimes A[0]), \text{DK}(M_\bullet)) \) is a contractible Kan complex. Since the zero map from \( E(n)_\bullet \otimes A[0] \) to itself is chain homotopic to the identity, we conclude also that \( \text{Map}_{\text{Ch}(A)}(E(n)_\bullet \otimes A[0], M_\bullet) \) is a contractible Kan complex. In particular, \( E(n)_\bullet \otimes A[0] \) is good.
(3) Let \( n \geq 1 \), and regard \( \mathbb{Z}[n-1] \) as a subcomplex of \( E(n)_* \). A choice of isomorphism \( N_n(\Delta^n) \cong \mathbb{Z} \cong E(n)_* \) extends uniquely to a map of chain complexes \( N_n(\Delta^n) \to E(n)_* \), which fits into a pushout diagram

\[
\begin{array}{ccc}
N_*(\partial \Delta^n) & \longrightarrow & N_*(\Delta^n) \\
\downarrow & & \downarrow \\
\mathbb{Z}[n-1] & \longrightarrow & E(n)_*.
\end{array}
\]

It follows that for any \( A \in \mathcal{A} \), the induced map

\[
\text{Map}_{\text{Fun}(\Delta^{op}, \mathcal{A})}(\text{DK}_*(E(n) \otimes A), \text{DK}_*(Q)) \to \text{Map}_{\text{Fun}(\Delta^{op}, \mathcal{A})}(\text{DK}_*(A[n-1]), \text{DK}_*(Q))
\]

is a pullback of the map \( \text{Fun}(\Delta^n, X) \to \text{Fun}(\partial \Delta^n, X) \), and therefore a Kan fibration.

(4) Let \( P_* \in \text{Ch}(\mathcal{A})_{\geq 0} \), and suppose we are given an object \( A \in \mathcal{A} \) and a map \( A \to P_{n-1} \) for \( n > 0 \). Form a pushout diagram of chain complexes

\[
\begin{array}{ccc}
A[n-1] & \longrightarrow & E(n)_* \otimes A[0] \\
\downarrow & & \downarrow \\
P_* & \longrightarrow & P'_*.
\end{array}
\]

We obtain diagrams of mapping spaces

\[
\begin{array}{ccc}
\text{Map}_{\text{Ch}(\mathcal{A})_\Delta}(P'_*, Q_*) & \longrightarrow & \text{Map}_{\text{Ch}(\mathcal{A})_\Delta}(P_*, Q_*) \\
\downarrow & & \downarrow \\
\text{Map}_{\text{Ch}(\mathcal{A})_\Delta}(E(n)_* \otimes A[0], Q_*) & \longrightarrow & \text{Map}_{\text{Ch}(\mathcal{A})_\Delta}(A[n-1], Q_*)
\end{array}
\]

\[
\begin{array}{ccc}
\text{Map}_{\text{Fun}(\Delta^{op}, \mathcal{A})}(\text{DK}(P'), \text{DK}(Q)) & \longrightarrow & \text{Map}_{\text{Fun}(\Delta^{op}, \mathcal{A})}(\text{DK}(P), \text{DK}(Q)) \\
\downarrow & & \downarrow \\
\text{Map}_{\text{Fun}(\Delta^{op}, \mathcal{A})}(\text{DK}(E(n)_* \otimes A[0]), \text{DK}(Q)) & \longrightarrow & \text{Map}_{\text{Fun}(\Delta^{op}, \mathcal{A})}(\text{DK}(A[n-1]), \text{DK}(Q)).
\end{array}
\]

The first diagram is a homotopy pullback square by Corollary 1.3.2.16, and the second diagram is a homotopy pullback square by (3). Since \( E(n)_* \otimes A[0] \) is good by (2), we conclude that if \( P_* \) and \( A[n-1] \) are good, then \( P'_* \) is also good.

(5) Taking \( P_* = 0 \) in (4), we conclude that if \( A[n-1] \) is good then \( A[n] \) is good. Combining this with (1), we deduce that each \( A[n] \) is good using induction on \( n \).

(6) Let \( P_* \) be arbitrary. For each \( n \geq 0 \), let \( P(n)_* \) be the chain complex

\[
\cdots \to 0 \to P_n \to P_{n-1} \to \cdots \to P_0 \to 0 \to \cdots
\]

We have an evident pushout diagram

\[
\begin{array}{ccc}
P_n[n-1] & \longrightarrow & E(n)_* \otimes P_n \\
\downarrow & & \downarrow \\
P(n-1)_* & \longrightarrow & P(n)_*.
\end{array}
\]

Using (4) and (5), we conclude that each \( P(n)_* \) is good using induction on \( n \). Then \( \theta_P \) is the homotopy limit of a tower of homotopy equivalences \( \{\theta_{P^n}\} \). It follows that \( \theta_P \) is itself a homotopy equivalence: that is, \( P_* \) is good.
Remark 1.3.2.24. Let \( \mathcal{A} \) be an arbitrary additive category. Then \( \mathcal{A} \) admits a fully faithful embedding into an idempotent complete additive category. It follows from Proposition 1.3.2.23 that the functor \( \text{DK} : \text{Ch}(\mathcal{A})_{\geq 0} \to \text{Fun}(\Delta^{\text{op}}, \mathcal{A}) \) induces a fully faithful embedding of \( \infty \)-categories \( N(\text{Ch}(\mathcal{A})_{\geq 0}) \to N(\text{Fun}(\Delta^{\text{op}}, \mathcal{A})) \).

Proof of Proposition 1.3.2.22. Let \( \mathcal{A} \) be an abelian category with enough projective objects. If \( P_* \) is an object of \( D_{\geq 0}(\mathcal{A}) \), then assertion (+) appearing in the proof of Proposition 1.3.2.19 guarantees the existence of a quasi-isomorphism \( P'_* \to P_* \), where \( P'_* \in \text{Ch}(\mathcal{A}_{\text{proj}})_{\geq 0} \). Such a map is automatically a chain homotopy equivalence, and therefore an equivalence in the \( \infty \)-category \( D_{\geq 0}(\mathcal{A}) \). It follows that the inclusion \( N_{dg}(\text{Ch}(\mathcal{A}_{\text{proj}})_{\geq 0}) \to D_{\geq 0}(\mathcal{A}) \) is an equivalence of \( \infty \)-categories. Combining this observation with Propositions 1.3.2.23 and 1.3.1.17, we obtain equivalences

\[
D_{\geq 0}(\mathcal{A}) \leftrightarrow N_{dg}(\text{Ch}(\mathcal{A}_{\text{proj}})_{\geq 0}) \leftrightarrow N(\text{Ch}(\mathcal{A}_{\text{proj}})_{\geq 0}) \to N(\text{Fun}(\Delta^{\text{op}}, \mathcal{A}_{\text{proj}})).
\]

\( \square \)

1.3. The Universal Property of \( D^-(\mathcal{A}) \)

Let \( \mathcal{A} \) be an abelian category with enough projective objects. In §1.3.2, we introduced the derived \( \infty \)-category \( D^-(\mathcal{A}) \), whose objects are right-bounded chain complexes of projective objects of \( \mathcal{A} \). Our goal in this section is to characterize the \( \infty \)-category \( D^-(\mathcal{A}) \) by a universal mapping property. To formulate this property, we need to introduce a bit of terminology.

Definition 1.3.3.1. Let \( \mathcal{C} \) and \( \mathcal{C}' \) be stable \( \infty \)-categories equipped with t-structures. We will say that a functor \( f : \mathcal{C} \to \mathcal{C}' \) is right t-exact if it is exact and carries \( \mathcal{C}_{\geq 0} \) into \( \mathcal{C}'_{\geq 0} \). We say that \( f \) is left t-exact if it is exact and carries \( \mathcal{C}_{\leq 0} \) into \( \mathcal{C}'_{\leq 0} \).

Our main result can now be stated as follows:

Theorem 1.3.3.2. Let \( \mathcal{A} \) be an abelian category with enough projective objects, let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a left complete t-structure, and let \( \mathcal{E} \subseteq \text{Fun}(D^-(\mathcal{A}), \mathcal{C}) \) be the full subcategory spanned by those right t-exact functors which carry projective objects of \( \mathcal{A} \) into the heart of \( \mathcal{C} \). The construction \( F \mapsto \tau_{\leq 0} \circ (F|D^-(\mathcal{A})^{\text{proj}}) \) determines an equivalence from \( \mathcal{E} \) to (the nerve of) the ordinary category of right exact functors from \( \mathcal{A} \) to the heart \( \mathcal{C}^{\text{proj}} \) of \( \mathcal{C} \).

Remark 1.3.3.3. Let \( \mathcal{A} \) be an abelian category with enough projective objects. We will prove below that the \( \infty \)-category \( D^-(\mathcal{A}) \) is left complete (with respect to the t-structure of Proposition 1.3.2.19); see Proposition 1.3.3.16. It follows that \( D^-(\mathcal{A}) \) is determined (up to canonical equivalence) by the universal property of Theorem 1.3.3.2.

If \( \mathcal{A} \) and \( \mathcal{C} \) are as in Theorem 1.3.3.2, then any right exact functor from \( \mathcal{A} \) to \( \mathcal{C}^{\text{proj}} \) can be extended (in an essentially unique way) to a functor \( D^-(\mathcal{A}) \to \mathcal{C} \). In particular, if the abelian category \( \mathcal{C}^{\text{proj}} \) has enough projective objects, then we obtain an induced map \( D^-(\mathcal{C}^{\text{proj}}) \to \mathcal{C} \).

Example 1.3.3.4. Let \( \mathcal{A} \) and \( \mathcal{B} \) be abelian categories equipped with enough projective objects. Then any right-exact functor \( f : \mathcal{A} \to \mathcal{B} \) extends to a right t-exact functor \( F : D^-(\mathcal{A}) \to D^-(\mathcal{B}) \). One typically refers to \( F \) as the left derived functor of \( f \).

Example 1.3.3.5. Let \( \text{Sp} \) be the stable \( \infty \)-category of spectra (see §1.4.3), with its natural t-structure. Then the heart of \( \text{Sp} \) is equivalent to the category \( \mathcal{A} \) of abelian groups. We therefore obtain a functor \( D^-(\mathcal{A}) \to \text{Sp} \), which carries a complex of abelian groups to the corresponding generalized Eilenberg-MacLane spectrum.
Remark 1.3.3.6. Let \( \mathcal{A} \) be an abelian category with enough projective objects, let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a left complete t-structure, and let \( F : \mathcal{D}^-(\mathcal{A}) \to \mathcal{C} \) be a right t-exact functor which carries projective objects of \( \mathcal{A} \) into the heart of \( \mathcal{C} \). Then the following conditions are equivalent:

(i) The functor \( F \) is left t-exact: that is, \( F \) carries \( \mathcal{D}^-(\mathcal{A}) \leq 0 \) into \( \mathcal{C} \leq 0 \).

(ii) The functor \( F \) carries \( \mathcal{N}(\mathcal{A}) \subseteq \mathcal{D}^-(\mathcal{A}) \) into the heart of \( \mathcal{C} \).

(iii) The underlying right-exact functor \( f : \mathcal{A} \to \mathcal{C}^\triangledown \) is exact.

The implication \((i) \Rightarrow (ii)\) is obvious. To prove that \((ii) \Rightarrow (i)\), we prove by induction on \( n \) that for every object \( A \in \mathcal{D}^-(\mathcal{A}) \leq 0 \cap \mathcal{D}^-(\mathcal{A}) \geq -n \), we have \( F(A) \in \mathcal{C} \leq 0 \). If \( n = 0 \), this follows from \((ii)\). More generally, we have a fiber sequence

\[
A' \to A \to A''
\]

where \( A' \in \mathcal{D}^-(\mathcal{A}) \leq 0 \cap \mathcal{D}^-(\mathcal{A}) \geq 1-n \) and \( A''[n] \in \mathcal{D}^-(\mathcal{A}) \leq N(\mathcal{A}) \). Then \( F(A') \in \mathcal{C} \leq 0 \) by the inductive hypothesis, and \( F(A'') = F(A''[n])[-n] \in \mathcal{C} \leq -n \subseteq \mathcal{C} \leq 0 \) by virtue of \((i)\), so that \( F(A) \in \mathcal{C} \leq 0 \).

To prove \((ii) \Rightarrow (iii)\), we note that every short exact sequence

\[
0 \to A' \to A \to A'' \to 0
\]

in \( \mathcal{A} \) gives rise to a fiber sequence

\[
F(A') \to F(A) \to F(A'')
\]

in \( \mathcal{C} \leq 0 \), hence a short exact sequence

\[
\pi_1 F(A'') \to f(A') \overset{\phi}{\to} f(A) \to f(A'') \to 0
\]

in the abelian category \( \text{h} \mathcal{C}^\triangledown \). If \((ii)\) is satisfied, then \( \pi_1 F(A'') \simeq 0 \), so that the map \( \phi \) is injective.

It remains to prove that \((iii)\) implies \((ii)\). Assume that \((iii)\) is satisfied. Using induction on \( n > 0 \), we prove that for each \( A \in \mathcal{A} \), the object \( \pi_n F(A) \in \mathcal{C}^\triangledown \) vanishes. Since \( \mathcal{C} \) is left-complete, this will guarantee that \( \tau_{>1} F(A) \) vanishes, so that \( F(A) \) belongs to the heart of \( \mathcal{C} \). To carry out the induction, we choose a short exact sequence

\[
0 \to A' \xrightarrow{f} P \xrightarrow{A} 0
\]

in the abelian category \( \mathcal{A} \), where \( P \) is projective, so that we have an exact sequence

\[
\pi_n F(P) \to \pi_n F(A) \to \pi_{n-1} F(A') \to \pi_{n-1} F(P).
\]

If \( n > 1 \), then \( \pi_n F(P) \simeq \pi_{n-1} F(P) \simeq 0 \), so that \( \pi_n F(A) \simeq \pi_{n-1} A' \) vanishes by the inductive hypothesis. If \( n = 1 \), then \( \pi_n F(P) \) vanishes so that \( \pi_n F(A) \) can be identified with the kernel of the map \( f(\psi) : \pi_0 F(A') \to \pi_0 F(P) \). If the functor \( f \) is exact, then \( f(\psi) \) is a monomorphism so that \( \pi_n F(A) \simeq 0 \).

We have the following recognition criterion for derived categories:

Proposition 1.3.3.7. Let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a left complete t-structure. Suppose that the abelian category \( \mathcal{A} = \text{h} \mathcal{C}^\triangledown \) has enough projective objects. Then there exists an essentially unique t-exact functor \( F : \mathcal{D}^-(\mathcal{A}) \to \mathcal{C} \) extending the inclusion \( f : \mathcal{N}(\mathcal{A}) \simeq \mathcal{C}^\triangledown \subseteq \mathcal{C} \). Moreover, the following conditions are equivalent:

(i) The functor \( F \) is fully faithful.

(ii) For every pair of objects \( X, Y \in \mathcal{A} \), if \( X \) is projective, then the abelian groups \( \text{Ext}^i_{\mathcal{C}}(X, Y) \) vanish for \( i > 0 \).

(iii) For every pair of objects \( X, Y \in \mathcal{A} \), if \( X \) is projective, then there exists a monomorphism \( Y \to Z \) such that the abelian groups \( \text{Ext}^i_{\mathcal{C}}(X, Z) \) vanish for \( i > 0 \).
Moreover, if these conditions are satisfied, then the essential image of $F$ is the full subcategory $\bigcup_n \mathbb{C}_{\geq -n}$ of right-bounded objects of $\mathbb{C}$.

Proof. The existence of $F$ follows from Theorem 1.3.3.2 and Remark 1.3.3.6. The implications $(i) \Rightarrow (ii) \Rightarrow (iii)$ are obvious. We prove that $(iii) \Rightarrow (ii)$ by induction on $i > 0$. Assume that $X, Y \in A$ where $X$ is projective, and choose a monomorphism $\theta_{X,Y} : \text{Map}_A(X, Y) \to \text{Map}_A(FX, FY)$.

Since $X$ is a projective object of $A$, this map is a surjection, so that $\text{Ext}_A^0(X, Y)$ vanishes as required.

We now prove that $(ii)$ implies $(i)$. Choose any pair of objects $X, Y \in D^-(A)$; we wish to prove that $F$ induces a homotopy equivalence

$$
\theta_{X,Y} : \text{Map}_{D^-(A)}(X, Y) \to \text{Map}_A(FX, FY).
$$

Since $D^-(A)$ and $\mathbb{C}$ are both left-complete (see Proposition 1.3.3.16), both sides can be identified with a homotopy limit of the tower of maps

$$
\text{Map}_{D^-(A)}(\tau_{\leq n} X, \tau_{\leq n} Y) \to \text{Map}_A(F\tau_{\leq n} X, F\tau_{\leq n} Y).
$$

It therefore suffices to show that each of these maps is a homotopy equivalence. We may therefore replace $Y$ by $\tau_{\leq n} Y$ and thereby reduce to the case where $Y$ belongs to the full subcategory $D^b(A) = \bigcup_n D^-(A)_{\leq n}$ spanned by the (homologically) bounded objects of $D^-(A)$.

Let $D'$ denote the full subcategory of $D^b(A)$ spanned by those objects $Y$ for which the map $\theta_{X,Y}$ is a homotopy equivalence, for every object $X \in D^-(A)$. We wish to prove that $D' = D^b(A)$. Since $D'$ is stable under translations and extensions in $D^b(A)$, it will suffice to show that $D'$ contains the heart of $D^b(A)$. We may therefore reduce to the case where $Y$ is in the heart of $D^-(A)$.

The object $X$ can be represented by a chain complex of projective objects

$$
\cdots \to P_2 \to P_1 \to P_0 \to P_{-1} \to P_{-2} \to \cdots
$$

in the abelian category $A$. Let $X'$ denote the truncated chain complex

$$
\cdots \to 0 \to P_1 \to P_0 \to P_{-1} \to P_{-2} \to \cdots,
$$

so that we have a fiber sequence

$$
X' \to X \to X''
$$

in $D^-(A)$ with $X'' \in \mathbb{C}_{\geq 2}$. We have a commutative diagram

$$
\begin{array}{ccc}
\text{Map}_{D^-(A)}(X, Y) & \xrightarrow{\theta_{X,Y}} & \text{Map}_A(FX, FY) \\
\downarrow & & \downarrow \\
\text{Map}_{D^-(A)}(X', Y) & \xrightarrow{\theta_{X',Y}} & \text{Map}_A(FX', FY)
\end{array}
$$

where the vertical maps are homotopy equivalences. Consequently, to prove that $\theta_{X,Y}$ is a homotopy equivalence, it suffices to show that $\theta_{X',Y}$ is a homotopy equivalence. We may therefore replace $X$ by $X'$ and thereby reduce to the case where $X$ belongs to the full subcategory $\mathbb{E} \subseteq D^-(A)$ spanned by finite-length chain complexes of projective objects. Let $\mathbb{E}' \subseteq \mathbb{E}$ be the full subcategory spanned by those objects $X$ for
which the functor $F$ induces an isomorphism of abelian groups $\text{Ext}^n_{\mathcal{D}^{-}}(A,Y) \to \text{Ext}^n_{\mathcal{C}}(FX, FY)$ for every integer $n$. We wish to prove that $\mathcal{E}' = \mathcal{E}$. Since $\mathcal{E}'$ is stable under extensions and translations, it will suffice to show that $\mathcal{E}'$ contains every projective object of $\mathcal{A}$. In other words, we must show that if $X, Y \in \mathcal{A}$ and $X$ is projective, then $F$ induces an isomorphism

$$\text{Ext}^n_{\mathcal{D}^{-}}(A,Y) \to \text{Ext}^n_{\mathcal{C}}(FX, FY).$$

If $n < 0$, then both sides vanish; if $n = 0$, then both sides can be identified with $\text{Hom}_A(X,Y)$. If $n > 0$, then the left side vanishes since $X$ is projective, and the right side vanishes by virtue of assumption (ii).

We now complete the proof by describing the essential image of $F$. Replacing $\mathcal{C}$ by $\bigcup_n \mathcal{C}_{\geq -n}$, we may assume that $\mathcal{C}$ is right-bounded; we wish to prove that $F$ is an equivalence. Since $\mathcal{D}^{-}(\mathcal{A})$ and $\mathcal{C}$ are both left-complete, we can identify $F$ with a homotopy limit of a tower of fully faithful functors $\{F_n : \mathcal{D}^{-}(\mathcal{A})_{\leq n} \to \mathcal{C}_{\leq n}\}_{n \geq 0}$; it will therefore suffice to show that each $F_n$ is an equivalence of $\infty$-categories. Each of the functors $F_n$ is a restriction of $F$, and therefore fully faithful. It therefore suffices to show that each $F_n$ is essentially surjective. Let $C$ be an object of $\mathcal{C}_{\leq n}$. Since $\mathcal{C}$ is right-bounded, we may suppose that $C \in \mathcal{C}_{\geq m}$, for some integer $m$. We will prove that $C$ belongs to the essential image of $F_n$ using descending induction on $m$. If $m > n$, then $C \simeq 0$ and the result is obvious. Otherwise, we choose a distinguished triangle

$$C' \to C \to C''[m] \xrightarrow{\alpha} C'[1]$$

where $C' \in \mathcal{C}_{\geq m+1}$ and $C'' \in \mathcal{C}_{\geq 0}$; note that $C'$ and $C''[m]$ both belong to $\mathcal{C}_{\leq n}$. The inductive hypothesis guarantees that $C' \simeq F(X)$ for some object $X \in \mathcal{D}^{-}(\mathcal{A})_{\leq n}$, and we can identify $C''$ with an object $A$ of the abelian category $\mathcal{A}$. Since $F$ is fully faithful, the map $\alpha$ is represented by a morphism $\beta : A[m] \to X[1]$ in $\mathcal{D}^{-}(\mathcal{A})$. Let $Y = \text{fib}(\beta)$, so that we have a fiber sequence

$$X \to Y \to A[m]$$

which proves that $Y \in \mathcal{D}^{-}(\mathcal{A})_{\leq n}$. Since $F$ is exact, we deduce that $FY \simeq \text{fib}(F(\beta)) \simeq C$, so that $C$ belongs to the essential image of $F_n$ as required.

We will deduce Theorem 1.3.3.2 from the following more precise characterization of the $\infty$-category $\mathcal{D}^{-}_{\geq 0}(\mathcal{A})$:

**Theorem 1.3.3.8.** Let $\mathcal{A}$ be an abelian category with enough projective objects, $\mathcal{A}_{\text{proj}} \subseteq \mathcal{A}$ the full subcategory spanned by the projective objects, and $\mathcal{C}$ an arbitrary $\infty$-category which admits geometric realizations of simplicial objects. Let $\text{Fun}'(\mathcal{D}^{-}_{\geq 0}(\mathcal{A}), \mathcal{C})$ denote the full subcategory of $\text{Fun}(\mathcal{D}^{-}_{\geq 0}(\mathcal{A}), \mathcal{C})$ spanned by those functors which preserve geometric realizations of simplicial objects. Then:

1. The restriction functor $\text{Fun}'(\mathcal{D}^{-}_{\geq 0}(\mathcal{A}), \mathcal{C}) \to \text{Fun}(\text{N}(\mathcal{A}_{\text{proj}}), \mathcal{C})$ is an equivalence of $\infty$-categories.

2. A functor $F \in \text{Fun}'(\mathcal{D}^{-}_{\geq 0}(\mathcal{A}), \mathcal{C})$ preserves preserves finite coproducts if and only if the restriction $F|\text{N}(\mathcal{A}_{\text{proj}})$ preserves finite coproducts.

Let us assume Theorem 1.3.3.8 for the moment, and explain how to use it to deduce Theorem 1.3.3.2. The proof of Theorem 1.3.3.8 itself will be given at the end of this section.

**Lemma 1.3.3.9.** Let $\mathcal{A}$ be an abelian category with enough projective objects, and let $\mathcal{B}$ be an arbitrary category which admits finite colimits. Let $\mathcal{C}$ be the category of right exact functors from $\mathcal{A}$ to $\mathcal{B}$, and let $\mathcal{C}'$ be the category of functors from $\mathcal{A}_{\text{proj}}$ to $\mathcal{B}$ which preserve finite coproducts (here $\mathcal{A}_{\text{proj}}$ denotes the full subcategory of $\mathcal{A}$ spanned by the projective objects). Then the restriction functor $\theta : \mathcal{C} \to \mathcal{C}'$ is an equivalence of categories.

**Proof.** We will give an explicit construction of an inverse functor. Let $f : \mathcal{A}_{\text{proj}} \to \mathcal{B}$ be a functor which preserves finite coproducts. Let $A \in \mathcal{A}$ be an arbitrary object. Since $\mathcal{A}$ has enough projectives, there exists a projective resolution

$$\cdots \to P_1 \xrightarrow{u} P_0 \to A \to 0.$$
We now define $F(A)$ to be the coequalizer of the map

$$f(P_1) \xrightarrow{f(0)} f(P_0).$$

Of course, this definition appears to depend not only on $A$ but on a choice of projective resolution. However, because any two projective resolutions of $A$ are chain homotopy equivalent to one another, $F(A)$ is well-defined up to canonical isomorphism. It is easy to see that $F : A \to D$ is a right exact functor which extends $f$, and that $F$ is uniquely determined (up to unique isomorphism) by these properties.

**Lemma 1.3.3.10.** (1) Let $\mathcal{C}$ be an $\infty$-category which admits finite coproducts and geometric realizations of simplicial objects. Then $\mathcal{C}$ admits all finite colimits. Conversely, if $\mathcal{C}$ is an $n$-category which admits finite colimits, then $\mathcal{C}$ admits geometric realizations of simplicial objects.

(2) Let $F : \mathcal{C} \to \mathcal{D}$ be a functor between $\infty$-categories which admit finite coproducts and geometric realizations of simplicial objects. If $F$ preserves finite coproducts and geometric realizations of simplicial objects, then $F$ is right exact. The converse holds if $\mathcal{C}$ and $\mathcal{D}$ are $n$-categories.

**Proof.** We will prove (1); the proof of (2) follows by the same argument. Now suppose that $\mathcal{C}$ admits finite coproducts and geometric realizations of simplicial objects. We wish to show that $\mathcal{C}$ admits all finite colimits. According to Proposition T.4.4.3.2, it will suffice to show that $\mathcal{C}$ admits coequalizers. Let $\Delta_{\leq 1}$ be the subcategory of $\Delta$ spanned by the objects $[0]$ and $[1]$ and injective maps between them, so that a coequalizer diagram in $\mathcal{C}$ can be identified with a functor $N(\Delta_{\leq 1})^{\text{op}} \to \mathcal{C}$. Let $j : N(\Delta_{\leq 1})^{\text{op}} \to N(\Delta)^{\text{op}}$ be the inclusion functor. We claim that every diagram $f : N(\Delta_{\leq 1})^{\text{op}} \to \mathcal{C}$ has a left Kan extension along $j$. To prove this, it suffices to show that for each $n \geq 0$, the associated diagram

$$N(\Delta_{\leq 1})^{\text{op}} \times N(\Delta)^{\text{op}} (N(\Delta_n)^{\text{op}}) \to \mathcal{C}$$

has a colimit. We now observe that this last colimit is equivalent to a coproduct: more precisely, we have $(j_! f)([n]) \simeq f([0]) \coprod f([1]) \coprod \ldots \coprod f([1])$, where there are precisely $n$ summands equivalent to $f([1])$. Since $\mathcal{C}$ admits finite coproducts, the desired Kan extension $j_! f$ exists. We now observe that $\lim (f)$ can be identified with $\lim (j_! f)$, and the latter exists in virtue of our assumption that $\mathcal{C}$ admits geometric realizations for simplicial objects.

Now suppose that $\mathcal{C}$ is an $n$-category which admits finite colimits; we wish to show that $\mathcal{C}$ admits geometric realizations. Passing to a larger universe if necessary, we may suppose that $\mathcal{C}$ is small. Let $\mathcal{D} = \text{Ind}(\mathcal{C})$, and let $\mathcal{C}' \subseteq \mathcal{D}$ denote the essential image of the Yoneda embedding $j : \mathcal{C} \to \mathcal{D}$. Then $\mathcal{D}$ admits small colimits (Theorem T.5.5.1.1) and $j$ is fully faithful (Proposition T.5.1.3.1); it will therefore suffice to show that $\mathcal{C}'$ is stable under geometric realization of simplicial objects in $\mathcal{D}$.

Fix a simplicial object $U_* : N(\Delta)^{\text{op}} \to \mathcal{C}' \subseteq \mathcal{D}$. Let $V_* : N(\Delta)^{\text{op}} \to \mathcal{D}$ be a left Kan extension of $U_* N(\Delta_{\leq n})^{\text{op}}$, and $\alpha_* : V_* \to U_*$ the induced map. The geometric realization of $V_*$ can be identified with the colimit of $U_* N(\Delta_{\leq n})^{\text{op}}$, and therefore belongs to $\mathcal{C}'$ since $\mathcal{C}'$ is stable under finite colimits in $\mathcal{D}$ (Proposition T.5.3.5.14). Consequently, it will suffice to prove that $\alpha_*$ induces an equivalence from the geometric realization of $V_*$ to the geometric realization of $U_*$. Let $L : \mathcal{P}(\mathcal{C}) \to \mathcal{D}$ be a left adjoint to the inclusion. Let $|U_*|$ and $|V_*|$ be colimits of $U_*$ and $V_*$ in the $\infty$-category $\mathcal{P}(\mathcal{C})$, and let $|\alpha_*| : |V_*| \to |U_*|$ be the induced map. We wish to show that $L|\alpha_*|$ is an equivalence in $\mathcal{D}$. Since $\mathcal{C}$ is an $n$-category, we have inclusions $\text{Ind}(\mathcal{C}) \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, \tau_{\leq n-1}) \subseteq \mathcal{P}(\mathcal{C})$. It follows that $L$ factors through the truncation functor $\tau_{\leq n-1} : \mathcal{P}(\mathcal{C}) \to \mathcal{P}(\mathcal{C})$. Consequently, it will suffice to prove that $\tau_{\leq n-1}|\alpha_*|$ is an equivalence in $\mathcal{P}(\mathcal{C})$. For this, it will suffice to show that the morphism $|\alpha_*|$ is $n$-connective (in the sense of Definition T.6.5.1.10). This follows from Lemma T.6.5.3.10, since $\alpha_k : V_k \to U_k$ is an equivalence for $k \leq n$.

**Lemma 1.3.3.11.** Let $\mathcal{C}$ and $\mathcal{C}'$ be stable $\infty$-categories equipped with $t$-structures. Let $\theta : \text{Fun}(\mathcal{C}, \mathcal{C}') \to \text{Fun}(\mathcal{C}_{\geq 0}, \mathcal{C}')$ be the restriction map. Then:
(1) If \( \mathcal{C} \) is right-bounded, then \( \theta \) induces an equivalence from the full subcategory of \( \text{Fun}(\mathcal{C}, \mathcal{C}') \) spanned by the right t-exact functors to the full subcategory of \( \text{Fun}(\mathcal{C}_{\geq 0}, \mathcal{C}'_{\geq 0}) \) spanned by the right exact functors.

(2) Let \( \mathcal{C} \) and \( \mathcal{C}' \) be left complete. Then the \( \infty \)-categories \( \mathcal{C}_{\geq 0} \) and \( \mathcal{C}'_{\geq 0} \) admit geometric realizations of simplicial objects. Furthermore, a functor \( F : \mathcal{C}_{\geq 0} \rightarrow \mathcal{C}'_{\geq 0} \) is right exact if and only if it preserves finite coproducts and geometric realizations of simplicial objects.

Proof. We first prove (1). If \( \mathcal{C} \) is right bounded, then \( \text{Fun}(\mathcal{C}, \mathcal{C}') \) is the (homotopy) inverse limit of the tower of \( \infty \)-categories

\[
\ldots \rightarrow \text{Fun}(\mathcal{C}_{\geq -1}, \mathcal{C}') \rightarrow \text{Fun}(\mathcal{C}_{\geq 0}, \mathcal{C}'),
\]

where the functors are given by restriction. The full subcategory of right t-exact functors is then given by the homotopy inverse limit

\[
\ldots \rightarrow \text{Fun}'(\mathcal{C}_{\geq -1}, \mathcal{C}'_{\geq -1}) \rightarrow \text{Fun}'(\mathcal{C}_{\geq 0}, \mathcal{C}')
\]

where \( \text{Fun}'(\mathcal{C}, \mathcal{D}) \) denotes the full subcategory of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \) spanned by the right exact functors. To complete the proof, it will suffice to show that this tower is essentially constant; in other words, that each \( \theta(n) \) is an equivalence of \( \infty \)-categories. Without loss of generality, we may suppose that \( n = 0 \). Choose shift functors on the \( \infty \)-categories \( \mathcal{C} \) and \( \mathcal{C}' \), and define

\[
\psi : \text{Fun}'(\mathcal{C}_{\geq 0}, \mathcal{C}'_{\geq 0}) \rightarrow \text{Fun}'(\mathcal{C}_{\geq -1}, \mathcal{C}'_{\geq -1})
\]

by the formula \( \psi(F) = \Sigma^{-1} \circ F \circ \Sigma \). We claim that \( \psi \) is a homotopy inverse to \( \theta(0) \). To prove this, we observe that the right exactness of \( F \in \text{Fun}'(\mathcal{C}_{\geq 0}, \mathcal{C}'_{\geq 0}) \), \( G \in \text{Fun}'(\mathcal{C}_{\geq -1}, \mathcal{C}'_{\geq -1}) \) determines canonical equivalences

\[
(\theta(0) \circ \psi)(F) \simeq F \quad (\psi \circ \theta(0))(G) \simeq G.
\]

We now prove (2). Since \( \mathcal{C} \) is left complete, \( \mathcal{C}_{\geq 0} \) is the (homotopy) inverse limit of the tower of \( \infty \)-categories \( \{\mathcal{C}_{\geq 0}\}_{\leq n} \) with transition maps given by right exact truncation functors. Lemma 1.3.3.10 implies that each \( \mathcal{C}_{\geq 0} \) admits geometric realizations of simplicial objects, and that each of the truncation functors preserves geometric realizations of simplicial objects. It follows that \( \mathcal{C}_{\geq 0} \) admits geometric realizations for simplicial objects. Similarly, \( \mathcal{C}'_{\geq 0} \) admits geometric realizations for simplicial objects.

If \( F \) preserves finite coproducts and geometric realizations of simplicial objects, then \( F \) is right exact (Lemma 1.3.3.10). Conversely, suppose that \( F \) is right exact; we wish to prove that \( F \) preserves geometric realizations of simplicial objects. It will suffice to show that each composition

\[
\mathcal{C}_{\geq 0} \xrightarrow{F} \mathcal{C}'_{\geq 0} \xrightarrow{\tau_{\leq n}} (\mathcal{C}'_{\geq 0})_{\leq n}
\]

preserves geometric realizations of simplicial objects. We observe that, in virtue of the right exactness of \( F \), this functor is equivalent to the composition

\[
\mathcal{C}_{\geq 0} \xrightarrow{\tau_{\leq n}} (\mathcal{C}_{\geq 0})_{\leq n} \xrightarrow{\tau_{\leq n} \circ F} (\mathcal{C}'_{\geq 0})_{\leq n}.
\]

It will therefore suffice to prove that \( \tau_{\leq n} \circ F \) preserves geometric realizations of simplicial objects, which follows from Lemma 1.3.3.10 since both the source and target are equivalent to \( n \)-categories. \( \square \)

Proposition 1.3.3.12. Let \( A \) be an abelian category with enough projective objects, and let \( \mathcal{C} \) be a stable \( \infty \)-category equipped with a left complete t-structure. Then the restriction functor

\[
\text{Fun}(\mathcal{D}^-(A), \mathcal{C}) \rightarrow \text{Fun}(\text{N}(A_{\text{proj}}), \mathcal{C})
\]

induces an equivalence from the full subcategory of \( \text{Fun}(\mathcal{D}^-(A), \mathcal{C}) \) spanned by the right t-exact functors to the full subcategory of \( \text{Fun}(\text{N}(A_{\text{proj}}), \mathcal{C}_{\geq 0}) \) spanned by functors which preserve finite coproducts (here \( A_{\text{proj}} \) denotes the full subcategory of \( A \) spanned by the projective objects).
Proof. Let \( \text{Fun}'(\mathcal{D}^-(A), \mathcal{C}) \) be the full subcategory of \( \text{Fun}(\mathcal{D}^-(A), \mathcal{C}) \) spanned by the right t-exact functors. Lemma 1.3.3.11 implies that \( \text{Fun}'(\mathcal{D}^-(A), \mathcal{C}) \) is equivalent (via restriction) to the full subcategory
\[
\text{Fun}'(\mathcal{D}^\geq_0(A), \mathcal{C}_\geq) \subseteq \text{Fun}(\mathcal{D}^\geq_0(A), \mathcal{C}_\geq)
\]
spanned by those functors which preserve finite coproducts and geometric realizations of simplicial objects. Theorem 1.3.3.8 allows us to identify \( \text{Fun}'(\mathcal{D}^\geq_0(A), \mathcal{C}_\geq) \) with the \( \infty \)-category of finite-coproduct preserving functors from \( N(A_{\text{proj}}) \) into \( \mathcal{C}_\geq \).

We now return to the proof of our main result.

Proof of Theorem 1.3.3.2. Proposition 1.3.3.12 implies that the restriction map \( \mathcal{E} \to \text{Fun}(N(A_{\text{proj}}), \mathcal{C}^\circ) \) is fully faithful, and that the essential image of \( \theta \) consists of the collection of coproduct-preserving functors from \( N(A_{\text{proj}}) \) to \( \mathcal{C}^\circ \). Lemma 1.3.3.9 allows us to identify the latter \( \infty \)-category with the nerve of the category of right exact functors from \( A \) to the heart of \( \mathcal{E} \).

We now turn to the proof of Theorem 1.3.3.8. Passing to a larger universe if necessary, we may assume without loss of generality that the abelian category \( A \) is small. We will analyze the \( \infty \)-category \( D^-(A) \geq_0 \) by embedding it into a larger \( \infty \)-category which admits sifted colimits. To this end, let \( A_{\text{proj}} \subseteq A \) denote the full subcategory of \( A \) spanned by the projective objects, and let \( A \) denote the category of product-preserving functors from \( A_{\text{proj}}^{\text{op}} \) to the category of simplicial sets, as in §T.5.5.9. Let \( A^\wedge \) denote the category of product-preserving functors from \( A_{\text{proj}}^{\text{op}} \) to sets, so that we can identify \( A \) with the category of simplicial objects of \( A^\wedge \). Our first goal is to understand the category \( A^\wedge \).

**Proposition 1.3.3.13.** Let \( A \) be a small abelian category with enough projective objects. Then:

1. The category \( A^\wedge \) can be identified with the category of Ind-objects of \( A \).
2. The category \( A^\wedge \) is abelian.
3. The abelian category \( A^\wedge \) has enough projective objects.

**Proof.** Assertion (1) follows immediately from Lemma 1.3.3.9 (taking \( B \) to be the opposite of the category of sets). Assertion (2) follows formally from (1) and the assumption that \( A \) is an abelian category (see, for example, [5]). We may identify \( A \) with a full subcategory of \( A^\wedge \) via the Yoneda embedding. Moreover, if \( P \) is a projective object of \( A \), then \( P \) is also projective when viewed as an object of \( A^\wedge \). An arbitrary object of \( A^\wedge \) can be written as a filtered colimit \( A = \lim_{\to} \{ A_\alpha \} \), where each \( A_\alpha \in A \). Using the assumption that \( A \) has enough projective objects, we can choose epimorphisms \( P_\alpha \to A_\alpha \), where each \( P_\alpha \) is projective. We then have an epimorphism \( \oplus P_\alpha \to A \). Since \( \oplus P_\alpha \) is projective, we conclude that \( A^\wedge \) has enough projectives.

In what follows, we fix an abelian category \( A \) with enough projective objects, and let \( A \) denote the category of product-preserving functors \( F : A_{\text{proj}}^{\text{op}} \to \text{Set}_\Delta \). We will regard \( A \) as endowed with the simplicial model structure described in Proposition T.5.5.9.1. Note that \( A \) can be identified with the category of simplicial objects of the abelian category \( A^\wedge \). Corollary 1.3.2.12 implies that every object of \( A \) is fibrant. An object \( M_\bullet \) of \( A \) is cofibrant if and only if the chain complex \( N_*(M_\bullet) \) consists of projective objects of \( A^\wedge \).

Using Proposition 1.3.2.22, we obtain an equivalence of \( \infty \)-categories
\[
D^\geq_0(A^\wedge) \simeq N(A^\circ).
\]
Composing with the equivalence of Corollary T.5.5.9.3, we obtain the following result:

**Proposition 1.3.3.14.** Let \( A \) be an abelian category with enough projective objects. Then there exists an equivalence of \( \infty \)-categories
\[
\psi : D^\geq_0(A^\wedge) \to \mathcal{P}(N(A_{\text{proj}}))
\]
whose composition with the inclusion \( N(A_{\text{proj}}) \simeq D^-(A^\wedge)^\circ \subseteq D^\geq_0(A^\wedge) \) is equivalent to the Yoneda embedding \( N(A_{\text{proj}}) \to \mathcal{P}(N(A_{\text{proj}})) \).
Remark 1.3.3.15. We can identify $\mathcal{D}^-(A)$ with a full subcategory of $\mathcal{D}^-(A^\wedge)$. Moreover, an object $P_\bullet \in \mathcal{D}^-(A^\wedge)$ belongs to the essential image of $\mathcal{D}^-(A)$ if and only if the homologies $H_n(P_\bullet)$ belong to $A$, for all $n \in \mathbb{Z}$.

Proposition 1.3.3.16. Let $\mathcal{A}$ be an abelian category with enough projective objects. Then the t-structure on $\mathcal{D}^-(A)$ is right bounded and left complete.

Proof. The right boundedness of $\mathcal{D}^-(A)$ is obvious. To prove the left completeness, we must show that $\mathcal{D}^-(A)$ is a homotopy inverse limit of the tower of $\infty$-categories

$$\ldots \to \mathcal{D}^-(A)_{\leq 1} \to \mathcal{D}^-(A)_{\leq 0} \to \ldots$$

Invoking the right boundedness of $\mathcal{D}^-(A)$, we may reduce to proving that for each $n \in \mathbb{Z}$, $\mathcal{D}^-(A)_{\geq n}$ is a homotopy inverse limit of the tower

$$\ldots \to \mathcal{D}^-(A)_{\leq 1, \geq n} \to \mathcal{D}^-(A)_{\leq 0, \geq n} \to \ldots$$

Shifting if necessary, we may suppose that $n = 0$. Using Remark 1.3.3.15, we can replace $\mathcal{A}$ by $A^\wedge$. For each $k \geq 0$, we let $\mathcal{P}^k_{\Sigma}(N(A_{\text{proj}}))$ denote the $\infty$-category of product-preserving functors from $N(A_{\text{proj}})^{op}$ to $\tau_{\leq k} \Sigma$; equivalently, we can define $\mathcal{P}^k_{\Sigma}(N(A_{\text{proj}}))$ to be the $\infty$-category of $k$-truncated objects of $\mathcal{P}_{\Sigma}(N(A_{\text{proj}}))$. We observe that the equivalence $\psi$ of Proposition 1.3.3.14 restricts to an equivalence

$$\psi(k) : \mathcal{D}^-_{\geq 0}(A^\wedge) \cap \mathcal{D}^-_{\leq k}(A^\wedge) \simeq \mathcal{P}^k_{\Sigma}(N(A_{\text{proj}})).$$

Consequently, it will suffice to show that $\mathcal{P}_{\Sigma}(N(A_{\text{proj}}))$ is a homotopy inverse limit for the tower

$$\ldots \to \mathcal{P}^k_{\Sigma}(N(A_{\text{proj}})) \to \mathcal{P}^{k+1}_{\Sigma}(N(A_{\text{proj}})).$$

Since the truncation functors on $\Sigma$ commute with finite products (Lemma T.6.5.1.2), this follows from the observation that $\Sigma$ is a homotopy inverse limit of the tower

$$\ldots \to \tau_{\leq 1} \Sigma \to \tau_{\leq 0} \Sigma;$$

see Proposition T.7.2.1.10. \qed

Lemma 1.3.3.17. Let $\mathcal{A}$ be a small abelian category with enough projective objects, and let $\mathcal{C} \subseteq \mathcal{P}_{\Sigma}(N(A_{\text{proj}}))$ be the essential image of $\mathcal{D}^-_{\geq 0}(A) \subseteq \mathcal{D}^-_{\geq 0}(A^\wedge)$ under the equivalence $\psi : \mathcal{D}^-_{\geq 0}(A^\wedge) \to \mathcal{P}_{\Sigma}(N(A_{\text{proj}}))$ of Proposition 1.3.3.14. Then $\mathcal{C}$ is the smallest full subcategory of $\mathcal{P}(N(A_{\text{proj}}))$ which is closed under geometric realizations and contains the essential image of the Yoneda embedding.

Proof. It is clear that $\mathcal{C}$ contains the essential image of the Yoneda embedding. Lemma 1.3.3.11 implies that $\mathcal{D}^-_{\geq 0}(A)$ admits geometric realizations and that the inclusion $\mathcal{D}^-_{\geq 0}(A) \subseteq \mathcal{D}^-_{\geq 0}(A^\wedge)$ preserves geometric realizations. It follows that $\mathcal{C}$ is closed under geometric realizations in $\mathcal{P}(N(A_{\text{proj}}))$.

To complete the proof, we will show that every object of $X \in \mathcal{D}^-_{\geq 0}(A)$ can be obtained as the geometric realization, in $\mathcal{D}^-_{\geq 0}(A^\wedge)$, of a simplicial object $P_\bullet$, such that each $P_n \in \mathcal{D}^-_{\geq 0}(A^\wedge)$ consists of a projective object of $\mathcal{A}$, concentrated in degree zero. In fact, we can take $P_\bullet$ to be the simplicial object of $A_{\text{proj}}$ which corresponds to $X \in \text{Ch}_{\geq 0}(A_{\text{proj}})$ under the Dold-Kan correspondence. It follows from Theorem T.4.2.4.1 and Proposition T.5.5.9.14 that $X$ can be identified with the geometric realization of $P_\bullet$. \qed

We are now ready to establish our characterization of $\mathcal{D}^-_{\geq 0}(A)$.

Proof of Theorem 1.3.3.8. Part (1) follows by combining Lemma 1.3.3.17, Remark T.5.3.5.9, and Proposition T.4.3.2.15. The “only if” direction of (2) is obvious. To prove the “if” direction, let us suppose that $F \mid N(A_0)$ preserves finite coproducts. We may assume without loss of generality that $\mathcal{C}$ admits filtered colimits (Lemma T.5.3.5.7), so that $F$ extends to a functor $F' : \mathcal{D}^-_{\geq 0}(A^\wedge) \to \mathcal{C}$ which preserves filtered colimits and geometric realizations (Propositions 1.3.3.14 and T.5.5.8.15). It follows from Proposition T.5.5.8.15 that $F'$ preserves finite coproducts, so that $F = F' \upharpoonright \mathcal{D}^-_{\geq 0}(A)$ also preserves finite coproducts. \qed
1.3.4 Inverting Quasi-Isomorphisms

Let $A$ be an abelian category with enough projective objects, and let $D$ denote its (right-bounded) derived category. The category $D$ admits multiple descriptions:

(a) We can define $D$ explicitly as the category whose objects are chain complexes $P_\ast$ with each $P_n$ a projective object of $A$, and $P_n \simeq 0$ for $n \ll 0$; the morphisms in $D$ are given by chain homotopy equivalence classes of morphisms of chain complexes.

(b) The category $D$ can be obtained by starting with the category $\text{Ch}^{-}(A)$ of all right bounded chain complexes with values in $A$, and formally inverting quasi-isomorphisms.

In §1.3.2, we defined an $\infty$-category $D^{-}(A)$, whose homotopy category $\text{h}D^{-}(A)$ is canonically equivalent to the derived category $D$. Our definition $D^{-}(A)$ can be regarded as an elaboration of (a): objects of $D^{-}(A)$ are right-bounded chain complexes of projective objects of $A$, morphisms are given by chain maps, 2-morphisms by chain homotopies, and so forth (see Definition 1.3.2.7). In this section, we will obtain an alternative description of the $\infty$-category $D^{-}(A)$, which can be regarded as a generalization of (b). To formulate this description, we will need a bit of notation.

**Definition 1.3.4.1.** Let $\mathcal{C}$ be an $\infty$-category and let $W$ be a collection of morphisms in $\mathcal{C}$. We will say that a morphism $f : \mathcal{C} \to D$ exhibits $D$ as the $\infty$-category obtained from $\mathcal{C}$ by inverting the set of morphisms $W$ if, for every $\infty$-category $\mathcal{E}$, composition with $f$ induces a fully faithful embedding $\text{Fun}(D, \mathcal{E}) \to \text{Fun}(\mathcal{C}, \mathcal{E})$, whose essential image is the collection of functors $F : \mathcal{C} \to \mathcal{E}$ which carry each morphism in $W$ to an equivalence in $\mathcal{E}$. In this case, the $\infty$-category $D$ is determined uniquely up to equivalence by $\mathcal{C}$ and $W$, and will be denoted by $\mathcal{C}[W^{-1}]$.

If $\mathcal{C}$ is an ordinary category and $W$ is a collection of morphisms in $\mathcal{C}$, we let $\mathcal{C}[W^{-1}]$ denote the $\infty$-category $N(\mathcal{C})[W^{-1}]$.

**Remark 1.3.4.2.** For any $\infty$-category $\mathcal{C}$ and any collection $W$ of morphisms of $\mathcal{C}$, the $\infty$-category $\mathcal{C}[W^{-1}]$ is defined: that is, there exists a functor $f : \mathcal{C} \to D$ which exhibits $D$ as the $\infty$-category obtained from $\mathcal{C}$ by inverting $W$. To prove this, we can assume without loss of generality that $W$ contains all degenerate edges of $\mathcal{C}$, in which case $\mathcal{C}[W^{-1}]$ can be identified with a fibrant replacement for the pair $(\mathcal{C}, W)$ in the category $\text{Set}_\Delta^+ \text{ of marked simplicial sets}$ (see §T.3.1).

**Example 1.3.4.3.** Let $\mathcal{C}$ be an $\infty$-category, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a localization of $\mathcal{C}$: that is, $\mathcal{C}_0$ is a full subcategory of $\mathcal{C}$, and the inclusion $\mathcal{C}_0 \hookrightarrow \mathcal{C}$ admits a left adjoint $L$. Let $W$ be the collection of those morphisms $\alpha$ in $\mathcal{C}$ such that $L(\alpha)$ is an equivalence. Then the composite functor $\mathcal{C}_0 \to \mathcal{C} \to \mathcal{C}[W^{-1}]$ is an equivalence of $\infty$-categories, so that we can identify $\mathcal{C}_0$ with the $\infty$-category $\mathcal{C}[W^{-1}]$ (see Proposition T.5.2.7.12).

We now can formulate our main result as follows:

**Theorem 1.3.4.4.** Let $A$ be an abelian category with enough projective objects, let $A = \text{Ch}^{-}(A)$ (regarded as an ordinary category), and let $W$ be the collection of morphisms in $A$ which are quasi-isomorphisms of chain complexes (that is, the collection of all morphisms which induce isomorphisms on homology). Then there is a canonical equivalence of $\infty$-categories $A[W^{-1}] \simeq D^{-}(A)$.

The main ingredient in the proof of Theorem 1.3.4.4 is the following result, which we will prove later in this section:

**Proposition 1.3.4.5.** Let $A$ be an additive category, let $\text{Ch}'(A)$ be a full subcategory of $\text{Ch}(A)$, let $A$ denote the underlying discrete category of $\text{Ch}'(A)$, and let $W$ be the collection of chain homotopy equivalences in $A$. Assume that for every object $M_\ast \in \text{Ch}'(A)$, the tensor product $N_\ast(\Delta^1) \otimes M_\ast$ (that is, the mapping cylinder of the identity map $\text{id} : M_\ast \to M_\ast$) also belongs to $\text{Ch}'(A)$. Then the inclusion $\theta : N(A) \hookrightarrow N_{dg}(\text{Ch}'(A))$ of Remark 1.3.1.9 induces an equivalence of $\infty$-categories $\theta' : A[W^{-1}] \simeq N_{dg}(\text{Ch}'(A))$ (see Notation 4.1.3.3).
We will also need the following observation:

**Proposition 1.3.4.6.** Let \( A \) be an abelian category with enough projective objects. Then:

1. The inclusion of \( \infty \)-categories \( \mathcal{D}^-(A) \hookrightarrow N_{\text{dg}}(\text{Ch}^-(A)) \) admits a right adjoint \( G \).
2. Let \( \alpha \) be a morphism in \( N_{\text{dg}}(\text{Ch}^-(A)) \). Then \( G(\alpha) \) is an equivalence in \( \mathcal{D}^-(A) \) if and only if \( \alpha \) is a quasi-isomorphism of chain complexes.
3. Let \( W \) be the collection of all morphisms in \( N_{\text{dg}}(\text{Ch}^-(A)) \) which are quasi-isomorphisms of chain complexes. Then we have a canonical equivalence of \( \infty \)-categories

\[
N_{\text{dg}}(\text{Ch}^-(A))[W^{-1}] \simeq \mathcal{D}^-(A).
\]

**Proof.** We first note that if \( f : M_* \to N_* \) is a quasi-isomorphism of chain complexes with values in \( A \), then Lemma 1.3.2.20 implies that \( f \) induces a quasi-isomorphism

\[
\text{Map}_{\text{Ch}(A)}(P_*, M_*) \to \text{Map}_{\text{Ch}(A)}(P_*, N_*)
\]

for of chain complexes of abelian groups, for every object \( P_* \in \mathcal{D}^-(A) \). Assertion (*) in the proof of Proposition 1.3.2.19 shows that for every object \( N_* \in \text{Ch}^-(A) \), we can choose a quasi-isomorphism \( f : M_* \to N_* \), where \( M_* \in \mathcal{D}^-(A) \). Assertion (1) now follows from Proposition T.5.2.7.8. Moreover, we immediately deduce the “if” direction of (2). For the converse, suppose that \( f : M_* \to N_* \) is a morphism in \( N_{\text{dg}}(\text{Ch}^-(A)) \) and that \( G(f) \) is an equivalence; we wish to prove that \( f \) is a quasi-isomorphism. We have a commutative diagram

\[
\begin{array}{ccc}
G(M_*) & \xrightarrow{G(f)} & G(N_*) \\
\downarrow & & \downarrow \\
M_* & \xrightarrow{f} & N_*
\end{array}
\]

in the \( \infty \)-category \( N_{\text{dg}}(\text{Ch}^-(A)) \). The vertical maps are quasi-isomorphisms by construction, and the upper horizontal map is a chain homotopy equivalence. It follows that \( f \) is also a quasi-isomorphism. This completes the proof of (2); assertion (3) now follows from Example 1.3.4.3.

**Proof of Theorem 1.3.4.4.** Let \( A \) denote the ordinary category underlying \( \text{Ch}^-(A) \), let \( W \) be the collection of quasi-isomorphisms in \( A \), and let \( W_0 \subseteq W \) be the collection of chain homotopy equivalences in \( A \). Propositions 1.3.4.5 and 1.3.4.6 supply equivalences of \( \infty \)-categories

\[
N_{\text{dg}}(\text{Ch}^-(A)) \simeq A[W_0^{-1}] \quad \mathcal{D}^-(A) \simeq N_{\text{dg}}(\text{Ch}^-(A))[W^{-1}],
\]

from which we immediately obtain an equivalence of \( \infty \)-categories \( \mathcal{D}^-(A) \simeq A[W^{-1}] \).

We now turn to the proof of Proposition 1.3.4.5. We have already seen that the differential graded nerve \( N_{\text{dg}}(\text{Ch}'(A)) \) is equivalent to the nerve of the simplicial category underlying \( \text{Ch}'(A) \) (Proposition 1.3.1.17). We therefore ask the following general question: given a simplicial category \( \mathcal{C} \), under what circumstances can we recover the homotopy coherent nerve \( N(\mathcal{C}) \) from the underlying ordinary category of \( \mathcal{C} \), by inverting the class of homotopy equivalences? The following result provides a useful criterion:

**Proposition 1.3.4.7.** Let \( \mathcal{C} \) be a simplicial category and let \( W \) be a collection of morphisms in \( \mathcal{C} \). Assume that the following conditions are satisfied:

1. Every isomorphism in \( \mathcal{C} \) belongs to \( W \).
1.3. HOMOLOGICAL ALGEBRA AND DERIVED CATEGORIES

(2) Given a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{h} & Z \\
\downarrow{f} & & \downarrow{g} \\
Y & \xrightarrow{h} & Z
\end{array}
\]

in \( \mathcal{C} \), if any two of the morphisms \( f, g, \) and \( h \) belong to \( W \), then so does the third.

(3) For every object \( X \in \mathcal{C} \), there exists an interval object \( \Delta^1 \otimes X \) equipped with a map \( h : \Delta^1 \to \text{Map}_\mathcal{C}(X, \Delta^1 \otimes X) \) having the following universal property: for every object \( Y \in \mathcal{C} \), composition with \( h \) determines an isomorphism of simplicial sets

\[
\text{Map}_\mathcal{C}(\Delta^1 \otimes X, Y) \to \text{Map}_{\text{Set}_\Delta}(\Delta^1, \text{Map}_\mathcal{C}(X, Y)).
\]

(4) For each \( X \in \mathcal{C} \), the canonical map \( \Delta^1 \otimes X \to X \) belongs to \( W \).

Let \( \mathcal{C}_0 \) denote the underlying ordinary category of \( \mathcal{C} \) and let \( \mathcal{C}' \) be a fibrant replacement for \( \mathcal{C} \) (in the category \( \mathcal{C}_{\text{at}}_\Delta \) of simplicial categories). Then the canonical map \( \theta : (N(\mathcal{C}_0), W) \to (N(\mathcal{C}'), W) \) is a weak equivalence of marked simplicial sets.

Example 1.3.4.8. If \( \mathcal{C} \) is a fibrant simplicial category, then we can take \( \mathcal{C}' = \mathcal{C} \). Assume that \( \mathcal{C} \) admits interval objects (that is, \( \mathcal{C} \) satisfies condition (3) of Proposition 1.3.4.7), and let \( W \) be the collection of homotopy equivalences in \( \mathcal{C} \). Then Proposition 1.3.4.7 provides an equivalence of \( \infty \)-categories \( \mathcal{C}_0[\mathcal{W}^{-1}] \simeq N(\mathcal{C}) \).

Warning 1.3.4.9. As stated, Proposition 1.3.4.7 does quite apply to the underlying simplicial category of the differential graded category \( \text{Ch} '(A) \) appearing in Proposition 1.3.4.5. The problem is with hypothesis (3): the construction \( (K, M_\cdot) \mapsto N_\cdot(K) \otimes M_\cdot \) does not exhibit \( \text{Ch}(A) \) as tensored over the category of simplicial sets (see Warning 1.3.5.4). However, we obtain a proof of Proposition 1.3.4.5 by slightly modifying the proof of Proposition 1.3.4.7 given below.

The proof of Proposition 1.3.4.7 will require some preliminaries.

Lemma 1.3.4.10. Let \( J \) be a category and suppose we are given a diagram \( u : J \to \mathcal{C}_{\text{at}}_\Delta \), which we will denote by \( \alpha \mapsto \mathcal{C}_\alpha \), together with a map of simplicial categories \( \theta : \lim_{\Delta} \mathcal{C}_\alpha \to \mathcal{C} \). Suppose furthermore that the following conditions are satisfied:

(1) For every index \( \alpha \), the simplicial functor \( f_\alpha : \mathcal{C}_\alpha \to \mathcal{C} \) is bijective on objects.

(2) For every pair of objects \( x, y \in \mathcal{C} \), the canonical map

\[
\lim_{\alpha} \text{Map}_{\mathcal{C}_\alpha}(f^{-1}_\alpha x, f^{-1}_\alpha y) \to \text{Map}_{\mathcal{C}}(x, y)
\]

exhibits \( \text{Map}_{\mathcal{C}}(x, y) \) as a homotopy colimit of the diagram of simplicial sets \( \{ \text{Map}_{\mathcal{C}_\alpha}(f^{-1}_\alpha x, f^{-1}_\alpha y) \}_{\alpha \in J} \).

(3) The \( \infty \)-category \( N(J) \) is sifted.

Then \( \theta \) exhibits \( \mathcal{C} \) as a homotopy colimit of the diagram \( \{ \mathcal{C}_\alpha \} \).

Proof. Let \( S \) be the set of objects of \( \mathcal{C} \). Let \( A = \text{Set}_\Delta^{S \times S} \) be the category whose objects are collections of simplicial sets \( \{ X_{s,t} \}_{s,t \in S} \). The standard model structure on \( \text{Set}_\Delta \) determines a model structure on the category \( A \), where fibrations, cofibrations, and weak equivalences are given pointwise. Note that \( A \) has the structure of a monoidal model category, where the tensor product is given by the formula

\[
(X \otimes Y)_{s,t} = \prod_{u \in S} X_{s,u} \times Y_{u,t}.
\]
Since every object of $\mathbf{A}$ is cofibrant, Proposition 4.1.4.3 implies that $\mathbf{Alg}(\mathbf{A})$ inherits the structure of a combinatorial model category. The objects of $\mathbf{Alg}(\mathbf{A})$ can be identified simplicial categories whose underlying set of objects is $S$. Consequently, we have a forgetful functor $F : \mathbf{Alg}(\mathbf{A}) \to (\mathbf{Cat}_\Delta)_{\mathbf{S}^\circ}$ (where we regard $\mathbf{S}^\circ$ as a simplicial category via the formula $\text{Map}(\mathbf{C}, X) = \Delta^0$ if $s = t$, $\emptyset$ if $s \neq t$). Note that $\mathbf{C} \simeq F(A)$ for some $A \in \mathbf{Alg}(\mathbf{A})$.

Condition (1) implies that $u$ is isomorphic to a functor given by the composition $\mathbf{J} \xrightarrow{u'} \mathbf{Alg}(\mathbf{A}) \xrightarrow{F} \mathbf{Cat}_\Delta$, and that $\theta$ is obtained from a map $\theta' : \lim_{\mathbf{S}}(u') \to A$ in $\mathbf{Alg}(\mathbf{A})$. Since $F$ is a left Quillen functor which preserves weak equivalences, it preserves homotopy colimits; consequently, it will suffice to show that $\theta'$ exhibits $A$ as a homotopy colimit of $u'$ in the model category $\mathbf{Alg}(\mathbf{A})$. Using condition (3) and Lemma 4.1.4.13, we are reduced to proving that $\theta'$ exhibits $A$ as a homotopy colimit of $u'$ in the model category $\mathbf{A}$, which is equivalent to condition (2).

**Notation 1.3.4.11.** Let $\mathbf{C}$ be a simplicial category. We can regard $\mathbf{C}$ as a simplicial object in the category $\mathbf{Cat}$: that is, for each $[n] \in \Delta$, let $\mathbf{C}_n$ denote the category whose objects are the objects of $\mathbf{C}$, with $\text{Hom}_{\mathbf{C}_n}(x, y) = \text{Hom}_{\mathbf{Set}_\Delta}(\Delta^n, \text{Map}_\mathbf{C}(x, y))$.

For $[n] \in \Delta$, let $t_{[n]} : \mathbf{Set}_\Delta \to \mathbf{Set}_\Delta$ be the translation functor described by the formula $\text{Hom}_{\mathbf{Set}_\Delta}(X, t_{[n]}Y) \simeq \text{Hom}_{\mathbf{Set}_\Delta}(\Delta^n \times X, Y)$. Then $t_{[n]}$ preserves products and therefore induces a functor $T_{[n]} : \mathbf{Cat}_\Delta \to \mathbf{Cat}_\Delta$. For any simplicial category $\mathbf{C}$, there is an evident pair of maps $\mathbf{C}_n \leftarrow t_{[n]} \mathbf{C} \to \mathbf{C}$.

Allowing $[n]$ to vary, we obtain a simplicial object $T_{\bullet}\mathbf{C}$ of $\mathbf{Cat}_\Delta$, equipped with a map of simplicial objects $T_{\bullet}\mathbf{C} \to \mathbf{C}$, and a map of simplicial categories $\text{lim}_n T_{\bullet}\mathbf{C} \to \mathbf{C}$.

**Lemma 1.3.4.12.** Let $X$ be a simplicial set. Then for each $m \geq 0$, the canonical map $t_{[m]}X \to \text{Hom}_{\mathbf{Set}_\Delta}(\Delta^m, X)$ is a homotopy equivalence.

**Proof.** Unwinding the definitions, we have an isomorphism $t_{[m]}X \simeq \coprod_{\sigma : \Delta^m \to X} X_{\sigma^\circ}$, where each summand is weakly contractible.

**Lemma 1.3.4.13.** Let $X$ be a simplicial set. Then the canonical map $\text{lim}_n t_{[n]}(X) \to X$ exhibits $X$ as a homotopy colimit of the diagram $[n] \mapsto t_{[n]}(X)$.

**Proof.** Since the collection of homotopy colimit diagrams is stable under filtered colimits, we may assume without loss of generality that $X$ is finite. We work by induction on the dimension $n$ of $X$ and the number of nondegenerate $n$-simplices of $X$. If $X$ is empty, the result is obvious; otherwise, we have a homotopy pushout diagram

$$
\begin{array}{ccc}
\partial \Delta^n & \rightarrow & \Delta^n \\
\downarrow & & \downarrow \\
X' & \rightarrow & X.
\end{array}
$$

Using the inductive hypothesis, we deduce that $X'$ and $\partial \Delta^n$ can be identified with the homotopy colimit of the diagrams $t_\bullet X'$ and $t_\bullet (\partial \Delta^n)$. Consequently, to prove that $X$ is the homotopy colimit of $t_\bullet X$, it suffices to show that $\Delta^n$ is a homotopy colimit of $t_\bullet \Delta^n$: in other words, we wish to show that the homotopy colimit of $t_\bullet \Delta^n$ is contractible. Using Lemma 1.3.4.12, we are reduced to showing that the diagram $[m] \mapsto \text{Hom}_{\mathbf{Set}_\Delta}(\Delta^m, \Delta^n)$ has a contractible homotopy colimit, which follows from Corollary T.A.2.9.30.

Proposition 1.3.4.14. Let $\mathcal{C}$ be a simplicial category. Then $\mathcal{C}$ can be identified with the geometric realization of the simplicial object $\mathcal{C}_n$ in $\text{Cat} \subseteq \text{Cat}_\Delta$. More precisely, the map $T_n \mathcal{C} \to \mathcal{C}_n$ is a weak equivalence of simplicial objects of $\text{Cat}_\Delta$, and the map $\lim \rightarrow T_n \mathcal{C} \to \mathcal{C}$ exhibits $\mathcal{C}$ as a homotopy colimit of the simplicial object $T_n \mathcal{C}$.

Proof. We first claim that for $n \geq 0$, the canonical map $T_n \mathcal{C} \to \mathcal{C}_n$ is a weak equivalence of simplicial categories. Since this map is bijective on objects, it suffices to show that for every pair of objects $x, y \in \mathcal{C}$, the map $\text{Map}_{T_n \mathcal{C}}(x, y) \to \text{Hom}_{\mathcal{C}_n}(x, y)$ is a weak homotopy equivalence, which follows from Lemma 1.3.4.12.

We next show that $\mathcal{C}$ can be identified with the homotopy colimit of the diagram $T_n \mathcal{C}$. Using Lemma 1.3.4.10, we are reduced to proving that for every pair of objects $x, y \in \mathcal{C}$, the map $\text{Map}_n(x, y)$ is a homotopy colimit of the diagram $[n] \to t[n]\text{Map}_n(x, y)$; this follows from Lemma 1.3.4.13. \qed

Proof of Proposition 1.3.4.7. We let $|\mathcal{C}|$ denote the topological category obtained from the simplicial category $\mathcal{C}$ by geometric realization (that is, $|\mathcal{C}|$ has the same objects as $\mathcal{C}$, with morphism spaces given by $\text{Map}_0(\mathcal{C})(X, Y) = |\text{Map}_n(\mathcal{C})(X, Y)|$). We may assume without loss of generality that $\mathcal{C}'$ is the underlying simplicial category of $|\mathcal{C}|$, so that the homotopy coherent nerve $N(\mathcal{C}')$ is isomorphic to the nerve of the topological category $|\mathcal{C}|$.

Fix an object $X \in \mathcal{C}$, and let $h : \Delta^1 \to \text{Map}_0(\mathcal{C})(X, \Delta^1 \otimes X)$ be as in (3). Restricting to vertices, we obtain a pair of morphisms $h_0, h_1 : X \to \Delta^1 \otimes X$. These maps are both right inverse to the projection $\Delta^1 \otimes X \to X$. Using (1), (2), and (4), we deduce that $h_0$ and $h_1$ belong to $W$. Suppose that $f : X \to Y$ is a morphism in $\mathcal{C}$ which belongs to $W$, and that $f' : X \to Y$ is another morphism which is connected to $f$ by an edge of $\text{Map}_0(\mathcal{C})(X, Y)$. This edge determines a map $F : \Delta^1 \otimes X \to Y$ such that $f = F \circ h_0$ and $f' = F \circ h_1$. Using (2) we deduce that $F \in W$ and therefore $f' \in W$. It follows that if $g : X \to Y$ is any morphism which belongs to the same connected component of $\text{Map}_0(\mathcal{C})(X, Y)$ as $f$, then $g \in W$.

For each $n \geq 0$ let $W_n$ be the collection of morphisms in $\mathcal{C}_n$ which correspond to maps $\Delta^n \to \text{Map}_0(\mathcal{C})(X, Y)$ which carry each vertex to an element of $W$, and let $W'_n$ be the collection of morphisms in the simplicial category $T_n \mathcal{C}$ whose image in $\mathcal{C}_n$ belongs to $W_n$. The map $\theta$ factors as a composition

$$(N(\mathcal{C}_0), W) \xrightarrow{\theta'} \text{hocolim}(N(|T_n \mathcal{C}|), W'_n) \xrightarrow{\theta''} (N(|\mathcal{C}|), W).$$

It will therefore suffice to prove that $\theta'$ and $\theta''$ are weak equivalences. For the map $\theta''$, this is an immediate consequence of Proposition 1.3.4.14.

We now show that $\theta'$ is a weak equivalence. Consider the composite map

$$(N(\mathcal{C}_0), W) \xrightarrow{\theta'} \text{hocolim}(N(|T_n \mathcal{C}|), W'_n) \xrightarrow{\phi} \text{hocolim}(N(\mathcal{C}_n), W_n).$$

Each of the maps $T_n \mathcal{C} \to \mathcal{C}_n$ is a weak equivalence of simplicial categories, so that $\phi$ is a weak equivalence of marked simplicial sets. It therefore suffices to show that the composite map $\phi \circ \theta'$ is a weak equivalence. Since $N(\Delta)^op$ is weakly contractible, it will suffice to show that $[n] \to (N(\mathcal{C}_n), W_n)$ determines a constant diagram in the homotopy category $\text{hSet}_\Delta^+$. Equivalently, we must show that for each $n \geq 0$, the map $[n] \to [0]$ induces a weak equivalence of marked simplicial sets $F: (N(\mathcal{C}_n), W_n) \to (N(\mathcal{C}_n), W_n)$. Let $G : (N(\mathcal{C}_n), W_n) \to (N(\mathcal{C}_n), W_n)$ be the map induced by the inclusion $[0] \to [n]$. Then $G \circ F = \text{id}$. To complete the proof, it will suffice to show that $F \circ G$ is homotopic to the identity map. To this end, we define a functor $U : \mathcal{C}_n \to \mathcal{C}_n$ as follows:

- On objects, $U$ is given by $U(X) = \Delta^1 \otimes X$.
- Let $\alpha : X \to Y$ be a morphism in $\mathcal{C}_n$ corresponding to a map $\Delta^n \to \text{Map}_0(\mathcal{C})(X, Y)$. Then $U(\alpha)$ corresponds to the map $\Delta^n \to \text{Map}_0(\mathcal{C})(\Delta^1 \otimes X, \Delta^1 \otimes Y)$ given by

$$\Delta^n \times \Delta^1 \xrightarrow{\epsilon} \Delta^n \times \Delta^1 \xrightarrow{\alpha} \text{Map}_0(\mathcal{C})(X, Y) \times \Delta^1 \to \text{Map}_0(\mathcal{C})(X, \Delta^1 \otimes Y),$$
where \( r \) is given on vertices by the formula
\[
    r(i, j) = \begin{cases} 
    (0, 0) & \text{if } j = 0 \\
    (i, 1) & \text{if } j = 1.
    \end{cases}
\]

The inclusions \( \{0\} \hookrightarrow \Delta^1 \hookrightarrow \{1\} \) determine natural transformations \( F \circ G \to U \leftarrow \text{id} \). Conditions (1), (2), and (4) guarantee that these transformations are given by morphisms in \( W_n \), and therefore determine a homotopy from \( F \circ G \) to the identity. \( \square \)

We now prove Proposition 1.3.4.5 using a similar strategy.

**Proof of Proposition 1.3.4.5.** For each \([n] \in \Delta\), let \( \mathcal{C}_n \) denote the category whose objects are the objects of \( \text{Ch}'(A) \), with morphisms given by
\[
    \Hom_{\mathcal{C}_n}(M_s, M'_s) \simeq \Hom_{\text{Ch}(A)}(\Delta^n, M_s, M'_s).
\]

Then \( \mathcal{C}_* \) is a simplicial object of \( \mathcal{C} \) arising from a simplicial category \( \mathcal{C} \), and Proposition 1.3.1.17 supplies an equivalence of \( \infty \)-categories \( \mathcal{N}(\mathcal{C}) \to \mathcal{N}_{\text{dg}}(\text{Ch}'(A)) \). It will therefore suffice to show that the inclusion \( \mathcal{N}(\mathcal{C}_0) \hookrightarrow \mathcal{N}(\mathcal{C}) \) induces an equivalence \( \mathcal{N}(\mathcal{C}_0) [W^{-1}] \to \mathcal{N}(\mathcal{C}) \). For each \( n \geq 0 \), let \( W_n \) be the collection of morphisms in the category \( \mathcal{C}_n \) defined as in the proof of Proposition 1.3.4.7.

Let \( T_* \mathcal{C} \) be the simplicial object of \( \mathcal{C} \text{-Cat}_A \) introduced in Notation 1.3.4.11, and let \( \overline{W}_n \) be the collection of morphisms in \( T_n \mathcal{C} \) whose images in \( \mathcal{C}_n \) belong to \( W_n \). Proposition 1.3.4.14 yields weak equivalences of simplicial categories
\[
    \text{hocolim} \mathcal{C}_* \leftarrow \text{hocolim} T_* \text{Ch}'(A) \to \text{Ch}'(A).
\]

Moreover, the map on the right carries each morphism in \( \overline{W}_n \) to a homotopy equivalence in \( \text{Ch}'(A) \), so we obtain categorical equivalences
\[
    \text{hocolim} \mathcal{N}(\mathcal{C}_*) [W^{-1}] \leftarrow \text{hocolim} \mathcal{N}(T_* \text{Ch}'(A)) [\overline{W}^{-1}] \to \mathcal{N}(\text{Ch}'(A)).
\]

The map \( \theta \) factors naturally through \( \mathcal{N}(T_0 \text{Ch}'(A)) \) so that the composite map \( \mathcal{N}(A) \to \mathcal{N}(T_0 \text{Ch}'(A)) \to \mathcal{N}(\mathcal{C}_0) \) is an isomorphism. Consequently, to prove that \( \theta \) is an equivalence of \( \infty \)-categories, it will suffice to show that the natural map \( \mathcal{N}(\mathcal{C}_0) [W^{-1}] \to \text{hocolim} \mathcal{N}(\mathcal{C}_*) [W^{-1}] \) is a categorical equivalence. We will prove this by showing that the diagram \( \mathcal{N}(\mathcal{C}_*) [W^{-1}] \) is essentially constant: that is, for each \( n \geq 0 \), the map \( [n] \to [0] \) in \( \Delta \) induces a weak equivalence of marked simplicial sets
\[
    F : (\mathcal{N}(\mathcal{C}_0), W_0^{-1}) \to (\mathcal{N}(\mathcal{C}_n), W_n^{-1}).
\]

Let \( G : (\mathcal{N}(\mathcal{C}_n), W_n) \to (\mathcal{N}(\mathcal{C}_0), W_0) \) be the map induced by the inclusion \( [0] \hookrightarrow [n] \). Then \( G \circ F = \text{id} \). To complete the proof, it will suffice to show that \( F \circ G \) is homotopic to the identity map in the model category \( \text{Set}^+_\Delta \). We will prove this by an explicit construction.

Given a sequence \( i_0 < i_1 < \cdots < i_k \) corresponding to a nondegenerate \( k \)-simplex of \( \Delta^n \), we let \([i_0, \ldots, i_k]\) denote the corresponding generator for the free abelian group \( N_*(\Delta^k) \). We define a map of chain complexes \( \chi : N_*(\Delta^n) \otimes N_*(\Delta^1) \to N_*(\Delta^1) \otimes N_*(\Delta^n) \) by the formula
\[
    \chi([i_0, \ldots, i_k] \otimes [0]) = \begin{cases} 
    [0] \otimes [0] & \text{if } k = 0 \\
    0 & \text{otherwise}.
    \end{cases}
\]

\[
    \chi([i_0, \ldots, i_k] \otimes [1]) = [1] \otimes [i_0, \ldots, i_k]
\]

\[
    \chi([i_0, \ldots, i_k] \otimes [0, 1]) = \begin{cases} 
    (-1)^k [0, 1] \otimes [i_0, \ldots, i_k] & \text{if } i_0 = 0 \\
    (-1)^k [0, 1] \otimes [i_0, \ldots, i_k] + (-1)^k [0] \otimes [0, i_0, \ldots, i_k] & \text{if } i_0 > 0.
    \end{cases}
\]
For objects $M, M' \in \text{Ch}'(A)$, every morphism $\phi \in \text{Hom}_e_n(M, M')$ determines a map

$$\phi' : N_e(\Delta^n) \otimes N_e(\Delta^1) \otimes M \to N_e(\Delta^1) \otimes N_e(\Delta^n) \otimes M \to N_e(\Delta^1) \otimes M'.$$

The construction $\phi \mapsto \phi'$ determines a functor $U$ from $\mathcal{C}_n$ to itself, given on objects by $M \mapsto N_e(\Delta^1) \otimes M$. Moreover, the inclusions $\{0\} \hookrightarrow \Delta^1 \hookrightarrow \{1\}$ determine natural transformations

$$F \circ G \to U \leftarrow \text{id}.$$

Since the underlying maps $M \to N_e(\Delta^1) \otimes M$ are chain homotopy equivalences, these natural transformations show that $\text{id}$ and $F \circ G$ are both homotopic to $U$, and are therefore homotopic to each other. 

We conclude this section by describing some other applications of Proposition 1.3.4.7. Recall that we can associate an $\infty$-category to each simplicial model category $A$, via the construction $A \mapsto N(A^\circ)$ (here $A^\circ$ denotes the full subcategory of $A$ spanned by the fibrant-cofibrant objects). However, many model categories which naturally arise which are not simplicial (we will study some examples in §1.3.5). In these cases, we cannot produce an $\infty$-category directly using the homotopy coherent nerve. However, we can still associate an underlying $\infty$-category via the following procedure:

**Definition 1.3.4.15.** Let $A$ be a model category. We let $A^c$ denote the full subcategory of $A$ spanned by the cofibrant objects. Let $\mathcal{C}$ be an $\infty$-category. We will say that a functor $f : N(A^c) \to \mathcal{C}$ exhibits $\mathcal{C}$ as the underlying $\infty$-category of $A$ if $f$ induces an equivalence $N(A^c)[W^{-1}] \simeq \mathcal{C}$, where $W$ is the collection of weak equivalences in $A^c$.

**Remark 1.3.4.16.** In Definition 1.3.4.15, we restrict our attention to cofibrant objects of $A$ in order to facilitate applications to the study of monoidal model categories: if $A$ is a monoidal model category, then the tensor product on $A^c$ preserves weak equivalences. Other variations on Definition 1.3.4.15 are possible. For example, we could define the underlying $\infty$-category of $A$ to be the $\infty$-category obtained from $A$, from the fibrant objects of $A$, or from the fibrant-cofibrant objects of $A$, by formally inverting all weak equivalences. If we assume that the morphisms $f : X \to Y$ in $A$ admit factorizations

$$X \xrightarrow{\alpha} U(f) \xrightarrow{\beta} Y \quad X \xrightarrow{\alpha'} V(f) \xrightarrow{\beta'} Y$$

(where $\alpha$ is a cofibration, $\alpha'$ a trivial cofibration, $\beta$ a trivial fibration, and $\beta'$ a fibration) which can be chosen functorially in $f$, then all of these approaches are equivalent to Definition 1.3.4.15. The functorial factorization condition is always satisfied in practice (and is sometimes taken as part of the definition of a model category); it is automatic, for example, if $A$ is a combinatorial model category.

Our goal now is to show that if $A$ is a simplicial model category, then the underlying $\infty$-category of $A$ is given by the homotopy coherent nerve $N(A^\circ)$ (Theorem 1.3.4.20). We begin by constructing a functor from the ordinary category $A^c$ to the $\infty$-category $N(A^\circ)$.

**Notation 1.3.4.17.** In what follows, we will always regard $A^c$ as a discrete category, even in cases where $A$ is equipped with the structure of a simplicial model category.

**Construction 1.3.4.18.** Let $A$ be a simplicial model category. We define a simplicial category $M$ as follows:

1. An object of $M$ is a pair $(i, A)$, where $i \in \{0, 1\}$ and $A$ is a cofibrant object of $A$, which is fibrant when $i = 1$.

2. Given a pair of objects $(i, A)$ and $(j, B)$ in $M$, we have

$$\text{Map}_M((i, A), (j, B)) = \begin{cases} \text{Map}_A(A, B) & \text{if } j = 1 \\ \text{Hom}_A(A, B) & \text{if } i = j = 0 \\ 0 & \text{if } j = 0 < 1 = i. \end{cases}$$
We note that the mapping spaces in \( \mathcal{M} \) are fibrant, so that \( N(\mathcal{M}) \) is an \( \infty \)-category. There is an evident forgetful functor \( p : N(\mathcal{M}) \to \Delta^1 \), which exhibits \( N(\mathcal{M}) \) as a correspondence from \( N(\mathcal{M})_0 \simeq N(\mathcal{A}^c) \) to \( N(\mathcal{M})_1 \simeq N(\mathcal{A}^o) \).

**Lemma 1.3.4.19.** Let \( \mathcal{A} \) be a simplicial model category, and let \( \mathcal{M} \) be defined as in Construction 1.3.4.18. Then the projection map \( p : N(\mathcal{M}) \to \Delta^1 \) is a coCartesian fibration. Moreover, if \( f : (i, A) \to (j, B) \) is a morphism in \( N(\mathcal{M}) \) with \( i = 0 < 1 = j \), then \( p \) is \( p \)-coCartesian if and only if the induced map \( A \to B \) is a weak equivalence in \( \mathcal{A} \).

**Proof.** Choose an object \((0, A) \in N(\mathcal{M})_0 \), and choose a trivial cofibration \( A \to B \) where \( B \) is a fibrant object of \( \mathcal{A} \). We will show that the induced map \((0, A) \to (1, B) \) in \( N(\mathcal{M}) \) is \( p \)-coCartesian. This will prove that \( p \) is a coCartesian fibration and the “if” direction of the final assertion; the “only if” will then follow from the uniqueness of coCartesian morphisms up to equivalence. Using Proposition T.2.4.4.3, we are reduced to proving the following assertion: for every object \( C \in \mathcal{A}^o \), composition with \( f \) induces a homotopy equivalence \( \text{Map}_{\mathcal{A}}(B, C) \to \text{Map}_{\mathcal{A}}(A, C) \). This follows from the fact that \( C \) is fibrant and \( f \) is a weak equivalence between cofibrant objects. \( \square \)

It follows from Lemma 1.3.4.19 that the correspondence \( N(\mathcal{M}) \to \Delta^1 \) determines a functor \( \theta : N(\mathcal{A}^c) \to N(\mathcal{A}^o) \), which is well-defined up to equivalence. We now have the following result:

**Theorem 1.3.4.20.** [Dwyer-Kan] Let \( \mathcal{A} \) be a simplicial model category, let \( \theta : N(\mathcal{A}^c) \to N(\mathcal{A}^o) \) be the functor constructed above, and let \( \mathcal{W} \) be the collection of weak equivalences in \( \mathcal{A}^c \). Then \( \theta \) induces an equivalence \( \mathcal{A}^c[W^{-1}] \to N(\mathcal{A}^o) \) (that is, \( \theta \) exhibits \( N(\mathcal{A}^o) \) as the underlying \( \infty \)-category of \( \mathcal{A} \), in the sense of Definition 1.3.4.15).

Before giving the proof of Theorem 1.3.4.20, let us collect a few consequences concerning the structure of the underlying \( \infty \)-category of an arbitrary combinatorial model category.

**Lemma 1.3.4.21.** Let \( F : \mathcal{A} \to \mathcal{B} \) be a left Quillen equivalence between combinatorial model categories. Let \( \mathcal{A}^c \) and \( \mathcal{B}^c \) denote the full subcategories of \( \mathcal{A} \) and \( \mathcal{B} \) spanned by the cofibrant objects, and let \( \mathcal{W}_A \) and \( \mathcal{W}_B \) be the collection of weak equivalences in \( \mathcal{A}^c \) and \( \mathcal{B}^c \), respectively. Then \( F \) induces a weak equivalence of marked simplicial sets

\[
f : (N(\mathcal{A}^c), \mathcal{W}_A) \to (N(\mathcal{B}^c), \mathcal{W}_B).
\]

In other words, a left Quillen equivalence between combinatorial model categories induces an equivalence between their underlying \( \infty \)-categories.

**Proof.** Since \( \mathcal{A} \) is combinatorial, there exists a cofibrant replacement functor \( P : \mathcal{A} \to \mathcal{A} \). That is, \( P \) is a functor equipped with a natural transformation \( u : P \to \text{id} \) such that, for every object \( X \in \mathcal{A} \), the induced map \( u_X : P(X) \to X \) is a weak equivalence and \( P(X) \) is cofibrant. Similarly, we can choose a fibrant replacement functor \( Q : \mathcal{B} \to \mathcal{B} \). Let \( G \) be a right adjoint to \( F \), and let \( G' : \mathcal{B}^c \to \mathcal{A}^c \) be the functor given by the composition

\[
\mathcal{B}^c \xrightarrow{Q} \mathcal{B} \xrightarrow{G} \mathcal{A} \xrightarrow{F} \mathcal{A}^c.
\]

Since \( P \) and \( Q \) preserve weak equivalences and \( G \) preserves weak equivalences between fibrant objects, we conclude that \( G' \) carries \( \mathcal{W}_B \) into \( \mathcal{W}_A \), and therefore induces a map of marked simplicial sets

\[
g' : (N(\mathcal{B}^c), \mathcal{W}_B) \to (N(\mathcal{A}^c), \mathcal{W}_A).
\]

We claim that this map is homotopy inverse to \( f \). We will argue that \( g' \circ f \) is homotopic to the identity; the proof for \( f \circ g' \) is similar. We have a diagram of natural transformations

\[
id_{\mathcal{A}^c} \leftarrow P \circ (G \circ F) \to (P \circ G \circ Q) \circ F \simeq G' \circ F.
\]

It will therefore suffice to show that for every cofibrant object \( X \in \mathcal{A}^c \), the resulting maps

\[
X \xrightarrow{\eta_X} P(X) \xrightarrow{\epsilon} (G' \circ F)(X)
\]
are weak equivalences. For the map $u_X$, this is clear. The map $v_X$ fits into a commutative diagram

$$
\begin{array}{c}
P(X) \xrightarrow{v_X} (G' \circ F)(X) \\
\downarrow \quad \quad \downarrow \\
X \xrightarrow{v_X'} (G \circ Q \circ F)(X)
\end{array}
$$

where the vertical maps are weak equivalences. It will therefore suffice to show that $v_X'$ is a weak equivalence. Since $X$ is cofibrant and $(Q \circ F)(X)$ is a fibrant object of $\mathcal{B}$, our assumption that $F$ is a Quillen equivalence shows that $v_X'$ is a weak equivalence if and only if the adjoint map $F(X) \to (Q \circ F)(X)$ is a weak equivalence, which is clear.

It follows from the main result of [36] that every combinatorial model category is Quillen equivalent to a combinatorial simplicial model category. Combining this result, Lemma 1.3.4.21, Theorem 1.3.4.20, and Proposition T.A.3.7.6, we obtain the following:

**Proposition 1.3.4.22.** Let $\mathcal{A}$ be a combinatorial model category. Then the underlying $\infty$-category of $\mathcal{A}$ is presentable.

Similarly, Theorem T.4.2.4.1 implies the following:

**Proposition 1.3.4.23.** Let $\mathcal{A}$ be a combinatorial model category, let $I$ be a small category, let $F : I \to \mathcal{A}^c$ be a functor, and let $\alpha : \lim_{I \in I} F(I) \to X$ be a morphism in $\mathcal{A}^c$. The following conditions are equivalent:

1. The map $\alpha$ exhibits $X$ as a homotopy limit of the diagram $F$ (in the model category $\mathcal{A}$).
2. The induced map

$$
N(I)^\omega \to N(\mathcal{A}^c) \to N(\mathcal{A}^c)[W^{-1}]
$$

is a limit diagram in the underlying $\infty$-category $N(\mathcal{A}^c)[W^{-1}]$ of $\mathcal{A}$.

**Proposition 1.3.4.24.** Let $\mathcal{A}$ be a combinatorial model category, let $I$ be a small category, let $F : I \to \mathcal{A}^c$ be a functor, and let $\alpha : \lim_{I \in I} F(I) \to X$ be a morphism in $\mathcal{A}^c$. The following conditions are equivalent:

1. The map $\alpha$ exhibits $X$ as a homotopy colimit of the diagram $F$ (in the model category $\mathcal{A}$).
2. The induced map

$$
N(I)^\circ \to N(\mathcal{A}^c) \to N(\mathcal{A}^c)[W^{-1}]
$$

is a colimit diagram in the underlying $\infty$-category $N(\mathcal{A}^c)[W^{-1}]$ of $\mathcal{A}$.

Finally, by reducing to the simplicial case and invoking Proposition T.4.2.4.4, we obtain:

**Proposition 1.3.4.25.** Let $\mathcal{A}$ be a combinatorial model category and let $I$ be a small category. Let $\mathcal{A}^d$ be the category of functors from $I$ to $\mathcal{A}$ (endowed with either the injective or projective model structure), let $(\mathcal{A}^d)^c$ be the full subcategory of $\mathcal{A}^d$ spanned by the cofibrant objects, and let $W'$ be the collection of weak equivalences in $(\mathcal{A}^d)^c$. Then the evident map

$$
N(I) \times N((\mathcal{A}^d)^c) \to N(\mathcal{A}^c)
$$

induces an equivalence of $\infty$-categories

$$
N((\mathcal{A}^d)^c)[W'^{-1}] \to \text{Fun}(N(I), N(\mathcal{A})[W^{-1}]).
$$

**Corollary 1.3.4.26.** Let $F : \mathcal{A} \to \mathcal{B}$ be a left Quillen functor between combinatorial model categories. Let $\mathcal{A}^c$ and $\mathcal{B}^c$ denote the full subcategories of $\mathcal{A}$ and $\mathcal{B}$ spanned by the cofibrant objects, and let $W_A$ and $W_B$ be the collection of weak equivalences in $\mathcal{A}^c$ and $\mathcal{B}^c$, respectively. Then the induced functor $f : N(\mathcal{A}^c)[W_A^{-1}] \to N(\mathcal{B}^c)[W_B^{-1}]$ preserves small colimits.
Proof. In view of Proposition T.4.4.2.7, it will suffice to show that $f$ preserves small colimits indexed by $N(I)$, where $I$ is a small category. By virtue of Proposition 1.3.4.25, it suffices consider colimits of diagrams which arise from functors $I \to A^c$. This follows from Proposition 1.3.4.24, since $F$ preserves homotopy colimits.

\[ \square \]

**Remark 1.3.4.27.** Let $F : A \to B$ be as in Corollary 1.3.4.26. Using Proposition 1.3.4.22 and Corollary T.5.5.2.9, we conclude that the induced map of $\infty$-categories $f : N(A^c)[W_A^{-1}] \to N(B^c)[W_B^{-1}]$ admits a right adjoint $g$. It is not hard to construct $g$ explicitly, by composing a right adjoint to $F$ with a fibrant replacement functor in $B$ and a cofibrant replacement functor in $A$ (as in the proof of Lemma 1.3.4.21).

We conclude this section by giving the proof of Theorem 1.3.4.20.

**Proof of Theorem 1.3.4.20.** Let $A$ be a simplicial model category and let $\theta : N(A^c) \to N(A^o)$ be the functor determined by Lemma 1.3.4.19. Let $W$ be the collection of weak equivalences in $A^c$ and $W^o$ the collection of weak equivalences in $A^o$. We wish to show that $\theta$ induces a weak equivalence of marked simplicial sets $(N(A^c), W) \to (N(A^o), W^o)$. Let $\mathcal{C} = A^c$, regarded as a simplicial category, and let $\phi$ denote the composite map

$$ N(A^c) \xrightarrow{\theta} N(A^o) \to N(\mathcal{C}) $$

(here $|\mathcal{C}|$ denotes the topological category associated to $\mathcal{C}$, as in the proof of Proposition 1.3.4.7). There is an evident natural transformation $\phi' \to \phi$, where $\phi'$ is the inclusion $N(A^c) \subseteq N(\mathcal{C})$. It follows from Lemma 1.3.4.19 that this natural transformation is given by morphisms belonging to $W$, so that $\phi$ and $\phi'$ induce the same morphism $(N(A^c), W) \to (N(\mathcal{C}), W)$ in the homotopy category of marked simplicial sets. Proposition 1.3.4.7 implies that $\phi'$ determines a weak equivalence of marked simplicial sets, so that $\phi$ is also a weak equivalence of marked simplicial sets. It will therefore suffice to show that the composite map

$$ (N(A^o), W^o) \xrightarrow{\psi'} N(\mathcal{C}), W^o) \xrightarrow{\psi} (N(\mathcal{C}), W) $$

is a weak equivalence of marked simplicial sets. It is clear that $\psi'$ is a weak equivalence (since $A^o$ is a fibrant simplicial category). The argument above shows that $\psi \circ \psi'$ (and therefore also $\psi$) admits a right homotopy inverse. We will complete the proof by constructing a left homotopy inverse to $\psi$.

We claim that the inclusion $N(\mathcal{C}) \subseteq N(\mathcal{C})$ admits a left adjoint. To prove this, it suffices to show that for every cofibrant object $X \in A$, there exists a morphism $f : X \to Y$ where $Y \in A^o$ which induces a homotopy equivalence $\text{Map}_A(Y, Z) \to \text{Map}_A(X, Z)$ for each $Z \in A^o$. For this, it suffices to take $f$ to be any weak equivalence from $X$ to a fibrant-cofibrant object of $Y$. Let $L : N(\mathcal{C}) \to N(\mathcal{C})$ be a left adjoint to the inclusion. The above argument shows that the unit transformation $u : \text{id} \to L$ carries each cofibrant object $X \in A$ to a weak equivalence $f : X \to Y$ in $A$. It follows that $L$ carries $W$ into $W^o$, and therefore induces a map of marked simplicial sets $\zeta : (N(\mathcal{C}), W) \to (N(A^o), W^o)$ which is the desired left homotopy inverse to $\psi$.

**1.3.5 Grothendieck Abelian Categories**

In §1.3.3, we studied the right-bounded derived $\infty$-category $D^-(A)$ of an abelian category $A$ with enough projective objects. If $A$ instead has enough injective objects, then we can consider instead its left-bounded derived $\infty$-category $D^+(A) \simeq D^-(A^{op})^{op}$ (see Variant 1.3.2.8). For many applications, it is convenient to work with chain complexes which are unbounded in both directions. In this section, we will study an unbounded version of the derived $\infty$-category introduced in §1.3.3, following ideas introduced in [136]. We will discuss a variant of this construction in §1.3.6. We begin by singling out a convenient class of abelian categories to work with.

**Definition 1.3.5.1.** Let $A$ be an abelian category. We say that $A$ is Grothendieck if it is presentable and the collection of monomorphisms in $A$ is closed under small filtered colimits.
Remark 1.3.5.2. The notion of a Grothendieck abelian category was introduced by Grothendieck in the paper [64].

Proposition 1.3.5.3. Let $\mathcal{A}$ be a Grothendieck abelian category. Then $\text{Ch}(\mathcal{A})$ admits a left proper combinatorial model structure, which can be described as follows:

1. A map of chain complexes $f : M_\bullet \to N_\bullet$ is a cofibration if, for every integer $k$, the induced map $M_k \to N_k$ is a monomorphism in $\mathcal{A}$.

2. A map of chain complexes $f : M_\bullet \to N_\bullet$ is weakly saturated in the sense of Definition T.A.1.2.2. It is clear that the collection of cofibrations in $\text{Ch}(\mathcal{A})$ is the smallest weakly saturated class of morphisms containing $C_0$ which is weakly saturated, in the sense of Definition T.A.1.2.2. It is clear that the collection of cofibrations contains $C_0$ and is weakly saturated. Conversely, suppose we are given a cofibration of chain complexes $f : M_\bullet \to N_\bullet$. We define a compatible sequence of monomorphisms $f_\alpha : M(\alpha) \to N_\bullet$ by transfinite induction. Set $f_0 = f$, and for $\alpha$ a nonzero limit ordinal let $f_\alpha$ be the induced map $\lim_{\beta < \alpha} M(\beta) \to N_\bullet$ (our assumption that $\mathcal{A}$ is Grothendieck guarantees that this map is again a monomorphism).

Assume that $f_\alpha$ has been defined. We can choose a map $\lambda : X \to N_\bullet$ which does not factor through $M(\alpha)_\bullet$. Replacing $\lambda$ by the composite map $X \xrightarrow{\lambda} N_\bullet \xrightarrow{f_\alpha} N_{\alpha+1}$ if necessary, we may assume in addition that the composite map $d \circ \lambda : X \to N_{\alpha+1}$ does factor through $M(\alpha)_{\alpha+1}$. Let $X_0 = M(\alpha)_\bullet \times_{N_\bullet} X$ and let $\lambda : X_0 \to X$ be the projection onto the second factor. Then we have a commutative diagram

$$
\begin{array}{ccc}
E(u,n)_\bullet & \longrightarrow & E(\text{id}_X,n)_\bullet \\
\downarrow & & \downarrow \\
M(\alpha)_\bullet & \xrightarrow{f_\alpha} & N_\bullet.
\end{array}
$$

Taking $\text{Ch}(\alpha + 1)_\bullet$ to be the pushout $\text{Ch}(\alpha)_\bullet \coprod_{E(\alpha,n)_\bullet} E(\text{id}_X,n)_\bullet$, we obtain a monomorphism $f_{\alpha+1} : \text{Ch}(\alpha + 1)_\bullet \to N_\bullet$ compatible with $\alpha$. Moreover, the map $\lambda$ factors through $f_{\alpha+1}$, so that $M(\alpha)_\bullet$ and $M(\alpha + 1)_\bullet$ are not isomorphic as subobjects of $N_\bullet$.

Since the collection of subobjects of $N_\bullet$ is bounded, this process must eventually terminate. In other words, for $\alpha$ sufficiently large, the map $f_\alpha$ is an equivalence. This implies that the map $f$ can be obtained as a transfinite composition of monomorphisms $M(\beta)_\bullet \to M(\beta + 1)_\bullet$, each of which is a pushout of a morphism belonging to $C_0$. It follows that $f$ belongs to the smallest weakly saturated class of morphisms containing $C_0$, as desired.

To complete the proof, it will suffice to show that the class of cofibrations and weak equivalences satisfy the hypotheses of Proposition T.A.2.6.13:
The class of weak equivalences is perfect. To prove this, we note that a morphism \( f : M_s \to N_s \) is a weak equivalence if and only if its image under the homology functor \( H_* : \text{Ch}(A) \to \prod_{n \in \mathbb{Z}} A \) is an isomorphism. Since \( A \) is a Grothendieck abelian category, the functor \( H_* \) commutes with filtered colimits and the result follows from Corollary T.A.2.6.12.

(2) Suppose we are given a pushout diagram of chain complexes \( \sigma : \)

\[
\begin{array}{ccc}
M'_s & \xrightarrow{f} & M_s \\
\downarrow{g} & & \downarrow{g'} \\
N'_s & \xrightarrow{f'} & N_s
\end{array}
\]

where \( f \) is a cofibration and \( g \) is a weak equivalence; we must show that \( g' \) is a weak equivalence. For every integer \( n \), we have a map of exact sequences

\[
\begin{array}{cccc}
H_{n+1}(M/M') & \xrightarrow{h_0} & H_n(M) & \xrightarrow{h_2} & H_{n-1}(M') \\
\downarrow{h_1} & & \downarrow{h_3} & & \downarrow{h_4} \\
H_{n+1}(N/N') & \xrightarrow{k_0} & H_n(N) & \xrightarrow{k_3} & H_{n-1}(N').
\end{array}
\]

Since \( g \) is a quasi-isomorphism, the maps \( \theta_1 \) and \( \theta_3 \) are isomorphisms. The maps \( \theta_2 \) and \( \theta_4 \) are induced by the map of chain complexes \( (M/M')_* \to (N/N')_* \), which is an isomorphism because \( \sigma \) is assumed to be a pushout diagram. It follows that \( \theta_2 \) is also an isomorphism, as desired.

(3) Let \( f : M_s \to N_s \) be a map of chain complexes which has the right lifting property with respect to every cofibration. We must show that \( f \) is a quasi-isomorphism. Fix an integer \( n \) and let \( Z \) denote the kernel of the differential \( d : N_n \to N_{n-1} \). Let \( Z[n] \) denote the chain complex consisting of the object \( Z \in A \), concentrated in degree \( n \). Then the inclusion \( 0 \to Z[n] \) is a cofibration, so that \( f \) has the right lifting property with respect to \( f \). It follows that the monomorphism \( Z[n] \to N_n \) lifts to a map \( Z \to Z' \), where \( Z' \) denotes the kernel of the differential \( M_n \to M_{n-1} \). This guarantees that the map on homology \( \theta : H_n(M) \to H_n(N) \) is an epimorphism. We now show that \( \theta \) is a monomorphism. To prove this, let \( Z'' \) denote the fiber product \( Z' \times_{N_n} N_{n+1} \), and let \( u : 0 \to Z'' \) be the zero map. Then \( f \) has the right lifting property with respect to the cofibration \( E(u, n+1)_* \to E(id_{Z''}, n+1)_* \). It follows that there exists a map \( \mu : Z'' \to M_{n+1} \) such that \( Z'' \xrightarrow{\mu} M_{n+1} \xrightarrow{d} N_{n+1} \) is given by the projection onto the second factor, and the map \( Z'' \xrightarrow{\mu} M_{n+1} \xrightarrow{d} M_n \) is given by the projection onto the first factor \( Z' \) (which we view as a subobject of \( M_n \)). We note that \( Z'' \) is given by the fiber product \( Z \times_{H_n(M)} \text{ker}(\theta) \), so the map \( Z'' \to \text{ker}(\theta) \) is an epimorphism. However, the existence of the map \( \mu \) shows that the map \( Z'' \to \text{ker}(\theta) \) is zero, so that \( \theta \) is a monomorphism as desired.

\[ \square \]

**Warning 1.3.5.4.** Let \( A \) be a Grothendieck abelian category. The category \( \text{Ch}(A) \) is endowed with both a model structure and a simplicial enrichment (via Construction 1.3.1.13). However, it is not a simplicial model category in the sense of Definition T.A.3.1.5, because it is not tensored over the category of simplicial sets. For every simplicial set \( K \) and any pair of objects \( M_s, M'_s \in \text{Ch}(A) \), we have a canonical bijection

\[
\text{Hom}_{\text{Ch}(A)}(N_*(K) \otimes M_s, M'_s) \simeq \text{Hom}_{\text{Set}_\Delta}(K, \text{Map}_{\text{Ch}(A)_\Delta}(M_s, M'_s)).
\]

This bijection extends to a map of simplicial sets

\[
\text{Map}_{\text{Ch}(A)_\Delta}(N_*(K) \otimes M_s, M'_s) \to \text{Map}_{\text{Set}_\Delta}(K, \text{Map}_{\text{Ch}(A)}(M_s, M'_s)),
\]

which is generally not an isomorphism (because the Alexander-Whitney map \( N_*(K \times K') \to N_*(K) \otimes N_*(K') \) generally fails to be an isomorphism).
1.3. HOMOLOGICAL ALGEBRA AND DERIVED CATEGORIES

Remark 1.3.5.5. In the situation of Proposition 1.3.5.3, the collection of weak equivalences in \( \text{Ch}(\mathcal{A}) \) is closed under filtered colimits (since the formation of homology commutes with filtered colimits).

If \( \mathcal{A} \) is a Grothendieck abelian category, then every object of \( \text{Ch}(\mathcal{A}) \) is cofibrant. Our next goal is to say something about the fibrant objects.

Proposition 1.3.5.6. Let \( \mathcal{A} \) be a Grothendieck abelian category and let \( M_\ast \in \text{Ch}(\mathcal{A}) \) be a chain complex. If \( M_\ast \) is fibrant (with respect to the model structure described in Proposition 1.3.5.3), then each \( M_n \) is an injective object of \( \mathcal{A} \). Conversely, if each \( M_n \) is injective and \( M_n \simeq 0 \) for \( n \gg 0 \), then \( M_\ast \) is a fibrant object of \( \text{Ch}(\mathcal{A}) \).

Corollary 1.3.5.7 (Grothendieck). Let \( \mathcal{A} \) be a Grothendieck abelian category. Then \( \mathcal{A} \) has enough injective objects: that is, for every object \( M \in \mathcal{A} \), there exists a monomorphism \( M \to Q \), where \( Q \in \mathcal{A} \) is injective.

Proof. Let \( M[0] \) denote the chain complex consisting of object \( M \in \mathcal{A} \), concentrated in degree zero. Choose a trivial cofibration \( M[0] \to Q_\ast \), where \( Q_\ast \in \text{Ch}(\mathcal{A}) \) is fibrant. Then the induced map \( M \to Q_0 \) is a monomorphism, and \( Q_0 \in \mathcal{A} \) is injective by Proposition 1.3.5.6.

Proof of Proposition 1.3.5.6. For every object \( X \in \mathcal{A} \), we let \( E(X, n)_\ast \) denote the chain complex given by

\[
E(X, n)_k = \begin{cases} X & \text{if } k \in \{n, n-1\} \\ 0 & \text{otherwise,} \end{cases}
\]

where the differential is given by the identity map \( \text{id}_X : X \to X \). If \( X \to Y \) is a monomorphism in \( \mathcal{A} \), then the induced map \( i : E(X, n)_\ast \to E(Y, n)_\ast \) is a trivial cofibration in \( \text{Ch}(\mathcal{A}) \). If \( M_\ast \) is fibrant, then \( M_n \) has the extension property with respect to \( i \), so that every map \( X \to M_n \) extends to a map \( Y \to M_n \); this proves that \( M_n \) is injective.

Conversely, suppose that each \( M_n \) is injective and that \( M_n \simeq 0 \) for \( n \gg 0 \). We wish to show that \( M_\ast \) is fibrant. Choose a trivial cofibration \( u : A_\ast \to A_\ast' \) and suppose we are given a chain map \( f : A_\ast \to M_\ast' \); we must show that \( f \) can be extended to a chain map \( f' : A_\ast' \to M_\ast' \). For each \( n \in \mathbb{Z} \), we let \( Z_n(A) \) denote the kernel of the differential \( A_n \to A_{n-1} \) and \( B_n(A) \) the image of the differential \( A_{n+1} \to A_n \), let \( A(n)_\ast \) denote the chain complex

\[
\cdots \to A_{n+2} \to A_{n+1} \to B_n(A) \to A_0 \to \cdots,
\]
and let \( f_n = f|A(n)_\ast \). We define \( B_n(A')_\ast \), \( Z_n(A')_\ast \), and \( A'(n)_\ast \), similarly. For \( n \gg 0 \), the map \( f_n \) is zero and therefore extends to a map \( f'_n : A'(n)_\ast \to M_\ast' \). We will construct a compatible sequence of maps \( \{f'_n : A'(i)_n \to M_\ast'\}_{i \leq n} \) extending the map \( f_n \); passing to the limit, we will obtain the desired chain map \( f' : A'_\ast \to M_\ast' \) extending \( f \). Assume therefore that \( i \leq n \) and that the map \( f'_i \) has already been constructed. We show that it is possible to construct a chain map \( f'_{i-1} : A'(i-1)_\ast \to M_\ast' \) which extends both \( f'_i \) and \( f_{i-1} \). Our assumption that \( u \) is a quasi-isomorphism guarantees that the diagram

\[
\begin{array}{ccc}
B_i(A) & \longrightarrow & Z_i(A) \\
\downarrow & & \downarrow \\
B_i(A') & \longrightarrow & Z_i(A')
\end{array}
\]

is a pushout square in \( \mathcal{A} \), so that the maps \( f|Z_i(A) \) and \( f'_i|B_n(A') \) determine a unique map \( g : Z_i(A') \to M_i \). The map \( g \) carries \( Z_i(A) \) into the kernel of the differential \( d : M_i \to M_{i-1} \) (since \( f \) is a chain map) and \( B_i(A') \) into the image of the differential \( M_{i+1} \to M_i \) (since \( f'_i \) is a chain map). Since \( B_i-1(A') \simeq A'(n)/Z_nA' \), we conclude that giving a chain map \( f'_{i-1} : A'(i)_n \to M_\ast' \) compatible with both \( f'_i \) and \( g \) is equivalent to choosing a map \( \overline{g} : A'_i \to M_i \) extending \( g \). To complete the construction, we must show that it is possible to choose \( \overline{g} \) so that the composite map

\[
A_i \xrightarrow{u_i} A'_i \xrightarrow{\overline{g}} M_i
\]

is given by \( f \). We note that \( f \) and \( g \) determine a map

\[
\overline{g}_0 : A_i \coprod_{Z_i(A)} Z_i(A') \to M_i.
\]
Since $M_i$ is an injective object of $\mathcal{A}$, to prove the existence of $\bar{g}$ it will suffice to show that the map \[ \theta : A_i \coprod_{Z_i(A')} Z_i(A') \to A'_i \] is a monomorphism. This map fits into a diagram of short exact sequences

\[
\begin{array}{ccccccccc}
0 & \to & Z_i(A') & \to & A_i \coprod_{Z_i(A')} Z_i(A') & \to & B_{i-1}(A) & \to & 0 \\
& & \downarrow \theta' & & \downarrow \theta & & \downarrow \theta'' & & \\
0 & \to & Z_i(A') & \to & A'_i & \to & B_{i-1}(A') & \to & 0
\end{array}
\]

The map $\theta'$ is an isomorphism and the map $\theta''$ is a monomorphism (since $u$ is a cofibration), so that $\theta$ is a monomorphism by the snake lemma.

**Definition 1.3.5.8.** Let $\mathcal{A}$ be a Grothendieck abelian category. We let $\text{Ch}(\mathcal{A})^o$ denote the full subcategory of $\text{Ch}(\mathcal{A})$ spanned by the fibrant objects (which are automatically cofibrant). We let $\mathcal{D}(\mathcal{A})$ denote the differential graded nerve $N_{\text{dg}}(\text{Ch}(\mathcal{A})^o)$. We will refer to $\mathcal{D}(\mathcal{A})$ as the derived $\infty$-category of $\mathcal{A}$.

**Proposition 1.3.5.9.** Let $\mathcal{A}$ be a Grothendieck abelian category. Then the $\infty$-category $\mathcal{D}(\mathcal{A})$ is stable.

**Proof.** The $\infty$-category $N_{\text{dg}}(\text{Ch}(\mathcal{A}))$ is stable, by Proposition 1.3.2.10. It will therefore suffice to show that $\mathcal{D}(\mathcal{A})$ is a stable subcategory of $N_{\text{dg}}(\text{Ch}(\mathcal{A}))$. Since $\mathcal{D}(\mathcal{A})$ is evidently invariant under translation, it will suffice to show that it is closed under taking cofibers. For this, it suffices to show that if $f : M_* \to N_*$ is a map between fibrant objects of $\text{Ch}(\mathcal{A})$, then the mapping cone $C_*(f)$ of $f$ is also a fibrant object of $\text{Ch}(\mathcal{A})$. Since $M_*[1]$ is fibrant, it suffices to show that the epimorphism of chain complexes $C_*(f) \to M_*[1]$ is a fibration. For this, we must show that every lifting problem of the form

\[
\begin{array}{ccc}
A_* & \longrightarrow & C_*(f) \\
\downarrow \iota & & \downarrow \pi \\
B_* & \longrightarrow & M_*[1]
\end{array}
\]

has a solution, provided that $\iota$ is both a monomorphism and a quasi-isomorphism. To prove this, it suffices to show that the chain complex $N_*[1]$ has the right lifting property with respect to the monomorphism $j : C_*(i) \hookrightarrow C_*(\text{id}_B)$. This follows from our assumption that $N_*$ is fibrant, since $j$ is a trivial cofibration in $\text{Ch}(\mathcal{A})$.

**Remark 1.3.5.10.** Let $\mathcal{A}$ be a Grothendieck abelian category. Then $\mathcal{A}$ has enough injectives (Corollary 1.3.5.7), so that the $\infty$-category $\mathcal{D}(\mathcal{A})^+$ is defined as in Variant 1.3.2.8. The characterization of the fibrant objects of $\text{Ch}(\mathcal{A})$ supplied by Proposition 1.3.5.6 implies that $\mathcal{D}(\mathcal{A})^+$ is a full subcategory of $\mathcal{D}(\mathcal{A})$.

**Lemma 1.3.5.11.** Let $\mathcal{A}$ be a Grothendieck abelian category. If $M_* \in \text{Ch}(\mathcal{A})$ is acyclic and $Q_* \in \text{Ch}(\mathcal{A})$ is fibrant, then the chain complex $\text{Map}_{\text{Ch}(\mathcal{A})}(M_*, Q_*)$ is acyclic.

**Proof.** Let $\eta$ be an $n$-cycle in $\text{Map}_{\text{Ch}(\mathcal{A})}(M_*, Q_*)$, given by a map of chain complexes $f_0 : M_*[-n] \to Q_*$. Let $C_*$ denote the cone on $M_*[-n]$. To prove that $\eta$ is homologous to zero, it will suffice to show that $f_0$ extends to a map $f : C_* \to Q_*$. Since $Q_*$ is fibrant, we are reduced to proving that the inclusion $j : M_*[-n] \to C_*$ is a trivial cofibration. The map $j$ is evidently a monomorphism; it is a quasi-isomorphism by virtue of our assumption that $M_*$ is acyclic (which implies that the complexes $M_*[-n]$ and $C_*$ are also acyclic).

**Lemma 1.3.5.12.** Let $\mathcal{A}$ be a Grothendieck abelian category and let $f : M'_* \to M_*$ be a trivial cofibration in $\text{Ch}(\mathcal{A})$. For every fibrant object $Q_* \in \text{Ch}(\mathcal{A})$, the induced map \[ \theta : \text{Map}_{\text{Ch}(\mathcal{A})}(M'_*, Q_*) \to \text{Map}_{\text{Ch}(\mathcal{A})}(M_*, Q_*) \] is a quasi-isomorphism of chain complexes.
Proof. Proposition 1.3.5.6 implies that each \( Q_n \) is injective, so that each of the maps \( \text{Hom}_A(M_p, Q_n) \to \text{Hom}_A(M_p', Q_n) \) is surjective. It follows that \( \theta \) is a surjection of chain complexes. It will therefore suffice to show that the chain complex \( \ker(\theta) \simeq \text{Map}_{\text{Ch}(A)}((M/M')\ast, Q_n) \) is acyclic. This follows from Lemma 1.3.5.11 (the complex \( (M/M')\ast \) is acyclic by virtue of our assumption that \( f \) is a quasi-isomorphism).

**Proposition 1.3.5.13.** Let \( A \) be a Grothendieck abelian category. Then \( \mathcal{D}(A) \) is a localization of the \( \infty \)-category \( N_{dg}(\text{Ch}(A)) \).

Proof. For every object \( M_\ast \in \text{Ch}(A) \), we can choose a trivial cofibration \( f : M_\ast \to Q_\ast \), where \( Q_\ast \) is fibrant. Lemma 1.3.5.12 implies that \( f \) exhibits \( Q_\ast \) as a \( \mathcal{D}(A) \)-localization of \( M_\ast \).

**Proposition 1.3.5.14.** Let \( A \) be a Grothendieck abelian category and let \( f : M_\ast \to M'_\ast \) be a map of chain complexes. If \( f \) is a quasi-isomorphism and \( Q_\ast \in \text{Ch}(A) \) is fibrant, then \( f \) induces a quasi-isomorphism \( \theta : \text{Map}_{\text{Ch}(A)}(M_\ast, Q_\ast) \to \text{Map}_{\text{Ch}(A)}(M'_\ast, Q_\ast) \). In particular, if \( f \) is a quasi-isomorphism between fibrant chain complexes, then \( f \) is a chain homotopy equivalence (and therefore induces an equivalence in \( \mathcal{D}(A) \)).

Proof. The map \( f \) admits a factorization

\[
M_\ast \xrightarrow{f'} M''_\ast \xrightarrow{f''} M'_\ast
\]

where \( f' \) is a trivial cofibration in \( \text{Ch}(A) \) and \( f'' \) is a trivial fibration in \( \text{Ch}(A) \). We may therefore assume either that \( f \) is a trivial cofibration or a trivial fibration. If \( f \) is a trivial cofibration, the result follows from Lemma 1.3.5.12. If \( f \) is a trivial fibration, then it admits a section \( s \) (since \( M'_\ast \) is cofibrant). The map \( s \) is then a trivial cofibration, and therefore induces a quasi-isomorphism \( \text{Map}_{\text{Ch}(A)}(M_\ast, Q_\ast) \to \text{Map}_{\text{Ch}(A)}(M'_\ast, Q_\ast) \) which is left inverse to \( \theta \), so that \( \theta \) is also a quasi-isomorphism.

Our next goal is to prove that the derived \( \infty \)-category \( \mathcal{D}(A) \) can be identified with the underlying \( \infty \)-category of the model category \( \text{Ch}(A) \), in the sense of Definition 1.3.4.15: that is, we can regard \( \mathcal{D}(A) \) as the \( \infty \)-category obtained from the ordinary category of chain complexes over \( A \) by inverting quasi-isomorphisms. This does not follow formally from Theorem 1.3.4.20, because \( \text{Ch}(A) \) is not a simplicial model category (Warning 1.3.5.4). Nevertheless, we have the following result:

**Proposition 1.3.5.15.** Let \( A \) be a Grothendieck abelian category, and let \( A \) denote the category of chain complexes \( \text{Ch}(A) \), regarded as a discrete category. Then the composite map \( N(A) \to N_{dg}(\text{Ch}(A)) \to \mathcal{D}(A) \) exhibits \( \mathcal{D}(A) \) as the underlying \( \infty \)-category of the model category \( A \); here \( L : N_{dg}(\text{Ch}(A)) \to \mathcal{D}(A) \) denotes a left adjoint to the inclusion \( \mathcal{D}(A) \hookrightarrow N_{dg}(\text{Ch}(A)) \).

Proof. Let \( A^\circ \) be the full subcategory of \( A \) spanned by the fibrant chain complexes, and let \( W \) be the collection of weak equivalences in \( A^\circ \). It is easy to see that \( A^\circ \) is closed under tensor product by the finite chain complex \( N_\ast(\Delta^1) \) (note that tensor product with \( N_\ast(\Delta^1) \) is a right Quillen functor, since it is right adjoint to the left Quillen functor given by tensor product with the dual chain complex \( N_\ast(\Delta^1) \)). Using Propositions 1.3.5.14 and 1.3.4.5, we deduce that the map \( N(A^\circ)[W^{-1}] \to \mathcal{D}(A) \) is an equivalence of \( \infty \)-categories. This is equivalent to the asserted result, by virtue of Remark 1.3.4.16.

**Definition 1.3.5.16.** Let \( A \) be a Grothendieck abelian category. For each integer \( n \), we let \( N_{dg}(\text{Ch}(A)) \geq n \) denote the full subcategory of \( N_{dg}(\text{Ch}(A)) \) spanned by those chain complexes \( M_\ast \) such that \( H_k(M) \simeq 0 \) for \( k < n \), and \( N_{dg}(\text{Ch}(A)) \leq n \) the full subcategory of \( N_{dg}(\text{Ch}(A)) \) spanned by those chain complexes \( M_\ast \) such that \( H_k(M) \simeq 0 \) for \( k > n \). Set

\[
\mathcal{D}(A) \geq n = N_{dg}(\text{Ch}(A)) \geq n \cap \mathcal{D}(A) \quad \mathcal{D}(A) \leq n = N_{dg}(\text{Ch}(A)) \leq n \cap \mathcal{D}(A).
\]

**Remark 1.3.5.17.** In the situation of Definition 1.3.5.16, suppose we are given an object \( M_\ast \in \mathcal{D}(A) \leq n \). Then there exists an equivalence \( M_\ast \simeq M'_\ast \) in \( \mathcal{D}(A) \leq n \), where \( M_k \simeq 0 \) for \( k > n \). To prove this, we
note that our assumption that \( H_k(M) \simeq 0 \) for \( k > n \) implies that the canonical map \( M_* \to \tau_{\leq n}M_* \) is a quasi-isomorphism, where \( \tau_{\leq n}M_* \) denotes the truncated chain complex
\[
\cdots \to 0 \to M_n/d(M_{n+1}) \to M_{n-1} \to M_{n-2} \to \cdots
\]
This complex may not be fibrant, but the fact that \( \mathcal{A} \) has enough injectives (Corollary 1.3.5.7) guarantees that we can construct a quasi-isomorphism \( \tau_{\leq n}M_* \to M'_* \), where \( M'_k \simeq 0 \) for \( k > n \) and each \( M'_k \) is injective (see the proof of Proposition 1.3.2.19). Then \( M'_* \) is fibrant by Proposition 1.3.5.6, and the composite map \( M_* \to \tau_{\leq n}M_* \to M'_* \) is a quasi-isomorphism.

**Proposition 1.3.5.18.** Let \( \mathcal{A} \) be a Grothendieck abelian category. Then the full subcategories
\[
N_{dg}(\text{Ch}(\mathcal{A}))_{\geq 0}, N_{dg}(\mathcal{A}) \leq 0 \subseteq N_{dg}(\text{Ch}(\mathcal{A}))
\]
determine a t-structure on the stable \( \infty \)-category \( N_{dg}(\text{Ch}(\mathcal{A})) \).

**Proof.** Fix any object \( M_* \in \text{Ch}(\mathcal{A}) \). Let \( X_* \) be the truncated chain complex
\[
\cdots \to 0 \to M_{-1}/d(M_0) \to M_{-2} \to M_{-3} \to \cdots
\]
and choose a quasi-isomorphism \( X_* \to M''_* \), where \( M''_* \) is a chain complex of injective objects of \( \mathcal{A} \) and \( M''_k \simeq 0 \) for \( k \geq 0 \). Let \( f : M_* \to M''_* \) be the composite map and let \( M'_* \) denote the shifted mapping cone \( C(f)[-1] \). We have a termwise split exact sequence of chain complexes
\[
M'_*[-1] \to M'_* \to M_*
\]
which gives a fiber sequence
\[
M'_* \to M_* \to M''_*
\]
in \( N_{dg}(\text{Ch}(\mathcal{A})) \), where \( M'_* \in N_{dg}(\text{Ch}(\mathcal{A}))_{\geq 0} \) and \( M''_* \in \mathcal{D}(\mathcal{A})_{\leq -1} \). To complete the proof, it will suffice to show that if \( M_* \in N_{dg}(\text{Ch}(\mathcal{A}))_{\geq 0} \) and \( Q_* \in \mathcal{D}(\mathcal{A})_{\leq -1} \), then the mapping space \( \text{Map}_{\text{Ch}(\mathcal{A})}(M_* , Q_* ) \) is contractible. In view of Remark 1.3.5.17, we may assume without loss of generality that \( Q_k \simeq 0 \) for \( k \geq 0 \). Let \( Y_* \) denote the chain complex
\[
\cdots \to M_2 \to M_1 \to \ker(d : M_0 \to M_{-1}) \to 0 \to \cdots
\]
Since \( M_* \in N_{dg}(\text{Ch}(\mathcal{A}))_{\geq 0} \), the monomorphism \( Y_* \to M_* \) is a quasi-isomorphism. It follows from Lemma 1.3.5.12 that the map
\[
\text{Map}_{\text{Ch}(\mathcal{A})}(M_* , Q_* ) \to \text{Map}_{\text{Ch}(\mathcal{A})}(Y_* , Q_* )
\]
is a quasi-isomorphism, so that \( \text{Map}_{N_{dg}(\text{Ch}(\mathcal{A}))}(M_* , Q_* ) \simeq \text{Map}_{N_{dg}(\text{Ch}(\mathcal{A}))}(Y_* , Q_* ) \) is a contractible Kan complex.

**Remark 1.3.5.19.** Let \( \mathcal{A} \) be a Grothendieck abelian category and suppose that \( M_* \in N_{dg}(\text{Ch}(\mathcal{A}))_{\geq 0} \) and \( Q_* \in \mathcal{D}(\mathcal{A})_{\leq 0} \). Then the canonical map
\[
\text{Map}_{N_{dg}(\text{Ch}(\mathcal{A}))}(M_* , Q_* ) \to \text{Hom}_\mathcal{A}(H_0(M) , H_0(Q))
\]
is a homotopy equivalence. To see this, we use Remark 1.3.5.17 to reduce to the case where \( Q_* \in \text{Ch}(\mathcal{A})_{\leq 0} \), and Lemma 1.3.5.12 to reduce to the case where \( M_* \in \text{Ch}(\mathcal{A})_{\geq 0} \), in which case the result is obvious. It follows that the functor \( M \mapsto H_0(M) \) induces an equivalence of abelian categories \( N_{dg}(\text{Ch}(\mathcal{A}))^0 \to \mathcal{A} \) (the homotopy inverse functor can be described as assigning to each object \( M \in \mathcal{A} \) an injective resolution of \( M \).

**Definition 1.3.5.20.** Let \( \mathcal{C} \) be a stable \( \infty \)-category which admits small filtered colimits. We will say that a t-structure \((\mathcal{C}\geq 0, \mathcal{C}\leq 0)\) on \( \mathcal{C} \) is **compatible with filtered colimits** if \( \mathcal{C}\leq 0 \) is closed under small filtered colimits in \( \mathcal{C} \).
Proposition 1.3.5.21. Let $A$ be a Grothendieck abelian category. Then:

1. The $\infty$-category $D(A)$ is presentable.
2. The pair of subcategories $(D(A)_{\geq 0}, D(A)_{\leq 0})$ determines a t-structure on $D(A)$.
3. The t-structure of (2) is accessible, right complete, and compatible with filtered colimits.

Proof. Assertion (1) follows from Propositions 1.3.5.15 and 1.3.4.22, and assertion (2) is an immediate consequence of Proposition 1.3.5.18. To prove (3), we note an object of $D(A)$ belongs to $D(A)_{\leq 0}$ if and only if its image under the homology functor $\prod_{n \geq 0} H_n : D(A) \to (\prod_{n \geq 0} N(A))$ vanishes. Using Propositions 1.3.4.24, 1.3.4.25, and our assumption that filtered colimits in $A$ are left exact, we conclude that each of the functors $H_n$ commutes with filtered colimits. It is now obvious that $D(A)_{\leq 0}$ is closed under filtered colimits, and Proposition T.5.4.6.6 guarantees that $D(A)_{\leq 0}$ is accessible. The right completeness of $D(A)$ follows from the dual of Proposition 1.2.1.19. \hfill \Box

Warning 1.3.5.22. The stable $\infty$-category $D(A)$ is generally not left complete.

Remark 1.3.5.23. Let $\mathcal{C}$ be a presentable stable $\infty$-category equipped with an accessible t-structure (see Definition 1.4.4.12) which is compatible with filtered colimits. Then the heart $\mathcal{C}^\circ$ is a presentable abelian category, and the canonical map $N(\mathcal{C}^\circ) \to \mathcal{C}$ preserves filtered colimits. If $\{f_\alpha : A_\alpha \to B_\alpha\}$ is a filtered diagram of monomorphisms in $\mathcal{C}^\circ$, then we have a filtered diagram of fiber sequences

$$A_\alpha \to B_\alpha \to B_\alpha/A_\alpha$$

in $\mathcal{C}$. Passing to filtered colimits, we obtain an fiber sequence

$$A \to B \to B/A$$

where $A$, $B$, and $B/A$ belong to the heart of $\mathcal{C}$, so that $f = \varinjlim f_\alpha$ is again a monomorphism. It follows that $\mathcal{C}^\circ$ is a Grothendieck abelian category.

Assume that $\bigcap_{n \geq 0} \mathcal{C}^\leq -n$ contains only zero objects of $\mathcal{C}$. Using Proposition 1.2.1.19, we conclude that $\mathcal{C}$ is right complete. It follows from Theorem 1.3.3.2 and Remark 1.3.3.6 that the inclusion $N(\mathcal{C}^\circ) \subseteq \mathcal{C}$ extends in an essentially unique way to a t-exact functor $D^+(\mathcal{C}^\circ) \to \mathcal{C}$.

Suppose that $A$ is a Grothendieck abelian category with enough projective objects (for example, the category of $R$-modules for some ring $R$). Then, in addition to the derived $\infty$-category $D(A)$, we can consider the derived $\infty$-category $D^-(A)$ introduced in Definition 1.3.2.7. These two $\infty$-categories are a priori quite different from one another: one is defined using complexes of injective objects of $A$, the other using complexes of projective objects of $A$. Nevertheless we have the following result:

Proposition 1.3.5.24. Let $A$ be a Grothendieck abelian category with enough projective objects, and let $L : N_{dg}(Ch(A)) \to D(A)$ be a left adjoint to the inclusion. Then the composite functor

$$F : D^-(A) \hookrightarrow N_{dg}(Ch(A)) \overset{L}{\to} D(A)$$

is a fully faithful embedding, whose essential image is the subcategory $\bigcup_{n \geq 0} D(A)_{\geq -n} \subseteq D(A)$.

Proof. Let $M_*, M'_* \in D^-(A)$. We will show that the composite map

$$\text{Map}_{Ch(A)}(M_*, M'_*) \overset{\theta}{\to} \text{Map}_{Ch(A)}(M_*, LM'_*) \overset{\theta'}{\to} \text{Map}_{Ch(A)}(LM_*, LM'_*)$$

is a quasi-isomorphism of chain complexes of abelian groups. The map $\theta$ is a quasi-isomorphism by Lemma 1.3.2.20, and the definition of $L$ guarantees that $\theta'$ is a quasi-isomorphism. This proves that $F$ is fully faithful. It is obvious that the essential image of $F$ is contained in $\bigcup_{n \geq 0} D(A)_{\geq -n}$. Conversely, suppose that $M_* \in D(A)_{\geq -n}$. Since $A$ has enough projective objects, we can choose an object $P_* \in D^-(A)$ and a quasi-isomorphism from $P_*$ to the subcomplex

$$\cdots \to M_{-n} \to \ker(d : M_{-n} \to M_{-n-1}) \to 0 \to \cdots$$

of $M_*$. Using Lemma 1.3.2.20, we conclude that $M_* \simeq LP_*$ belongs to the essential image of $L$. \hfill \Box
1.3.6 Complexes of Injective Objects

Let $\mathcal{A}$ be an abelian category with enough injective objects. In §1.3.2 we introduced the derived $\infty$-category $\mathcal{D}^+(\mathcal{A})$, whose objects are left-bounded chain complexes of injective objects of $\mathcal{A}$. The restriction to left-bounded complexes is sometimes overly restrictive: for example, the category $\mathcal{D}^+(\mathcal{A})$ generally does not admit infinite limits and colimits, even if the abelian category $\mathcal{A}$ is well-behaved. We can attempt to correct this defect by enlarging the $\infty$-category $\mathcal{D}^+(\mathcal{A})$. For example, if $\mathcal{A}$ is a Grothendieck abelian category, we can replace $\mathcal{D}^+(\mathcal{A})$ by the larger $\infty$-category $\mathcal{D}(\mathcal{A})$ introduced in §1.3.5. The $\infty$-category $\mathcal{D}(\mathcal{A})$ is presentable (Proposition 1.3.5.21), and therefore admits small limits and colimits. However, for some purposes it is more convenient to work with a different enlargement of $\mathcal{D}(\mathcal{A})$. For example, if $\mathcal{A}$ is a locally Noetherian abelian category (see Definition 1.3.6.5), then $\mathcal{D}^+(\mathcal{A})$ is equipped with a good supply of “finite” objects: namely, those chain complexes $Q_\bullet$ whose homologies $H_n(Q_\bullet)$ are compact objects of $\mathcal{A}$, which vanish for almost every $n \in \mathbb{Z}$. The collection of chain complexes satisfying this condition span a full subcategory $\mathcal{D}_0 \subseteq \mathcal{D}^+(\mathcal{A})$. We will prove below that $\mathcal{D}^+(\mathcal{A})$ can be identified with a full subcategory of $\mathcal{D}(\mathcal{A})$. In particular, we can regard $\text{Ind}(\mathcal{D}_0)$ as an enlargement of $\mathcal{D}^+(\mathcal{A})$. The $\infty$-category $\text{Ind}(\mathcal{D}_0)$ is not only presentable: it is compactly generated, which is often very useful in applications. Our goal in this section is to study the $\infty$-category $\text{Ind}(\mathcal{D}_0)$. Following work of Krause ([90]), we show that this $\infty$-category admits an explicit description in terms of homological algebra: namely, it can be identified with the differential graded nerve of $\text{Ch}(\mathcal{A}_{\text{inj}})$, where $\mathcal{A}_{\text{inj}}$ denotes the full subcategory $\mathcal{A}$ spanned by the injective objects (Theorem 1.3.6.7).

**Definition 1.3.6.1.** Let $\mathcal{A}$ be a Grothendieck abelian category, and let $\mathcal{A}_{\text{inj}}$ denote the full subcategory of $\mathcal{A}$ spanned by the injective objects. We let $\mathcal{D}^{\text{inj}}(\mathcal{A})$ denote the $\infty$-category $\text{N}_{dg}(\text{Ch}(\mathcal{A}_{\text{inj}}))$.

**Proposition 1.3.6.2.** Let $\mathcal{A}$ be a Grothendieck abelian category. Then:

1. The $\infty$-category $\mathcal{D}^{\text{inj}}(\mathcal{A})$ is stable.
2. The $\infty$-category $\mathcal{D}^{\text{inj}}(\mathcal{A})$ contains $\mathcal{D}(\mathcal{A})$ as a full subcategory.
3. Let $\mathcal{D}^{\text{inj}}(\mathcal{A}) \geq 0$ denote the intersection $\mathcal{D}^{\text{inj}}(\mathcal{A}) \cap \mathcal{N}_{dg}(\text{Ch}(\mathcal{A}))_{\geq 0}$, where $\mathcal{N}_{dg}(\text{Ch}(\mathcal{A}))_{\geq 0}$ is as in Definition 1.3.5.16. Then the pair $(\mathcal{D}^{\text{inj}}(\mathcal{A}) \geq 0, \mathcal{D}^+(\mathcal{A}))$ determines a t-structure on $\mathcal{D}^{\text{inj}}(\mathcal{A})$.

**Proof.** Assertion (1) is a special case of Proposition 1.3.2.10, assertion (2) follows from Proposition 1.3.5.6, and assertion (3) follows from Proposition 1.3.5.18.

**Remark 1.3.6.3.** Let $\mathcal{A}$ be a Grothendieck abelian category, and regard $\mathcal{D}(\mathcal{A})$ and $\mathcal{D}^{\text{inj}}(\mathcal{A})$ as endowed with the t-structures described in Propositions 1.3.5.21 and 1.3.6.2, respectively. Then the inclusion $\mathcal{D}(\mathcal{A}) \hookrightarrow \mathcal{D}^{\text{inj}}(\mathcal{A})$ is t-exact, and induces an isomorphism $\mathcal{D}(\mathcal{A})_{\leq 0} \simeq \mathcal{D}^{\text{inj}}(\mathcal{A})_{\leq 0} = \mathcal{D}^-(\mathcal{A})$. In particular, the heart of $\mathcal{D}^{\text{inj}}(\mathcal{A})$ is equivalent to (the nerve of) the abelian category $\mathcal{A}$ (see Remark 1.3.5.23).

**Remark 1.3.6.4.** Let $\mathcal{A}$ be a Grothendieck abelian category. Proposition 1.3.5.13 implies that the inclusion functor $\mathcal{D}(\mathcal{A}) \hookrightarrow \mathcal{D}^{\text{inj}}(\mathcal{A})$ admits a left adjoint $L$. If $f : Q_\bullet \to Q'_\bullet$ is a morphism in $\mathcal{D}^{\text{inj}}(\mathcal{A})$, then $Lf$ is an equivalence if and only if $f$ is a quasi-isomorphism of chain complexes. In particular, we have $LQ_\bullet \simeq 0$ in the $\infty$-category $\mathcal{D}(\mathcal{A})$ if and only if the chain complex $Q_\bullet$ is acyclic. The collection of chain complexes $Q_\bullet$ satisfying this condition span the full subcategory $\bigcap_n \mathcal{D}^{\text{inj}}(\mathcal{A}) \geq n$. We can summarize the situation as follows: the stable $\infty$-category $\mathcal{D}(\mathcal{A})$ is obtained from the larger stable $\infty$-category $\mathcal{D}^{\text{inj}}(\mathcal{A})$ by dividing out by the stable subcategory $\bigcap_n \mathcal{D}^{\text{inj}}(\mathcal{A}) \geq n \subseteq \mathcal{D}(\mathcal{A})$.

We now review some finiteness conditions on an abelian category $\mathcal{A}$ which guarantee the good behavior of the stable $\infty$-category $\mathcal{D}^{\text{inj}}(\mathcal{A})$.

**Definition 1.3.6.5.** Let $\mathcal{A}$ be an abelian category containing an object $M$. We say that $M$ is Noetherian if every nonempty collection of subobjects of $M$ contains a maximal element. We say that an abelian category $\mathcal{A}$ is locally Noetherian if it is a Grothendieck abelian category and every object $M \in \mathcal{A}$ can be written as a filtered colimit of Noetherian subobjects of $M$. 

Remark 1.3.6.6. Let \( \mathcal{A} \) be an abelian category. Then an object \( M \in \mathcal{A} \) is Noetherian if and only if it satisfies the following condition: for every ascending chain of subobjects
\[
M_0 \hookrightarrow M_1 \hookrightarrow \cdots \hookrightarrow M,
\]
we have \( M_n \simeq M_{n+1} \) for \( n \gg 0 \).

We can now state the main result of this section:

**Theorem 1.3.6.7** (Krause). Let \( \mathcal{A} \) be a locally Noetherian abelian category. Then the \( \infty \)-category \( \mathcal{D}^{\text{inj}}(\mathcal{A}) \) is compactly generated. Moreover, an object \( Q_* \in \mathcal{D}^{\text{inj}}(\mathcal{A}) \) is compact if and only if it satisfies the following conditions:

(a) The object \( Q_* \) lies in the essential image of the inclusion \( \mathcal{D}^+(\mathcal{A}) \hookrightarrow \mathcal{D}^{\text{inj}}(\mathcal{A}) \); in particular, \( H_n(Q_*) \simeq 0 \) for \( n \gg 0 \).

(b) The homology objects \( H_n(Q_*) \) vanish for \( n \ll 0 \).

(c) For every integer \( n \), \( H_n(Q_*) \) is a Noetherian object of the abelian category \( \mathcal{A} \).

**Corollary 1.3.6.8.** Let \( \mathcal{A} \) be a locally Noetherian abelian category. Then the \( \infty \)-category \( \mathcal{D}^{\text{inj}}(\mathcal{A}) \) is presentable.

The proof of Theorem 1.3.6.7 will be given at the end of this section. Let us begin by reviewing the theory of locally Noetherian abelian categories.

**Proposition 1.3.6.9.** Let \( \mathcal{A} \) be an abelian category, and let \( \mathcal{A}_0 \subseteq \mathcal{A} \) be the full subcategory spanned by the Noetherian objects. Then:

1. The subcategory \( \mathcal{A}_0 \subseteq \mathcal{A} \) is closed under the formation of subobjects, quotient objects, and extensions. In particular, \( \mathcal{A}_0 \) is an abelian category, and the inclusion \( \mathcal{A}_0 \hookrightarrow \mathcal{A} \) is injective.

2. If the abelian category \( \mathcal{A} \) is locally Noetherian, then \( \mathcal{A}_0 \) is essentially small, and the inclusion \( \mathcal{A}_0 \hookrightarrow \mathcal{A} \) induces an equivalence of categories \( \text{Ind}(\mathcal{A}_0) \simeq \mathcal{A} \).

**Proof.** We first note that if \( N \in \mathcal{A} \) is a subobject or quotient of an object \( M \in \mathcal{A} \), then the partially ordered set of isomorphism classes of subobjects of \( N \) can be regarded as a subset of the partially ordered set of isomorphism classes of subobjects of \( M \). It follows immediately that if \( M \) is Noetherian, then \( N \) is Noetherian. To complete the proof of (1), suppose that we are given an exact sequence
\[
0 \to M' \to M \to M'' \to 0
\]
where \( M' \) and \( M'' \) are Noetherian; we wish to prove that \( M \) is Noetherian. Suppose we are given a nonempty collection \( \{M_\alpha\}_{\alpha \in A} \) of subobjects of \( M \). Since \( M'' \) is Noetherian, the collection of subobjects \( \{\text{im}(M_\alpha \to M'')\}_{\alpha \in A} \) contains a maximal element \( N \). Let \( B = \{\alpha \in A : \text{im}(M_\alpha \to M'') \simeq N\} \). Since \( M' \) is Noetherian, the collection \( \{M_\beta \times_M M'\}_{\beta \in B} \) of subobjects of \( M' \) contains a maximal element \( M_\beta \times_M M' \).

It is now easy to see that \( M_\beta \) is a maximal element of the collection of subobjects \( \{M_\alpha\}_{\alpha \in A} \).

We now prove (2). Assume that \( \mathcal{A} \) is locally Noetherian. Fix a small collection of objects \( \{M_i\}_{i \in I} \) which generates \( \mathcal{A} \) under colimits. Then, for every object \( M \in \mathcal{A} \), there exists an epimorphism \( \prod N_\alpha \to M \), where each \( N_\alpha \) belongs to the set \( \{M_i\}_{i \in I} \). It follows that the canonical map
\[
\prod_{i \in I, f : M_i \to M} M_i \to M
\]
is an epimorphism. In particular, every subobject \( M' \) of \( M \) can be identified with the image of the map \( \prod_{i \in I, f : M_i \to M'} M_i \to M \). It follows that \( M' \) is determined (up to canonical isomorphism) by the images of
the injective group homomorphisms \( \{ \text{Hom}_A(M_i, M') \to \text{Hom}_A(M_i, M) \}_{i \in I} \). In particular, there exists a set of representatives for the collection of all isomorphism classes of subobjects of \( M \).

We now prove that \( A_0 \) is locally small. Let \( M \in A \) be Noetherian, and choose an epimorphism \( \prod_{\alpha \in J} N_\alpha \to M \) where each \( N_\alpha \) belongs to \( \{ M_i \}_{i \in I} \). For every finite subset \( J' \subseteq J \), let \( M_{J'} \) denote the image of the composite map

\[
\prod_{\alpha \in J'} N_\alpha \to \prod_{\alpha \in J} N_\alpha \to M.
\]

Since \( A \) is a Grothendieck abelian category, the formation of images in \( A \) commutes with filtered colimits, so that \( M \) is given by the filtered colimit \( \lim_{J' \subseteq J} M_{J'} \). Since \( M \) is Noetherian, the collection of subobjects \( \{ M_{J'} \} \) contains a maximal element. It follows that there exists a finite subset \( J' \subseteq J \) such that \( M_{J'} \cong M \).

Replacing \( J \) by \( J' \), we may assume that \( J \) is finite. Then \( M \cong \text{coker}(K \to \prod_{\alpha \in J} N_\alpha) \), for some subobject \( K \) of \( \prod_{\alpha \in J} N_\alpha \). Since there are only a bounded number of choices for the isomorphism type of the coproduct \( \prod_{\alpha \in J} N_\alpha \) and a bounded number of choices for the subobject \( J \), we conclude that there are only a bounded number of possibilities for the isomorphism class of \( M \): that is, the category \( A_0 \) is essentially small.

We next claim that if \( M \in A \) is Noetherian, then \( M \) is a compact object of \( A \). To prove this, suppose we are given a diagram \( \{ N_\alpha \}_{\alpha \in A} \) indexed by a filtered partially ordered set \( A \), having colimit \( N \in A \). We wish to prove that the canonical map

\[
\theta : \lim_{\alpha} \text{Hom}_A(M, N_\alpha) \to \text{Hom}_A(M, N)
\]

is bijective. We first show that \( \theta \) is injective. Suppose we are given a map \( \phi : M \to N_\alpha \) such that the composite map \( \phi' : M \overset{\phi}{\to} N_\alpha \to N \) vanishes. For each \( \beta \geq \alpha \), let \( \phi_\beta \) denote the composite map \( M \overset{\phi}{\to} N_\alpha \to N_\beta \). Since \( A \) is a Grothendieck abelian category, we have \( M \cong \text{coker}(\phi') \cong \lim \ker(\phi_\beta) \). Since \( M \) is Noetherian, we conclude that \( M \cong M_\beta \) for some \( \beta \geq \alpha \): that is, the map \( \phi_\beta \) is zero. This completes the proof that \( \theta \) is injective.

We now verify the surjectivity of \( \theta \). Fix a morphism \( \phi : M \to N \). For each index \( \alpha \in A \), let \( \widetilde{M}_\alpha = M \times_N N_\alpha \). Then \( M \) can be identified with the filtered colimit \( \lim_{\alpha} \text{im}(\widetilde{M}_\alpha \to M) \). Since \( M \) is Noetherian, there exists an index \( \alpha \in A \) such that the map \( \widetilde{M}_\alpha \to M \) is an epimorphism. Write \( \widetilde{M}_\alpha \) as a filtered colimit of Noetherian subobjects \( \widetilde{M}_{\alpha, \gamma} \). Then \( M \cong \lim_{\alpha, \gamma} \text{im}(\widetilde{M}_{\alpha, \gamma} \to M) \). Since \( M \) is Noetherian, we can choose \( \gamma \) such that \( \widetilde{M}_{\alpha, \gamma} \to M \) is an epimorphism. Set \( \overline{M} = \widetilde{M}_{\alpha, \gamma} \), and let \( K \) denote the kernel of the epimorphism \( \overline{M} \to M \). Then the composite map

\[
\overline{M} \hookrightarrow \widetilde{M}_\alpha \to N_\alpha \to N
\]

annihilates \( K \). For each \( \beta \geq \alpha \), let \( K_\beta \) denote the kernel of the composite map

\[
K \hookrightarrow \widetilde{M}_\alpha \to N_\alpha \to N.
\]

Then \( K \cong \lim_{\alpha \leq \beta} K_\beta \). Since \( K \) is a subobject of \( \overline{M} \), it is Noetherian. We therefore have \( K \cong K_\beta \) for some \( \beta \geq \alpha \). It follows that the map \( \overline{M} \to N_\alpha \to N_\beta \) factors through \( \overline{M}/K \cong M \), so that \( \phi \) lies in the image of \( \text{Hom}_A(M, N_\beta) \).

Applying Proposition T.5.3.5.11, we deduce that the inclusion \( A_0 \hookrightarrow A \) extend to a fully faithful embedding \( F : \text{Ind}(A_0) \to A \). Since \( A \) is locally Noetherian, it is generated by \( A_0 \) under filtered colimits; it follows immediately that \( F \) is an equivalence of categories.

**Remark 1.3.6.10.** Proposition 1.3.6.9 has a converse. Suppose that \( A_0 \) is a small abelian category in which every object is Noetherian. Then \( \text{Ind}(A_0) \) is a locally Noetherian abelian category, and an object of \( \text{Ind}(A_0) \) is Noetherian if and only if it belongs to the essential image of the fully faithful embedding \( j : A_0 \to \text{Ind}(A_0) \).

To prove this, we first note that \( \text{Ind}(A_0) \) compactly generated. It follows that filtered colimits in \( \text{Ind}(A_0) \) are left exact and therefore \( \text{Ind}(A_0) \) is a Grothendieck abelian category. We next claim that if \( M \in \text{Ind}(A_0) \) belongs to the essential image of \( j \), then every subobject of \( M \) belongs to the essential image of \( j \). To prove
1.3. HOMOLOGICAL ALGEBRA AND DERIVED CATEGORIES

this, write $M = j(N)$ for some $N \in A_0$. Let $M'$ be a subobject of $M$, and write $M' \simeq \lim_{\alpha \in A} j(N_{\alpha})$ where the colimit is taken over some filtered partially ordered set $A$. Then $M' \simeq \lim_{\alpha \in A} j(\text{im}(N_{\alpha} \to N))$. Since $N$ is Noetherian, we deduce that there exists $\alpha \in A$ such that $M' \simeq \text{im}(N_{\alpha} \to N)$, so that $M'$ belongs to the image of $j$.

The above argument shows that for each object $N \in A_0$, the partially ordered set of isomorphism classes of subobjects of $N$ is isomorphic to the partially ordered set of isomorphism classes of subobjects of $j(N)$. Since $N \in A_0$ is Noetherian, we conclude that $j(N) \in \text{Ind}(A_0)$ is Noetherian. Now suppose that $M \simeq \lim_{\alpha \in A} j(N_{\alpha})$ is an arbitrary object of $\text{Ind}(A_0)$. Then $M$ is equivalent to the filtered colimit of subobjects $\lim_{\alpha \in A} \text{im}(j(N_{\alpha}) \to M)$. Each of these subobjects is a quotient of $j(N_{\alpha})$, and therefore Noetherian. This proves that the abelian category $\text{Ind}(A_0)$ is locally Noetherian. If the object $M$ above is Noetherian, then there exists an index $\alpha \in A$ such that $M \simeq \text{im}(j(N_{\alpha}) \to M)$. Then $M$ is a quotient of $j(N_{\alpha})$. Since $\ker(j(N_{\alpha}) \to M)$ is a subobject of $j(N_{\alpha})$, it belongs to the essential image of $j$. It follows that every Noetherian object $M \in \text{Ind}(A_0)$ belongs to the essential image of $j$.

Proposition 1.3.6.9 implies that a locally Noetherian abelian category $A$ is “controlled” by the full subcategory $A_0 \subseteq A$ spanned by the Noetherian objects. In particular, we have the following characterization of injective objects of $A$:

**Proposition 1.3.6.11.** Let $A$ be a locally Noetherian abelian category, and let $Q \in A$ be an object. The following conditions are equivalent:

1. The object $Q \in A$ is injective.
2. For every Noetherian object $M \in A$ and every subobject $M'$ of $M$, the restriction map $\text{Hom}_A(M, Q) \to \text{Hom}_A(M', Q)$ is surjective.

**Proof.** The implication (1) $\Rightarrow$ (2) is obvious. Conversely, suppose that (2) is satisfied; we wish to show that $Q$ is injective. Let $i_0 : M_0 \to M$ be a monomorphism in $A$ and suppose we are given a map $f_0 : M_0 \to Q$; we wish to show that $f_0$ factors through $i_0$. Let $P$ be set of all isomorphism classes of pairs $(i_1 : M_1 \to M, f_1)$, where $i_1$ is a monomorphism, the map $i_0$ factors (automatically uniquely) as a composition $M_0 \xrightarrow{i_0} M_1 \xrightarrow{i_1} M$, and $f_1 : M_1 \to Q$ is a map satisfying $f_0 \circ j = f_0$. Using Zorn’s Lemma, we deduce that $P$ has a maximal element $(i_1 : M_1 \to M, f_1)$. We will complete the proof by showing that $i_1$ is an isomorphism. Since $A$ is locally Noetherian, $M_1$ can be written as a filtered colimit of Noetherian subobjects. It will therefore suffice to show that $M_1$ contains every Noetherian subobject $N$ of $M$. Assume otherwise, and let $N' = M_1 \times_M N$. Then $N' = M_1 \coprod_{N'} N$ is a subobject of $M$ properly containing $M_1$. By maximality, the map $f_1 : M_1 \to Q$ cannot be extended to a map $f_2 : M_2 \to Q$. It follows that the restriction of $f_1$ to $N'$ cannot be extended to a map from $N$ into $Q$, contradicting assumption (2).

**Corollary 1.3.6.12.** Let $A$ be a locally Noetherian abelian category. Then the collection of injective objects of $A$ is closed under filtered colimits.

**Corollary 1.3.6.13.** Let $A$ be a locally Noetherian abelian category. Then the collection of injective objects of $A$ is closed under (possibly infinite) sums.

**Proof.** It is clear that the collection of injective objects is closed under finite sums, and an arbitrary sum can be written as a filtered colimit of finite sums.

**Corollary 1.3.6.14.** Let $A$ be a locally Noetherian abelian category, and suppose we are given a collection of objects $\{Q(\alpha)_* \in \text{Ch}(\text{Ind}(A))\}_{\alpha \in A}$. Then:

1. The coproduct $Q_* \simeq \coprod_{\alpha \in A} Q(\alpha)_*$ is a chain complex of injective objects of $A$.
2. The canonical maps $Q(\alpha)_* \to Q_*$ exhibit $Q_*$ as a coproduct of the objects $Q(\alpha)_*$ in the $\infty$-category $\text{D}^{(\text{b})}(A)$.
Let \( \mathcal{A} \) be a locally Noetherian abelian category. Then the \( \infty \)-category \( \mathcal{D}^{\text{inj}}(\mathcal{A}) \) admits small colimits.

**Proof.** Combine Corollary 1.3.6.14 with Proposition 1.4.4.1.

We now turn to the problem of computing mapping spaces in \( \mathcal{D}^{\text{inj}}(\mathcal{A}) \).

**Proposition 1.3.6.16.** Let \( \mathcal{A} \) be a Grothendieck abelian category, let \( i : M'_* \to M_* \) be a quasi-isomorphism in \( \text{Ch}_{\leq 0}(\mathcal{A}) \), and let \( Q_* \) be a complex of injective objects of \( \mathcal{A} \). Then composition with \( i \) induces a quasi-isomorphism of chain complexes

\[
\text{Map}_{\text{Ch}(\mathcal{A})}(M_*, Q_*) \to \text{Map}_{\text{Ch}(\mathcal{A})}(M'_*, Q_*).
\]

**Proof.** Since \( Q_* \) is degreewise injective, we have a short exact sequence of chain complexes

\[
0 \to \text{Map}_{\text{Ch}(\mathcal{A})}(M_*/M'_*, Q_*) \to \text{Map}_{\text{Ch}(\mathcal{A})}(M_*, Q_*) \to \text{Map}_{\text{Ch}(\mathcal{A})}(M'_*, Q_*) \to 0.
\]

It will therefore suffice to show that the chain complex of abelian groups \( \text{Map}_{\text{Ch}(\mathcal{A})}(M_*/M'_*, Q_*) \) is acyclic. In other words, we must show that for every integer \( n \), every chain map \( M_*/M'_* \to Q_*[n] \) is nullhomotopic. To prove this, we are free to replace \( Q_* \) by the chain complex

\[
\cdots \to 0 \to Q_{1-n} \to Q_{-n} \to \cdots
\]

In this case, \( Q_* \) is fibrant with respect to the model structure of Proposition 1.3.5.3 (see Proposition 1.3.5.6), so the desired result follows from Proposition 1.3.5.11 (since the quotient \( M_*/M'_* \) is acyclic).

**Example 1.3.6.17.** Let \( \mathcal{A} \) be a locally Noetherian abelian category. The identification of \( \mathcal{A} \) with the heart of \( \mathcal{D}^{\text{inj}}(\mathcal{A}) \) determines a functor \( f : \text{N}(\mathcal{A}) \to \mathcal{D}^{\text{inj}}(\mathcal{A}) \). Unwinding the definitions, we see that this functor carries an object \( M \in \mathcal{A} \) to a chain complex

\[
\cdots \to 0 \to Q_0 \to Q_{-1} \to \cdots
\]

which is an injective resolution of \( M \). Using Proposition 1.3.6.16, we conclude that for every complex \( Q'_* \in \mathcal{D}^{\text{inj}}(\mathcal{A}) \), we can identify the mapping space \( \text{Map}_{\mathcal{D}^{\text{inj}}(\mathcal{A})}(f(M), Q'_*) \) with the simplicial set obtained by applying the Dold-Kan correspondence to the truncation of the chain complex

\[
\cdots \to \text{Hom}_\mathcal{A}(M, Q'_1) \to \text{Hom}_\mathcal{A}(M, Q'_0) \to \text{Hom}_\mathcal{A}(M, Q'_{-1}) \to \cdots
\]

In particular, we have canonical isomorphisms

\[
\text{Ext}_{\mathcal{D}^{\text{inj}}(\mathcal{A})}^n(f(M), Q'_*) \simeq \text{H}_{-n}(\text{Hom}_\mathcal{A}(M, Q'_*)).
\]

**Corollary 1.3.6.18.** Let \( \mathcal{A} \) be a locally Noetherian abelian category. Then every Noetherian object of the heart \( \mathcal{D}^{\text{inj}}(\mathcal{A}) \) is compact when viewed as an object of \( \mathcal{D}^{\text{inj}}(\mathcal{A}) \).

**Proof.** Let \( f : \text{N}(\mathcal{A}) \to \mathcal{D}^{\text{inj}}(\mathcal{A}) \) be as in Example 1.3.6.17, and let \( M \) be a Noetherian object of \( \mathcal{A} \). We wish to show that \( f(M) \in \mathcal{D}^{\text{inj}}(\mathcal{A}) \) is compact. Using Proposition 1.4.4.1, we are reduced to proving that for every collection of objects \( Q(\alpha)_* \in \mathcal{D}^{\text{inj}}(\mathcal{A}) \) having coproduct \( Q_* \), the canonical map

\[
\bigoplus_\alpha \text{Ext}_{\mathcal{D}^{\text{inj}}(\mathcal{A})}^0(f(M), Q(\alpha)_*) \to \text{Ext}_{\mathcal{D}^{\text{inj}}(\mathcal{A})}^0(f(M), Q_*)
\]

is an isomorphism. Using Corollary 1.3.6.13, we can take \( Q_* \) to be the direct sum of the chain complexes \( Q(\alpha)_* \) in the ordinary category \( \text{Ch}(\mathcal{A}) \). In this case, the desired result follows immediately from the description of the relevant Ext-groups supplied by Example 1.3.6.17.
Proposition 1.3.6.19. Let $\mathcal{A}$ be a locally Noetherian abelian category, and let $f : N(\mathcal{A}) \to D^{\text{inj}}(\mathcal{A})$ be the functor determined by the identification of $\mathcal{A}$ with the heart of $D^{\text{inj}}(\mathcal{A})$. Then $f$ preserves filtered colimits.

Proof. Let $\mathcal{A}_0$ denote the full subcategory of $\mathcal{A}$ spanned by the Noetherian objects, and let $f_0$ be the restriction of $f$ to $N(\mathcal{A}_0)$. Let $f' : N(\mathcal{A}) \to D^{\text{inj}}(\mathcal{A})$ be a left Kan extension of $f_0$, so that $f'$ commutes with filtered colimits (Lemma T.5.3.5.8). The identity map from $f'_0|N(\mathcal{A}_0)$ to $f|N(\mathcal{A}_0)$ extends to a natural transformation of functors $\phi : f' \to f$. We will complete the proof by showing that $\gamma$ is an equivalence.

Let $M$ be an object of $\mathcal{A}$; we wish to show that $\phi$ induces an equivalence $f'(M) \to f(M)$ in the $\infty$-category $D^{\text{inj}}(\mathcal{A})$. We define a transfinite sequence $\{M_\alpha\}$ of subobjects of $M$ as follows:

- Let $M_0 = 0$.
- If $\lambda$ is a limit ordinal, set $M_\lambda = \varinjlim_{\alpha < \lambda} M_\alpha$.
- Suppose that $M_\alpha$ is defined and not isomorphic to $M$. Since $\mathcal{A}$ is locally Noetherian, there exists a nonzero Noetherian subobject $N$ of the quotient $M/M_\alpha$. Let $M_{\alpha+1}$ be the inverse image of $N$ in $M$.

Since the collection of all isomorphism classes of subobjects of $M$ is bounded in size (see the proof of Proposition 1.3.6.9), this construction must eventually stop: that is, there exists an ordinal $\alpha$ such that $M_\alpha \cong M$. For each $\beta \leq \alpha$, let $\phi_\beta$ be the morphism from $f'(M_\beta)$ to $f(M_\beta)$ determined by $\phi$. We will prove that each of the maps $\phi_\beta$ is an equivalence. When $\beta = 0$, this is clear (since $M_0 \cong 0$ is a Noetherian object of $\mathcal{A}$). We now proceed by induction on $\beta$. There are two cases to consider:

- Suppose that $\beta < \alpha$ and that $\phi_\beta$ is an equivalence. We will show that $\phi_{\beta+1}$ is an equivalence. By construction, $M_{\beta+1}$ is the inverse image of a Noetherian subobject $N \subseteq M/M_\beta$. Since $\mathcal{A}$ is locally Noetherian, there exists a Noetherian subobject $N$ of $M_{\beta+1}$ such that the composite map

$$N \hookrightarrow M_{\beta+1} \to N$$

is an epimorphism. Let $N_0$ denote the fiber product $N \times_{M_{\beta+1}} M_\beta$. We then have a pushout diagram $\sigma$:

$$\begin{array}{ccc}
N_0 & \rightarrow & N \\
\downarrow & & \downarrow \\
M_\beta & \rightarrow & M_{\beta+1}
\end{array}$$

in the abelian category $\mathcal{A}$, where the horizontal maps are monomorphisms. It follows that $f(\sigma)$ is a pushout diagram in $D^{\text{inj}}(\mathcal{A})$. Since $N_0$ and $N$ are Noetherian, the natural transformation $\phi$ induces equivalences

$$f'(N) \to f(N) \quad f'(N_0) \to f(N_0).$$

Consequently, to prove that $\phi_{\beta+1}$ is an equivalence, it will suffice to show that the diagram $f'(\sigma)$ is a pushout diagram in $D^{\text{inj}}(\mathcal{A})$. Since $\mathcal{A}$ is locally Noetherian, we can write $M_\beta$ as a filtered colimit of Noetherian subobjects $M_{\beta,i}$ which contain $N_0$. For every such index $i$, form a pushout diagram

$$\begin{array}{ccc}
N_0 & \rightarrow & N \\
\downarrow & & \downarrow \\
M_{\beta,i} & \rightarrow & P_i
\end{array}$$

in the abelian category $\mathcal{A}$. Then $\sigma \cong \varprojlim_{\beta} \sigma_i$. Since the functor $f'$ preserves filtered colimits, we have $f'(\sigma) \cong \varprojlim_{\beta} f'(\sigma_i)$. It will therefore suffice to show that each of the diagrams $f'(\sigma_i)$ is a pushout square in $D^{\text{inj}}(\mathcal{A})$. This is clear, since $\sigma_i$ is a diagram of Noetherian objects of $\mathcal{A}$ so that $\phi$ induces an equivalence $f'(\sigma_i) \to f(\sigma_i)$. 

• Suppose that $\lambda \leq \alpha$ is a limit ordinal, and that $\phi_\beta$ is an equivalence for all ordinals $\beta < \lambda$. We wish to show that $\phi_\lambda$ is an equivalence. For this, it suffices to show that $\phi_\lambda \simeq \lim_{\beta < \lambda} \phi_\beta$. Because the functor $f'$ preserves filtered colimits, we are reduced to proving that $f(M_\lambda)$ is a filtered colimit of the diagram $\{ f(M_\beta) \}_{\beta < \lambda}$. For each object $\lambda \in \Lambda$, let $\tau_*(\lambda) \in \text{Ch}(\Lambda_{ inj})$ denote a (functorial) choice of injective resolution of $\lambda$. Using Corollary 1.3.6.18, we are reduced to proving that $\tau_*(\lambda)$ is fibrant. Using the criterion given in Corollary T.A.2.9.24, we are reduced to proving that for $\beta < \lambda$, the map

$$
\theta' : \text{DK}(\tau_{\geq 0} \text{Hom}_\Lambda(M_\lambda, Q'_\lambda)) \to \lim_{\gamma < \beta} \text{DK}(\tau_{\geq 0} \text{Hom}_\Lambda(M_\gamma, Q'_\gamma))
$$

is a Kan fibration. This is obvious if $\beta$ is a limit ordinal (in this case, $\theta'$ is an isomorphism). If $\beta = \gamma + 1$ is a successor ordinal, the desired result follows from Proposition 1.3.2.11.

We are now ready to prove our main result:

**Proof of Theorem 1.3.6.7.** Let $\mathcal{C}$ denote the full subcategory of $\mathcal{D}^\text{ini}(\Lambda)$ spanned by those objects which satisfy conditions (1), (2), and (3). It follows from Corollary 1.3.6.18 that $\mathcal{C}$ consists of compact objects of $\mathcal{D}^\text{ini}(\Lambda)$. Using Proposition T.5.3.5.11, we see that the inclusion $f : \mathcal{C} \hookrightarrow \mathcal{D}^\text{ini}(\Lambda)$ extends to a fully faithful embedding $F : \text{Ind}(\mathcal{C}) \to \mathcal{D}^\text{ini}(\Lambda)$ which preserves filtered colimits. Since $f$ is exact, the functor $F$ preserves small colimits. We will complete the proof by showing that $F$ is essentially surjective (since $\mathcal{C}$ is idempotent complete, this will imply that $F$ induces an equivalence from $\mathcal{C}$ to the full subcategory of $\mathcal{D}^\text{ini}(\Lambda)$ spanned by the compact objects).

Let $\overline{\mathcal{C}}$ denote the essential image of the functor $F$ (equivalently, $\overline{\mathcal{C}}$ can be described as the full subcategory of $\mathcal{D}^\text{ini}(\Lambda)$ generated by $\mathcal{C}$ under small colimits). We wish to show that every chain complex $Q_*$ of injective objects of $\Lambda$ belongs to $\overline{\mathcal{C}}$. Let $\text{Ch}(\Lambda_{ inj})_\Delta$ denote the underlying simplicial category of the differential graded category $\text{Ch}(\Lambda_{ inj})$. Note that $Q_*$ can be identified with the homotopy colimit of the diagram of chain complexes $Q_\tau\leftarrow 0 \rightarrow Q_{n-2} \rightarrow Q_n \to 0 \rightarrow \cdots$.

It will therefore suffice to show that every such chain complex belongs to $\overline{\mathcal{C}}$; that is, we may suppose that $Q_* \in \mathcal{D}^+(\Lambda)$.

Replacing $Q_*$ by a shift, we may suppose that $Q_* \in \mathcal{D}^+(\Lambda)$, and that the t-structure on $\mathcal{D}^+(\Lambda)$ is right complete, $Q_*$ is given by the colimit of the sequence $\tau_{\geq -m} Q_*$. It will therefore suffice to show that each truncation $\tau_{\geq -m} Q_*$ belongs to $\overline{\mathcal{C}}$. We proceed by induction on $m$, the case $m = 0$ being trivial. We have a fiber sequence

$$
\tau_{\geq -m} Q_* \to \tau_{\geq -m} Q_* \to M[-m],
$$

where $M$ is an object belonging to the heart of $\mathcal{D}^-(\Lambda)$ (which we can identify with an object of $\Lambda$). Using the inductive hypothesis, we are reduced to proving that $M \in \overline{\mathcal{C}}$. For this, it suffices to show that $\overline{\mathcal{C}}$ contains the heart of $\mathcal{D}^\text{ini}(\Lambda)$, which follows immediately from Proposition 1.3.6.19.

We conclude this section with an additional remark about the t-structure on $\mathcal{D}^\text{ini}(\Lambda)$.
Proposition 1.3.6.20. Let \( A \) be a locally Noetherian abelian category. Then the \( t \)-structure on \( \mathcal{D}^{\text{inj}}(A) \) is accessible (see Definition 1.4.4.12) and compatible with filtered colimits (that is, the full subcategory \( \mathcal{D}^{\text{inj}}_{\leq 0}(A) \subseteq \mathcal{D}^{\text{inj}}(A) \) is closed under filtered colimits).

Proof. To prove that the \( t \)-structure on \( \mathcal{D}^{\text{inj}}(A) \) is accessible, it will suffice to show that the full subcategory \( \mathcal{D}^{\text{inj}}_{\leq 0}(A) \) is presentable. This follows from Proposition 1.3.5.21, since the inclusion \( \mathcal{D}(A) \to \mathcal{D}^{\text{inj}}(A) \) induces an equivalence \( \mathcal{D}(A)_{\leq 0} \simeq \mathcal{D}^{\text{inj}}_{\leq 0}(A) \).

We now show that the full subcategory \( \mathcal{D}^{\text{inj}}_{\leq 0}(A) \subseteq \mathcal{D}^{\text{inj}}(A) \) is closed under filtered colimits. Applying Corollary 1.3.6.13, we deduce that \( \mathcal{D}^{\text{inj}}_{\leq 0}(A) \) is closed under (possibly infinite) coproducts in \( \mathcal{D}^{\text{inj}}(A) \). Suppose next that we are given a sequence

\[
Q(0)_* \to Q(1)_* \to Q(2)_* \to \cdots
\]

of objects of \( \mathcal{D}^{\text{inj}}_{\leq 0}(A) \), having a colimit \( Q_* \) in \( \mathcal{D}^{\text{inj}}(A) \). Then \( Q_* \) can be identified with the cofiber of a map \( \prod Q(n)_* \to \prod Q(n)_* \), and therefore belongs to \( \mathcal{D}^{\text{inj}}_{\leq 0}(A) \). In particular, \( Q_* \) is a colimit of the sequence \( \{Q(n)_*\} \) in the full subcategory \( \mathcal{D}(A) \subseteq \mathcal{D}^{\text{inj}}(A) \), so that \( Q_* \in \mathcal{D}^{\text{inj}}_{\leq 0}(A) \) by virtue of Proposition 1.3.5.21.

Now let \( Q_* \) be an arbitrary object of \( \mathcal{D}^{\text{inj}}_{\leq 0}(A) \). The above argument shows that \( \lim_{\to \gamma \alpha} \tau_{\geq -n} Q_* \) belongs to \( \mathcal{D}^{\text{inj}}_{\leq 0}(A) \). Since the \( t \)-structure on \( \mathcal{D}^+ \) (\( A \)) is right complete, we deduce that \( Q_* \) is a colimit of the sequence \( \{\tau_{\geq -n} Q_*\} \) in the \( \infty \)-category \( \mathcal{D}^+ \) (\( A \)), and therefore also in the larger \( \infty \)-category \( \mathcal{D}^{\text{inj}}(A) \).

Now suppose we are given a filtered diagram \( \{Q(\alpha)_*\} \) of objects of \( \mathcal{D}^{\text{inj}}_{\leq 0}(A) \). We wish to show that \( \lim_{\to \gamma \alpha} Q(\alpha)_* \) belongs to \( \mathcal{D}^{\text{inj}}_{\leq 0}(A) \). We have

\[
\lim_{\to \gamma \alpha} Q(\alpha)_* \simeq \lim_{\to \gamma \alpha} \tau_{\geq -n} Q(\alpha)_* \simeq \lim_{\to \gamma \alpha} \tau_{\geq -n} Q(\alpha)_*.
\]

It will therefore suffice to show that each of the colimits \( \lim_{\to \gamma \alpha} \tau_{\geq -n} Q(\alpha)_* \) belongs to \( \mathcal{D}^{\text{inj}}_{\leq 0} \). We proceed by induction on \( n \), the case \( n = 0 \) being trivial. To carry out the inductive step, we observe that there is a cofiber sequence

\[
\lim_{\to \gamma \alpha} \tau_{\geq 1-n} Q(\alpha)_* \to \lim_{\to \gamma \alpha} \tau_{\geq -n} Q(\alpha)_* \to (\lim_{\to \gamma \alpha} \pi_{-n} Q(\alpha)_*)[-n].
\]

Using the inductive hypothesis, we are reduced to proving that \( \lim_{\to \gamma \alpha} \pi_{-n} Q(\alpha)_* \) belongs to \( \mathcal{D}^{\text{inj}}_{\leq n} Q(\alpha)_* \). In fact, Proposition 1.3.6.19 gives the stronger statement \( \lim_{\to \gamma \alpha} \pi_{-n} Q(\alpha)_* \in \mathcal{D}^{\text{inj}}_{\leq 0} \).

1.4 Spectra and Stabilization

One very broad goal of homotopy theory is to classify continuous maps between topological spaces up to homotopy. To formulate the problem more precisely, let \( X \) and \( Y \) be topological spaces equipped with base points, let \( \text{Map}_*(X,Y) \) denote the space of continuous pointed maps from \( X \) to \( Y \), and let \([X,Y] = \pi_0 \text{Map}_*(X,Y)\) be the set of homotopy classes of pointed maps from \( X \) to \( Y \); one would like to describe the set \([X,Y]\). This is difficult in part because the problem is essentially nonlinear: in general, the set \([X,Y]\) does not have any algebraic structure. However, the situation is better in some special cases. For example, if \( X \) is the suspension of another pointed space \( X' \), then \([X,Y] \simeq \pi_1 \text{Map}_*(X',Y)\) admits a group structure. If \( X' \) is itself the suspension of another space \( X'' \), then the group \([X,Y] \simeq \pi_2 \text{Map}_*(X'',Y)\) is abelian. One can attempt to use these observations to study the mapping sets \([X,Y]\) in general: the construction \( X \mapsto \Sigma(X) \) is functorial in \( X \), so we have natural maps

\[
[X,Y] \to [\Sigma(X),\Sigma(Y)] \to [\Sigma^2(X),\Sigma^2(Y)] \to \cdots
\]

In particular, we can view each \([\Sigma^n(X),\Sigma^n(Y)]\) as an approximation to \([X,Y]\); these approximations are often easier to study, since they admit group structures for \( n > 0 \) (and are abelian for \( n > 1 \)). If \( X \) and \( Y \)
CHAPTER 1. STABLE \(\infty\)-CATEGORIES

are finite pointed CW complexes, the direct limit \(\varinjlim_{n}[\Sigma^n(X), \Sigma^n(Y)]\) is an abelian group, called the \textit{group of homotopy classes of stable maps from} \(X\) \textit{to} \(Y\); we will denote this group by \([X,Y]_s\).

The abelian groups \([X,Y]_s\) can be regarded as simplified (or linearized) versions of the homotopy sets \([X,Y]\). To study them systematically, it is useful to linearize the homotopy category \(\mathcal{K}_s\) of (pointed) spaces itself: that is, to work with a version of the homotopy category where the morphisms are given by homotopy classes of stable maps, rather than homotopy classes of maps. The relevant category is often called the \textit{stable homotopy category}, or the \textit{homotopy category of spectra}. It can be described in several different ways:

\((A)\) There is an obvious candidate for a category \(\mathcal{C}_0\) which satisfies the requirement given above: namely, we take the objects of \(\mathcal{C}_0\) to be finite pointed CW complexes, and the morphisms to be given by the formula \(\text{Hom}_{\mathcal{C}_0}(X,Y) = [X,Y]_s\). By construction, we have canonical bijections \([X,Y]_s \simeq [\Sigma(X), \Sigma(Y)]_s\); in other words, the suspension functor \(X \mapsto \Sigma(X)\) determines a fully faithful embedding from \(\mathcal{C}_0\) to itself. For many purposes, it is convenient to work in a slightly larger category \(\mathcal{C}\), on which the suspension functor \(X \mapsto \Sigma(X)\) is an equivalence of categories. One can achieve this end by formally introducing objects of the form \(\Sigma^n(X)\) for all integers \(n\). More precisely, we let \(\mathcal{C}\) be the category whose objects are pairs \((X,n)\), where \(X\) is a pointed finite CW complex and \(n \in \mathbb{Z}\) an integer, with morphisms given by the formula

\[
\text{Hom}_{\mathcal{C}}((X,m),(Y,n)) = \varinjlim_{k \geq 0} [\Sigma^{m+k}(X), \Sigma^{n+k}(Y)].
\]

The construction \(X \mapsto (X,0)\) determines a fully faithful embedding \(\mathcal{C}_0 \hookrightarrow \mathcal{C}\), and the suspension functor \(X \mapsto \Sigma(X)\) on \(\mathcal{C}_0\) extends (up to isomorphism) to an equivalence of \(\mathcal{C}\) with itself, given by the formula \((X,n) \mapsto (X,n+1)\).

We will refer to \(\mathcal{C}\) as the \textit{homotopy category of finite spectra}. Unlike the homotopy category of spaces (or pointed spaces), it possesses a rich algebraic structure: for example, it is a triangulated category. To prove this, it suffices (by Theorem 1.1.2.15) to realize \(\mathcal{C}\) as the homotopy category of a stable \(\infty\)-category. This \(\infty\)-category can be obtained by the same formal procedure used to define \(\mathcal{C}\). Namely, we begin with the \(\infty\)-category \(\text{Sp}_{\text{fin}}\) of finite pointed spaces (Notation 1.4.2.5), and formally invert the suspension functor by passing to the colimit of the sequence

\[
\text{Sp}_{\text{fin}} \xrightarrow{\Sigma} \text{Sp}_{\text{fin}} \xrightarrow{\Sigma} \cdots
\]

We will denote this colimit by \(\text{Sp}_{\text{fin}}\), and refer to it as the \textit{\(\infty\)-category of finite spectra}. We denote the the Ind-completion of \(\text{Sp}_{\text{fin}}\) by \(\text{Sp}\), and refer to it as the \textit{\(\infty\)-category of spectra}. As we will see, \(\text{Sp}\) is a stable \(\infty\)-category, whose homotopy category can be identified with the classical stable homotopy category.

\((B)\) The passage from the \(\infty\)-category \(\text{Sp}_{\text{fin}}\) to its Ind-completion \(\text{Sp}\) is important if we wish to work with an \(\infty\)-category which admits arbitrary limits and colimits. This is clear, since the \(\infty\)-category \(\text{Sp}_{\text{fin}}\) has strong finiteness conditions built into its definition. We can attempt to remove these conditions by beginning not with the \(\infty\)-category \(\text{Sp}_{\text{fin}}\) of finite pointed spaces, but its Ind-completion \(\text{Ind}(\text{Sp}_{\text{fin}}) \simeq \text{Sp}_{\text{fin}}\). A formal argument shows that the Ind-completion of the direct limit

\[
\text{Sp}_{\text{fin}} \xrightarrow{\Sigma} \text{Sp}_{\text{fin}} \xrightarrow{\Sigma} \text{Sp}_{\text{fin}} \xrightarrow{\Sigma} \cdots
\]

is equivalent to the homotopy inverse limit of the tower

\[
\text{Ind}(\text{Sp}_{\text{fin}}) \xrightarrow{\Omega} \text{Ind}(\text{Sp}_{\text{fin}}) \xrightarrow{\Omega} \cdots
\]

where \(\Omega\) denotes the loop space functor (the right adjoint of the suspension \(\Sigma\)). We can therefore describe \(\text{Sp}\) as an \(\infty\)-category of \textit{infinite loop spaces}: that is, infinite sequences of pointed spaces \(\{E(n)\}\) equipped with homotopy equivalences \(E(n) \simeq \Omega E(n+1)\).
1.4. SPECTRA AND STABILIZATION

(C) Another approach to the subject of stable homotopy theory is to study invariants of (pointed) topological spaces which are invariant under suspension. For example, singular cohomology has this property: for every pointed topological space $X$, there are canonical isomorphisms $\tilde{H}^n(X) \simeq \tilde{H}^{n+1}(\Sigma(X))$, where $\tilde{H}$ denotes the functor of reduced (integral) cohomology. More generally, one can consider generalized cohomology theories: that is, sequences of functors $\{h^n\}_{n \in \mathbb{Z}}$ from the homotopy category of pointed spaces to the category of abelian groups, together with natural isomorphisms $\gamma_n : h^nX \simeq h^{n+1}\Sigma(X)$, satisfying a suitable collection of axioms (see Definition 5.5.3.8). The celebrated Brown representability theorem (Theorem 1.4.1.2) guarantees that each of the functors $h^n$ is representable by a pointed space $E(n)$, and the natural isomorphisms $\gamma_n$ give homotopy equivalences $E(n) \simeq \Omega E(n+1)$. In other words, any cohomology theory $\{h^n\}_{n \in \mathbb{Z}}$ can be represented by a spectrum $\{E(n)\}_{n \in \mathbb{Z}}$: we can therefore regard $\text{Sp}$ as an $\infty$-category whose objects are cohomology theories. (This perspective merits a word of caution: every morphism $f : E \to E'$ in $\text{Sp}$ induces a natural transformation between the corresponding cohomology theories, but this latter map can be zero even if $f$ is not nullhomotopic. In other words, passage from a spectrum $E$ to the underlying cohomology theory is not faithful in general.)

(D) Let $\{E(n)\}_{n \in \mathbb{Z}}$ be a spectrum. Then $E(0) \simeq \Omega E(1)$ is a loop space: in particular, it admits a multiplication $E(0) \times E(0) \to E(0)$ given by concatenation of loops, which is associative up to coherent homotopy. However, much more is true: the identifications $E(0) \simeq \Omega^n E(n)$ show that $E(0)$ has the structure of an $n$-fold loop space for each $n \geq 0$. This structure allows us to view $E(0)$ as a commutative monoid object of the $\infty$-category $\text{Sp}$ of spaces. In fact, there is a converse to this observation: the construction $\{E(n)\} \mapsto E(0)$ determines an equivalence between the full subcategory $\text{Sp}^{cn} \subseteq \text{Sp}$ of connective spectra and the $\infty$-category $\text{Mon}^\text{gp}_{\text{Comm}}(\mathcal{S})$ of grouplike commutative monoids in $\mathcal{S}$ (see §5.2.6 for further discussion). This provides an algebraic way of thinking about the $\infty$-category of spectra: roughly speaking, the $\infty$-category of spectra bears the same relationship to the $\infty$-category of spaces as the ordinary category of abelian groups bears to the ordinary category of sets. Later in this book, we will elaborate on this analogy by describing homotopy-theoretic analogues of the theory of commutative and associative rings.

Our goal in this section is to provide a quick introduction to stable homotopy theory by elaborating on perspectives (A) through (C) (we will return to (D) briefly later in the book, once we have the technology to discuss algebraic structures in an $\infty$-categorical context; see Remark 5.2.6.26). We will begin in §1.4.1 with a review of Brown’s representability theorem. More precisely, we will show that if $\mathcal{C}$ is a pointed $\infty$-category satisfying some mild hypotheses, then it is possible to give necessary and sufficient conditions for a functor $F : \mathcal{H}C \to \text{Set}$ to be representable by an object of $\mathcal{C}$. We can apply this to give a classification of cohomology theories on $\mathcal{C}$ in terms of infinite loop objects of $\mathcal{C}$: that is, sequences of objects $\{E(n) \in \mathcal{C}\}_{n \in \mathbb{Z}}$ equipped with equivalences $E(n) \simeq \Omega E(n+1)$. The collection of such infinite loop objects can be organized into an $\infty$-category $\text{Sp}(\mathcal{C})$: we will refer to $\text{Sp}(\mathcal{C})$ as the $\infty$-category of spectrum objects of $\mathcal{C}$. We will define this $\infty$-category in §1.4.2, and show that it is a stable $\infty$-category. Of greatest interest to us is the case where $\mathcal{C}$ is the $\infty$-category $\text{Sp}$ of spaces. In this case, we will denote the $\infty$-category $\text{Sp}(\mathcal{C})$ by $\text{Sp}$, and refer to it as the $\infty$-category of spectra. We will study this $\infty$-category in §1.4.3, and show that it can be identified with the $\infty$-category $\text{Ind}(\text{Sp}^{cn})$, described in (A).

It should be emphasized that there are many definitions of the stable homotopy category $\text{hSp}$ in the literature, some of which look quite different from the definition given in this book. To facilitate the comparison of our approach with others, it is convenient to have not only a construction of the $\infty$-category $\text{Sp}$, but also an abstract characterization of it. We will provide such a characterization by showing that $\text{Sp}(\mathcal{C})$ is in some sense universal among stable $\infty$-categories equipped with a forgetful functor $\text{Sp}(\mathcal{C}) \to \mathcal{C}$ (Corollary 1.4.2.23).

There is another characterization of the $\infty$-category $\text{Sp}$ which is worthy of mention: among stable $\infty$-categories, it is freely generated by one object (the sphere spectrum) under small colimits. We will prove this result in §1.4.4 (see Corollary 1.4.4.6), after embarking on a general study of the behavior of colimits in stable $\infty$-categories.
1.4.1 The Brown Representability Theorem

Let $\mathcal{D}$ be a category. A functor $F : \mathcal{D}^{\text{op}} \to \text{Set}$ is said to be representable if there exists an object $X \in \mathcal{D}$ and a point $\eta \in F(X)$ which induces bijections $\text{Hom}_\mathcal{D}(Y,X) \to F(Y)$ for every object $Y \in \mathcal{D}$. If we assume that the category $\mathcal{D}$ is presentable, then the functor $F$ is representable if and only if it carries colimits in $\mathcal{D}$ to limits in $\text{Set}$ (see Proposition T.5.5.2.2). Our goal in this section is to study representability in a slightly different situation: namely, we will suppose that $\mathcal{D}$ is given as the homotopy category of a presentable $\infty$-category $\mathcal{C}$. In this case, the category $\mathcal{D}$ need not admit colimits. Nevertheless, one can often characterize the representable functors on $\mathcal{D}$ in terms of the behavior with respect to colimits in the underlying $\infty$-category $\mathcal{C}$.

We begin by recalling a bit of terminology. Let $\mathcal{D}$ be a category which admits finite coproducts. A cogroup object of $\mathcal{D}$ is an object $X \in \mathcal{D}$ equipped with a comultiplication $X \to X \sqcup X$ with the following property: for every object $Y \in \mathcal{D}$, the induced multiplication $\text{Hom}_\mathcal{D}(X,Y) \times \text{Hom}_\mathcal{D}(X,Y) \cong \text{Hom}_\mathcal{D}(X \sqcup X,Y)$ determines a group structure on the set $\text{Hom}_\mathcal{D}(X,Y)$.

Example 1.4.1.1. Let $\mathcal{C}$ be an $\infty$-category which admits finite colimits, let $\emptyset$ denote the initial object of $\mathcal{C}$, and suppose we are given a map $\epsilon : X \to \emptyset$. Then the pushout $\Sigma(X) = \emptyset \sqcup X \emptyset$ is a cogroup object of the homotopy category $h\mathcal{C}$. Namely, there is a “fold” map $\Sigma(X) \sqcup \Sigma(X) \cong \emptyset \sqcup X \emptyset \to \emptyset \sqcup X \emptyset \cong \emptyset \sqcup X \emptyset$ which, for every object $Y \in \mathcal{C}$, induces the canonical group structure on the set $\text{Hom}_{h\mathcal{C}}(\Sigma(X),Y) \cong \pi_1(\text{Map}_{\mathcal{C}}(X,Y),f)$. Here $f \in \text{Map}_{\mathcal{C}}(X,Y)$ is the point given by the composition $X \xrightarrow{\epsilon} \emptyset \to Y$.

The main result of this section is the following:

Theorem 1.4.1.2 (Brown Representability). Let $\mathcal{C}$ be a presentable $\infty$-category containing a set of objects $\{S_\alpha\}_{\alpha \in \Lambda}$ with the following properties:

(i) Each object $S_\alpha$ is a cogroup object of the homotopy category $h\mathcal{C}$.

(ii) Each object $S_\alpha \in \mathcal{C}$ is compact.

(iii) The $\infty$-category $\mathcal{C}$ is generated by the objects $S_\alpha$ under small colimits.

Then a functor $F : h\mathcal{C}^{\text{op}} \to \text{Set}$ is representable if and only if it satisfies the following conditions:

(a) For every collection of objects $C_\beta$ in $\mathcal{C}$, the map $F(\prod_\beta C_\beta) \to \prod_\beta F(C_\beta)$ is a bijection.

(b) For every pushout square

\[
\begin{array}{ccc}
  C \rightarrowtail & C' \\
\downarrow & \downarrow \\
  D \\ & \llongrightarrow \\
\end{array}
\]

in $\mathcal{C}$, the induced map $F(D') \to F(C') \times_{F(C)} F(D)$ is surjective.

We will give the proof of Theorem 1.4.1.2 at the end of this section.

Example 1.4.1.3. Let $\mathcal{C}$ be a presentable stable $\infty$-category. Then the homotopy category of $\mathcal{C}$ is additive (Lemma 1.1.2.10), so every object of $\mathcal{C}$ is a cogroup object of $h\mathcal{C}$. If $\mathcal{C}$ is compactly generated, then it satisfies the hypotheses of Theorem 1.4.1.2.
1.4. SPECTRA AND STABILIZATION

Example 1.4.1.4. Let $S_*$ denote the ∞-category of pointed spaces, and let $\mathcal{S}_{\geq 1}^*$ denote the full subcategory spanned by the connected spaces. We claim that $\mathcal{S}_{\geq 1}^*$ satisfies the hypotheses of Theorem 1.4.1.2: that is, $\mathcal{S}_{\geq 1}^*$ is generated under colimits by connective cogroup objects. In fact, $\mathcal{S}_{\geq 1}^*$ is generated under colimits by the 1-sphere $S^1$ (which corepresents the group-valued functor $X \mapsto \pi_1(X)$, and is therefore a cogroup object of the homotopy category $h\mathcal{S}_{\geq 1}^*$). This is equivalent to the assertion that a map of connected pointed spaces $f : X \to Y$ is a homotopy equivalence if and only if the induced map $\text{Map}_{\mathcal{S}_*}(S^1, X) \to \text{Map}_{\mathcal{S}_*}(S^1, Y)$ is a homotopy equivalence. This is clear, since we have isomorphisms

$$\pi_n X \simeq \pi_{n-1} \text{Map}_{\mathcal{S}_*}(S^1, X) \quad \pi_n Y \simeq \pi_{n-1} \text{Map}_{\mathcal{S}_*}(S^1, Y)$$

for $n > 0$.

Remark 1.4.1.5. In the special case $\mathcal{C} = \mathcal{S}_{\geq 0}^*$, the conclusion of Theorem 1.4.1.2 reproduces the classical Brown representability theorem (see [27]).

We now discuss some consequences of Theorem 1.4.1.2 for the classification of cohomology theories.

Definition 1.4.1.6. Let $\mathcal{C}$ be a pointed ∞-category which admits small colimits and let $\Sigma : \mathcal{C} \to \mathcal{C}$ be the suspension functor. A cohomology theory on $\mathcal{C}$ is a sequence of functors $\{H^n : h\mathcal{C}^{\text{op}} \to \text{Set}\}_{n \in \mathbb{Z}}$ together with isomorphisms $\delta^n : H^n \simeq H^{n+1} \circ \Sigma$, satisfying the following pair of conditions:

1. For every collection of objects $\{C_n\}$ in $\mathcal{C}$, the canonical map $H^n(\bigcoprod C_n) \to \prod H^n(C_n)$ is a bijection. In particular, if $*$ denotes a zero object of $\mathcal{C}$, then $H^n(*)$ consists of a single point. For any object $C \in \mathcal{C}$, the canonical map $C \to *$ induces a map $H^n(*) \to H^n(C)$ which we can identify with an element $0 \in H^n(C)$.

2. Suppose we are given a cofiber sequence

$$C' \to C \to C''$$

in the ∞-category $\mathcal{C}$. If $\eta \in H^n(C)$ has image 0 in $H^n(C')$, then $\eta$ lies in the image of the map $H^n(C'') \to H^n(C)$.

Remark 1.4.1.7. Let $\mathcal{C}$ be a pointed ∞-category which admits small colimits, and let $C$ be an object of $\mathcal{C}$. The two-fold suspension $\Sigma^2(C)$ is a commutative cogroup object of the homotopy category $h\mathcal{C}$ (we have canonical isomorphisms $\text{Hom}_{h\mathcal{C}}(\Sigma^2(C), D) \simeq \pi_2 \text{Map}_{\mathcal{C}}(C, D)$). Let $\{H^n, \delta^n\}$ be a cohomology theory on $\mathcal{C}$. Since the functor $H^{n+2}$ carries coproducts in $h\mathcal{C}$ to products of sets, it carries commutative cogroup objects of $h\mathcal{C}$ to abelian groups. In particular, for every object $C \in \mathcal{C}$, the set $H^n(C) \simeq H^{n+2}(\Sigma^2(C))$ has the structure of an abelian group, depending functorially on the object $C$: that is, we can regard each $H^n$ as a functor from the homotopy category $h\mathcal{C}$ to the category of abelian groups. In particular, for every object $C \in \mathcal{C}$, the map $H^n(*) \to H^n(C)$ carries the unique element of $H^n(*)$ to the identity element $0 \in H^n(C)$.

Remark 1.4.1.8. Let $\mathcal{C}$ be a pointed ∞-category which admits small colimits, and suppose we are given a cofiber sequence $C' \xrightarrow{f} C \xrightarrow{g} C''$ in $\mathcal{C}$. Such a triangle induces a map $C'' \to \Sigma(C')$, well-defined up to homotopy. If we are given a cohomology theory $\{H^n, \delta^n\}$ on $\mathcal{C}$, we obtain a boundary map

$$\partial : H^n(C') \xrightarrow{\delta^n} H^{n+1}(\Sigma(C')) \to H^{n+1}(C'').$$

These boundary maps can be used to splice together a sequence of abelian groups

$$\cdots \to H^{n-1}(C') \xrightarrow{\delta} H^n(C') \xrightarrow{\partial} H^n(C) \xrightarrow{g^*} H^n(C) \xrightarrow{f^*} H^n(C') \xrightarrow{\delta} H^{n+1}(C'') \to \cdots$$

We claim that this sequence is exact. Exactness at $H^n(C)$ follows immediately from condition (2) of Definition 1.4.1.6. Exactness at $H^n(C'')$ follows by applying the same argument to the cofiber sequence $C \to C'' \to \Sigma(C')$ (which gives rise to the same abelian groups and the same group homomorphisms up to sign, by virtue of Lemma 1.1.2.14), and exactness at $H^n(C')$ follows by applying the same argument to the cofiber sequence $C'' \to \Sigma(C') \to \Sigma(C)$.
Let $E$ be a pointed $\infty$-category which admits small colimits, and let $\{H^n, \delta^n\}$ be a cohomology theory on $C$. Then each of the functors $H^n : hC^{op} \to \text{Set}$ satisfies conditions (a) and (b) of Theorem 1.4.1.2. Condition (a) is obvious. To prove (b), suppose we are given a pushout square
\[ \begin{array}{ccc} C & \xrightarrow{f} & C' \\ \downarrow & & \downarrow \\ D & \xrightarrow{g} & D' \end{array} \]

Let $E = \text{cofib}(f) \simeq \text{cofib}(g)$. Using Remark 1.4.1.8, we get a map of exact sequences
\[ H^n(E) \longrightarrow H^n(D') \longrightarrow H^n(D) \longrightarrow H^{n+1}(E) \]
\[ H^n(E) \longrightarrow H^n(C') \longrightarrow H^n(C) \longrightarrow H^{n+1}(E). \]

Using the injectivity of $\psi$ and the surjectivity of $\phi$, we deduce that the map $H^n(D') \to H^n(C') \times_{H^n(C)} H^n(D)$ is surjective.

Combining Remark 1.4.1.9 with Theorem 1.4.1.2, we obtain the following result:

**Corollary 1.4.1.10.** Let $C$ be a presentable pointed $\infty$-category. Assume that $C$ is generated under colimits by compact objects which are cogroup objects of the homotopy category $hC$, and let $\{H^n, \delta^n\}$ be a cohomology theory on $C$. Then for every integer $n$, the functor $H^n : hC^{op} \to \text{Set}$ is representable by an object $E(n) \in C$.

**Remark 1.4.1.11.** In the situation of Corollary 1.4.1.10, the isomorphisms $\delta^n : H^n \simeq H^{n+1} \circ \Sigma$ determine canonical isomorphisms $E(n) \simeq \Omega E(n+1)$ in the homotopy category $hC$. Choosing equivalences in $C$ which represent these isomorphisms, we can promote the sequence $\{E(n)\}$ to an object $E$ in the homotopy limit $\text{Sp}(C)$ of the tower
\[ \ldots \to \Omega \to \Omega \to \Omega \to \Omega \to \ldots \]

The object $E$ is well-defined up to (non-unique) isomorphism in the homotopy category $h\text{Sp}(C)$. We will return to the study of the $\infty$-category $\text{Sp}(C)$ in §1.4.2.

**Proof of Theorem 1.4.1.2.** The necessity of conditions (a) and (b) is obvious. We will prove that these conditions are sufficient. Let $\emptyset$ denote an initial object of $C$. If $S$ is an object of $C$ equipped with a map $\epsilon : S \to \emptyset$, we define the suspension $\Sigma(S)$ to be the pushout $\emptyset \amalg S \emptyset$, so that $\Sigma(S)$ has the structure of a cogroup in $hC$ (Example 1.4.1.1). Each of the objects $S_\alpha$ is equipped with a counit map $S_\alpha \to \emptyset$ (by virtue of (i)), so that the suspension $\Sigma(S_\alpha)$ is well-defined. Enlarging the collection $\{S_\alpha\}$ if necessary, we may assume that this collection is stable under the formation of suspensions.

We first prove the following:

(+) Let $f : C \to C'$ be a morphism in $C$ such that the induced map $\text{Hom}_{hC}(S_\alpha, C) \to \text{Hom}_{hC}(S_\alpha, C')$ is an isomorphism, for every index $\alpha$. Then $f$ is an equivalence in $C$.

To prove (+), it will suffice to show that for every object $X \in C$, the map $f$ induces a homotopy equivalence $\phi_X : \text{Map}_C(X, C) \to \text{Map}_C(X, C')$. Let $C'$ denote the full subcategory of $C$ spanned by those objects $X$ for which $\phi_X$ is an equivalence. The full subcategory $C' \subseteq C$ is stable under colimits; we wish to prove that $C' = C$. By virtue of assumption (iii), it suffices to show that each of the objects $S_\alpha$ belongs to $C'$. Since $S_\alpha$ is a cogroup object of $hC$, $\phi_{S_\alpha}$ is a map between group objects of the homotopy category $\mathcal{H}$ of spaces. It follows that $\phi_{S_\alpha}$ is a homotopy equivalence if and only if it induces an isomorphism of groups $\pi_n \text{Map}_C(X, C) \to \pi_n \text{Map}_C(X, C')$ for each $n \geq 0$ (here the homotopy groups are taken with respect to the base points given by the group structures). Replacing $S_\alpha$ by $\Sigma(S_\alpha)$, we can reduce to the case $n = 0$: that is, to the bijectivity of the maps $\text{Hom}_{hC}(S_\alpha, C) \to \text{Hom}_{hC}(S_\alpha, C')$.

Now suppose that $F$ is a functor satisfying conditions (a) and (b). We will prove the following:
1.4. SPECTRA AND STABILIZATION

(*') Let $X \in \mathcal{C}$ and let $\eta \in F(X)$. Then there exists a map $f : X \to X'$ in $\mathcal{C}$ and an object $\eta' \in F(X')$ lifting $\eta$ with the following property: for every index $\alpha \in A$, $\eta'$ induces a bijection $\operatorname{Hom}_{h\mathcal{C}}(S_{\alpha}, X') \to F(S_{\alpha})$.

To prove (*'), we begin by defining $X_0$ to be the coproduct of $X$ with $\coprod_{\alpha \in A} C_{\alpha}$. Using (a), we deduce the existence of an element $\eta_0 \in F(X_0)$ lifting $\eta$. By construction, $\eta_0$ induces a surjection $\operatorname{Hom}_{h\mathcal{C}}(S_{\alpha}, X_0) \to F(S_{\alpha})$ for each index $\alpha$.

We now define a sequence of morphisms $X_0 \to X_1 \to X_2 \to \cdots$ and a compatible family of elements $\eta_n \in F(X_n)$ using induction on $n$. Suppose that $X_n$ and $\eta_n$ have already been constructed. For each index $\alpha \in A$, let $K_{\alpha}$ be the kernel of the group homomorphism $\operatorname{Hom}_{h\mathcal{C}}(S_{\alpha}, X_n) \to F(S_{\alpha})$, and define $X_{n+1}$ to fit into a pushout diagram

$$\begin{array}{ccc}
\coprod_{\alpha \in A, \gamma \in K_{\alpha}} S_{\alpha} & \longrightarrow & \emptyset \\
\downarrow & & \downarrow \\
X_n & \longrightarrow & X_{n+1}
\end{array}$$

where the upper horizontal map is given by the counit on each $S_{\alpha}$. The existence of a point $\eta_{n+1} \in F(X_{n+1})$ lifting $\eta_n$ follows from assumption (a).

Let $X' = \lim_{\to n} X_n$. We have a pushout diagram

$$\begin{array}{ccc}
\coprod_n X_n & \longrightarrow & \coprod_n X_{2n} \\
\downarrow & & \downarrow \\
\coprod_n X_{2n+1} & \longrightarrow & X'.
\end{array}$$

Using (a) and (b), we deduce the existence of a point $\eta' \in F(X')$ lifting the sequence $\{\eta_n \in F(X_n)\}$. We claim that $\eta'$ satisfies the condition described in (*). Fix an index $\alpha$; we wish to prove that the map $\psi : \operatorname{Hom}_{h\mathcal{C}}(S_{\alpha}, X') \to F(S_{\alpha})$ is bijective. It is clear that $\psi$ is surjective (since the composite map $\operatorname{Hom}_{h\mathcal{C}}(S_{\alpha}, X_0) \to \operatorname{Hom}_{h\mathcal{C}}(S_{\alpha}, X') \to F(S_{\alpha})$ is surjective by construction). To prove that $\psi$ is injective, it will suffice to show that the kernel of $\psi$ is trivial (since $\psi$ is a group homomorphism, using the cogroup structure on $S_{\alpha}$ given by (i)). Fix an element $\gamma \in \ker(\psi)$, represented by a map $f : S_{\alpha} \to X'$. Assumption (ii) guarantees that $S_{\alpha}$ is compact, so that $f$ factors through some map $\overline{f} : S_{\alpha} \to X_n$, which determines an element of the kernel $K$ of the map $\operatorname{Hom}_{h\mathcal{C}}(S_{\alpha}, X_n) \to F(S_{\alpha})$. It follows from our construction that the composite map $S_{\alpha} \to X_n \to X_{n+1}$ factors through the counit of $S_{\alpha}$, so that $f$ is the unit element of $\ker(\psi)$. This completes the proof of (*').

Assertion (b) guarantees that $F(\emptyset)$ consists of a single element. Applying (*') in the case $X = \emptyset$, we obtain an element $\eta'' \in F(X')$ which induces isomorphisms $\operatorname{Hom}_{h\mathcal{C}}(S_{\alpha}, X') \to F(S_{\alpha})$ for each index $\alpha$. We will complete the proof by showing that $\eta''$ exhibits $F$ as the functor on $h\mathcal{C}$ represented by the object $X'$. In other words, we claim that for every object $Y \in \mathcal{C}$, the element $\eta''$ induces a bijection $\theta : \operatorname{Hom}_{h\mathcal{C}}(Y, X') \to F(Y)$.

We begin by showing that $\theta$ is surjective. Fix an element $\eta'' \in F(Y)$. Assumption (b) guarantees that $(\eta'', \eta'')$ determines an element of $F(Y \coprod X')$. Applying assertion (*') to this element, we deduce the existence of a map $X' \coprod Y \to Z$ and an element $\eta \in F(Z)$ lifting the pair $(\eta', \eta'')$ which induces isomorphisms $\operatorname{Hom}_{h\mathcal{C}}(S_{\alpha}, Z) \to F(S_{\alpha})$ for each index $\alpha$. We have a commutative diagram

$$\begin{array}{ccc}
\operatorname{Map}_{h\mathcal{C}}(S_{\alpha}, X') & \longrightarrow & \operatorname{Map}_{h\mathcal{C}}(S_{\alpha}, Z) \\
\downarrow & & \downarrow \\
F(S_{\alpha}) & \longrightarrow & F(S_{\alpha})
\end{array}$$

for each index $\alpha$, in which the vertical maps are bijective. It follows that the horizontal map is also bijective. Invoking (*), we deduce that $X' \to Z$ is an equivalence. The composite map $Y \to Z \simeq X'$ is then a preimage of $\eta''$ in the set $\operatorname{Hom}_{h\mathcal{C}}(Y, X')$. 
We now complete the proof by showing that \( \theta \) is injective. Fix a pair of maps \( f, g : Y \to X' \) which determine the same element of \( F(Y) \). Form a pushout diagram

\[
\begin{array}{ccc}
Y & \xrightarrow{(f,g)} & X' \\
\downarrow & & \downarrow \\
Y & \longrightarrow & Z.
\end{array}
\]

Using assumption \((b)\), we deduce that \( \eta' \in F(X') \) can be lifted to an element \( \eta \in F(Z) \). Applying \((*)\), we deduce the existence of a map \( Z \to Z' \) and an element \( \eta' \in F(Z') \) lifting \( \eta \) and inducing bijections \( \Hom_{h\mathcal{C}}(S_\alpha, Z') \to F(S_\alpha) \) for each index \( \alpha \). We have commutative diagrams

\[
\begin{array}{ccc}
\Map_{h\mathcal{C}}(S_\alpha, X') & \longrightarrow & \Map_{h\mathcal{C}}(S_\alpha, Z') \\
\downarrow & & \downarrow \\
F(S_\alpha) & & 
\end{array}
\]

in which the vertical maps are bijective. It follows that the horizontal maps are also bijective, so that \((*)\) guarantees that the map \( h : X' \to Z' \) is an equivalence in \( \mathcal{C} \). Since the compositions \( h \circ f \) and \( h \circ g \) are homotopic, we deduce that \( f \) and \( g \) are homotopic and therefore represent the same element of \( \Hom_{h\mathcal{C}}(Y, X') \), as desired. \( \square \)

### 1.4.2 Spectrum Objects

In this section, we will describe a method for constructing stable \( \infty \)-categories: for any \( \infty \)-category \( \mathcal{C} \) which admits finite limits, one can consider an \( \infty \)-category \( \mathrm{Sp}(\mathcal{C}) \) of spectrum objects of \( \mathcal{C} \). In the special case where \( \mathcal{C} \) is the \( \infty \)-category of spaces, this construction will recover classical stable homotopy theory; we will discuss this example in more detail in \( \S 1.4.3 \).

If the \( \infty \)-category \( \mathcal{C} \) is pointed, then the \( \infty \)-category \( \mathrm{Sp}(\mathcal{C}) \) of spectrum objects of \( \mathcal{C} \) can be described as the homotopy inverse limit of the tower of \( \infty \)-categories

\[
\cdots \to \mathcal{C} \xrightarrow{\Omega} \mathcal{C} \xrightarrow{\Omega} \mathcal{C}.
\]

As we saw in \( \S 1.4.1 \), the objects of this homotopy inverse limit are closely related to cohomology theories defined on the \( \infty \)-category \( \mathcal{C} \). In this section, it will be more convenient to adopt a dual perspective: we will identify spectrum objects of \( \mathcal{C} \) with homology theories defined on pointed spaces, taking values in \( \mathcal{C} \).

Before giving any formal definitions, let us consider the most classical example of a homology theory: the singular homology of topological spaces. This theory associates to every topological space \( X \) the singular homology groups \( H_n(X; \mathbb{Z}) \). These groups are covariantly functorial in \( X \), and have the following additional property: for every pair of open sets \( U, V \subseteq X \) which cover \( X \), we have a long exact Mayer-Vietoris sequence

\[
\cdots \to H_1(U; \mathbb{Z}) \oplus H_1(V; \mathbb{Z}) \to H_1(X; \mathbb{Z}) \to H_0(U \cap V; \mathbb{Z}) \to H_0(U; \mathbb{Z}) \oplus H_0(V; \mathbb{Z}) \to H_0(X; \mathbb{Z}) \to 0.
\]

Note that the singular homology \( H_n(X; \mathbb{Z}) \) can be defined as the homology of the (normalized or unnormalized) chain complex associated to the simplicial abelian group \( \mathbb{Z} \text{Sing}(X)_\bullet \) freely generated by the simplicial set \( \text{Sing}(X)_\bullet \). As such, they can be viewed as the homotopy groups of \( \mathbb{Z} \text{Sing}(X)_\bullet \), regarded as a Kan complex. The above long exact sequence results from the observation that that diagram

\[
\begin{array}{ccc}
\mathbb{Z} \text{Sing}(U \cap V)_\bullet & \longrightarrow & \mathbb{Z} \text{Sing}(U)_\bullet \\
\downarrow & & \downarrow \\
\mathbb{Z} \text{Sing}(V)_\bullet & \longrightarrow & \mathbb{Z} \text{Sing}(X)_\bullet.
\end{array}
\]
is a homotopy pullback square of Kan complexes. This is a consequence of the following more general fact: 
the construction $X \mapsto \mathbb{Z} \text{Sing}(X)_*$ carries homotopy pushout diagrams (of topological spaces) to homotopy pullback diagrams (of Kan complexes). We now proceed to axiomatize this phenomenon:

**Definition 1.4.2.1.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor between $\infty$-categories.

(i) If $\mathcal{C}$ admits pushouts, then we will say that $F$ is **excisive** if $F$ carries pushout squares in $\mathcal{C}$ to pullback squares in $\mathcal{D}$.

(ii) If $\mathcal{C}$ admits a final object $*$, we will say that $F$ is **reduced** if $F(*)$ is a final object of $\mathcal{D}$.

If $\mathcal{C}$ admits pushouts, we let $\text{Exc}(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the excisive functors. If $\mathcal{C}$ admits a final object, we let $\text{Fun}_*(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by the reduced functors. If $\mathcal{C}$ admits pushouts and a final object, we let $\text{Exc}_*(\mathcal{C}, \mathcal{D})$ denote the intersection $\text{Exc}(\mathcal{C}, \mathcal{D}) \cap \text{Fun}_*(\mathcal{C}, \mathcal{D})$.

**Remark 1.4.2.2.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor between $\infty$-categories, and suppose that $\mathcal{C}$ is a pointed $\infty$-category which admits finite colimits. If $\mathcal{C}$ is stable, then $F$ is reduced and excisive if and only if it is left exact (Proposition 1.1.3.4). If instead $\mathcal{D}$ is stable, then $F$ is reduced and excisive if and only if it is right exact. In particular, if both $\mathcal{C}$ and $\mathcal{D}$ are stable, then $F$ is reduced and excisive if and only if it is exact (Proposition 1.1.4.1).

**Remark 1.4.2.3.** Let $K$ be a simplicial set, let $\mathcal{C}$ be an $\infty$-category which admits pushouts, and let $\mathcal{D}$ be an $\infty$-category which admits $K$-indexed limits. Then $\text{Fun}(\mathcal{C}, \mathcal{D})$ admits $K$-indexed limits. Moreover, the collection of excisive functors from $\mathcal{C}$ to $\mathcal{D}$ is closed under $K$-indexed limits. Similarly, if $\mathcal{C}$ has a final object $*$, the the full subcategory $\text{Fun}_*(\mathcal{C}, \mathcal{D}) \subseteq \text{Fun}(\mathcal{C}, \mathcal{D})$ is closed under $K$-indexed limits.

**Remark 1.4.2.4.** Suppose that $\mathcal{C}$ is a small pointed $\infty$-category which admits finite colimits, and let $\mathcal{D}$ be a presentable $\infty$-category. Then $\text{Fun}_*(\mathcal{C}, \mathcal{D})$, $\text{Exc}(\mathcal{C}, \mathcal{D})$, and $\text{Exc}_*(\mathcal{C}, \mathcal{D})$ are accessible localizations of the $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{D})$ (Lemmas T.5.5.4.18 and T.5.5.4.19). In particular, each is a presentable $\infty$-category.

**Notation 1.4.2.5.** Let $S_*$ denote the $\infty$-category of pointed objects of $S$. That is, $S_*$ denotes the full subcategory of $\text{Fun}(\Delta^1, S)$ spanned by those morphisms $f : X \to Y$ for which $X$ is a final object of $S$ (Definition T.7.2.2.1). Let $S_{\text{fin}}$ denote the smallest full subcategory of $S$ which contains the final object $*$ and is stable under finite colimits. We will refer to $S_{\text{fin}}$ as the $\infty$-category of finite spaces. We let $S_{\text{fin}}^* \subseteq S_*$ denote the $\infty$-category of pointed objects of $S_{\text{fin}}$. We observe that the suspension functor $\Sigma : S_* \to S_*$ carries $S_{\text{fin}}^*$ to itself. For each $n \geq 0$, we let $S^n \subseteq S_*$ denote a representative for the (pointed) $n$-sphere.

**Remark 1.4.2.6.** It follows from Remark T.5.3.5.9 and Proposition T.4.3.2.15 that $S_{\text{fin}}$ is characterized by the following universal property: for every $\infty$-category $\mathcal{D}$ which admits finite colimits, evaluation at $*$ induces an equivalence of $\infty$-categories $\text{Fun}^{\text{Rex}}(S_{\text{fin}}, \mathcal{D}) \to \mathcal{D}$. Here $\text{Fun}^{\text{Rex}}(S_{\text{fin}}, \mathcal{D})$ denotes the full subcategory of $\text{Fun}(S_{\text{fin}}, \mathcal{D})$ spanned by the right exact functors. More informally: the $\infty$-category $S_{\text{fin}}$ is freely generated by a single object (the space $*$) under finite colimits.

**Warning 1.4.2.7.** The $\infty$-category $S_{\text{fin}}$ does not coincide with the $\infty$-category of compact objects $S^c \subseteq S$. Instead, there is an inclusion $S_{\text{fin}} \subseteq S^c$, which realizes $S^c$ as an idempotent completion of $S_{\text{fin}}$. An object of $X \in S^c$ belongs to $S_{\text{fin}}$ if and only if its *Wall finiteness obstruction* vanishes. We refer the reader to [159] for further details.

**Definition 1.4.2.8.** Let $\mathcal{C}$ be an $\infty$-category which admits finite limits. A **spectrum object** of $\mathcal{C}$ is a reduced, excisive functor $X : S^*_{\text{fin}} \to \mathcal{C}$. Let $\text{Sp}(\mathcal{C}) = \text{Exc}_*(S^*_{\text{fin}}, \mathcal{C})$ denote the full subcategory of $\text{Fun}(S^*_{\text{fin}}, \mathcal{C})$ spanned by the spectrum objects of $\mathcal{C}$.

**Remark 1.4.2.9.** Let $\mathcal{C}$ be an $\infty$-category which admits finite limits, and $K$ an arbitrary simplicial set. Then we have a canonical isomorphism $\text{Sp}(\text{Fun}(K, \mathcal{C})) \simeq \text{Fun}(K, \text{Sp}(\mathcal{C}))$. 

1.4. SPECTRA AND STABILIZATION

117
We next show that if \( \mathcal{C} \) is an \( \infty \)-category which admits finite limits, then the \( \infty \)-category \( \text{Sp}(\mathcal{C}) \) is stable. We begin with the following observation:

**Lemma 1.4.2.10.** Let \( \mathcal{C} \) be a pointed \( \infty \)-category which admits finite colimits, and let \( \mathcal{D} \) be an \( \infty \)-category which admits finite limits. Then the \( \infty \)-category \( \text{Exc}_{\ast}(\mathcal{C}, \mathcal{D}) \) is pointed and admits finite limits.

**Proof.** The existence of finite limits in \( \text{Exc}_{\ast}(\mathcal{C}, \mathcal{D}) \) follows from Remark 1.4.2.3. Let \( \ast \) denote a final object of \( \mathcal{C} \) and \( \ast' \) a final object of \( \mathcal{D} \). Let \( X : \mathcal{C} \to \mathcal{D} \) be the constant functor taking the value \( \ast' \). Then \( X \) is a final object of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \), and in particular a final object of \( \text{Exc}_{\ast}(\mathcal{C}, \mathcal{D}) \). We claim that \( X \) is also an initial object of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \) (and in particular an initial object of \( \text{Exc}_{\ast}(\mathcal{C}, \mathcal{D}) \)). To prove this, choose any other object \( Y \in \text{Fun}(\mathcal{C}, \mathcal{D}) \); we wish to show that the mapping space \( \text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(X, Y) \) is contractible. Since the functor \( Y \) is reduced, the mapping space \( \text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(X(\ast), Y(\ast)) \) is contractible. It will therefore suffice to show that the restriction map \( \text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(X, Y) \to \text{Map}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(X(\ast), Y(\ast)) \) is a homotopy equivalence. This follows from the observation that \( X \) is a left Kan extension of its restriction along the inclusion \( \{\ast\} \to \mathcal{C} \). \( \square \)

We will deduce the stability of \( \text{Sp}(\mathcal{C}) \) using the following general criterion:

**Proposition 1.4.2.11.** Let \( \mathcal{C} \) be a pointed \( \infty \)-category which admits finite colimits, \( \mathcal{D} \) a pointed \( \infty \)-category which admits finite limits, and let \( F : \mathcal{C} \to \mathcal{D} \) be a reduced functor. The following conditions are equivalent:

1. The suspension functor \( \Sigma_{\mathcal{C}} \) is fully faithful, then every pushout square in \( \mathcal{C} \) is a pullback square.
2. The loop functor \( \Omega_{\mathcal{C}} \) is fully faithful, then every pullback square in \( \mathcal{C} \) is a pushout square.
3. If the loop functor \( \Omega_{\mathcal{C}} \) is an equivalence of \( \infty \)-categories, then \( \mathcal{C} \) is stable.

We will deduce Proposition 1.4.2.11 from a more general assertion regarding functors between pointed \( \infty \)-categories. The formulation of this result will require a bit of terminology.

**Notation 1.4.2.12.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor between \( \infty \)-categories, and assume that \( \mathcal{D} \) admits finite limits. For every commutative square \( \tau : W \to X \)

\[
\begin{array}{ccc}
W & \to & X \\
\downarrow & & \downarrow \\
Y & \to & Z
\end{array}
\]

in \( \mathcal{C} \), we obtain a commutative square \( F(\tau) : F(W) \to F(X) \)

\[
\begin{array}{ccc}
F(W) & \to & F(X) \\
\downarrow & & \downarrow \\
F(Y) & \to & F(Z)
\end{array}
\]

in \( \mathcal{D} \). This diagram determines a map \( \eta_{\tau} : F(W) \to F(X) \times_{F(Z)} F(Y) \) in the \( \infty \)-category \( \mathcal{D} \), which is well-defined up to homotopy. If we suppose further that \( X \) and \( Y \) are zero objects of \( \mathcal{C} \), that \( F(X) \) and \( F(Y) \) are zero objects of \( \mathcal{D} \), and that \( \tau \) is a pushout diagram, then we obtain a map \( F(W) \to \Omega_{\mathcal{D}} F(\Sigma_{\mathcal{C}} W) \), which we will denote simply by \( \eta_{W} \).

**Proposition 1.4.2.13.** Let \( \mathcal{C} \) be a pointed \( \infty \)-category which admits finite colimits, \( \mathcal{D} \) a pointed \( \infty \)-category which admits finite limits, and let \( F : \mathcal{C} \to \mathcal{D} \) a reduced functor. The following conditions are equivalent:

1. The functor \( F \) is excisive (Definition 1.4.2.1): that is, \( F \) carries pushout squares in \( \mathcal{C} \) to pullback squares in \( \mathcal{D} \).
(2) For every object \( X \in \mathcal{C} \), the canonical map \( \eta_X : F(X) \to \Omega_D F(\Sigma_W X) \) is an equivalence in \( D \) (see Notation 1.4.2.12).

Assuming Proposition 1.4.2.13 for the moment, it is easy to verify Proposition 1.4.2.11:

Proof of Proposition 1.4.2.11. Assertion (1) follows by applying Proposition 1.4.2.13 to the identity functor \( \text{id}_C \), and assertion (2) follows from (1) by passing to the opposite \( \infty \)-category. Assertion (3) is an immediate consequence of (1) and (2) (note that if \( \Omega_C \) is an equivalence of \( \infty \)-categories, then its left adjoint \( \Sigma_C \) is also an equivalence of \( \infty \)-categories).

 Restricting our attention to stable \( \infty \)-categories, Proposition 1.4.2.13 yields the following:

Corollary 1.4.2.14. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor between stable \( \infty \)-categories. Then \( F \) is exact if and only if the following conditions are satisfied:

(1) The functor \( F \) carries zero objects of \( \mathcal{C} \) to zero objects of \( \mathcal{D} \).

(2) For every object \( X \in \mathcal{C} \), the canonical map \( \Sigma_D F(X) \to F(\Sigma_W X) \) is an equivalence in \( D \).

The proof of Proposition 1.4.2.13 makes use of the following lemma:

Lemma 1.4.2.15. Let \( \mathcal{C} \) be a pointed \( \infty \)-category which admits finite colimits, \( \mathcal{D} \) a pointed \( \infty \)-category which admits finite limits, and \( F : \mathcal{C} \to \mathcal{D} \) a reduced functor. Suppose given a pushout diagram \( \tau \):

\[
\begin{array}{ccc}
W & \to & X \\
\downarrow & & \downarrow \\
Y & \to & Z
\end{array}
\]

in \( \mathcal{C} \). Then there exists a map \( \theta_\tau : F(X) \times_{F(Y)} F(Y) \to \Omega_D F(\Sigma_W W) \) with the following properties:

(1) The composition \( \theta_\tau \circ \eta_P \) is homotopic to \( \eta_W \). Here \( \eta_P \) and \( \eta_W \) are defined as in Notation 1.4.2.12.

(2) Let \( \Sigma_C(\tau) \) denote the induced diagram

\[
\begin{array}{ccc}
\Sigma_W W & \to & \Sigma_W X \\
\downarrow & & \downarrow \\
\Sigma_P Y & \to & \Sigma_P Z.
\end{array}
\]

Then there is a pullback square

\[
\begin{array}{ccc}
\eta_{\Sigma_C(\tau)} & \circ & \theta_\tau \\
\downarrow & & \downarrow \\
\eta_Y & \to & \eta_Z
\end{array}
\]

in the \( \infty \)-category \( \text{Fun}(\Delta^1, \mathcal{D}) \) of morphisms in \( \mathcal{D} \).

Proof. In the \( \infty \)-category \( \mathcal{C} \), we have the following commutative diagram (in which every square is a pushout):

\[
\begin{array}{ccccccccccc}
W & \to & X & \to & 0 \\
\downarrow & & \downarrow & & \downarrow \\
Y & \to & X \amalg_W Y & \to & 0 \amalg_W Y & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \to & X \amalg_W 0 & \to & \Sigma_W W & \to & \Sigma_W Y \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \to & \Sigma_W X & \to & \Sigma_W (X \amalg_W Y).
\end{array}
\]
Applying the functor $F$, and replacing the upper left square by a pullback, we obtain a new diagram
\[
\begin{array}{ccc}
F(X) \times_{F(Z)} F(Y) & \longrightarrow & F(X) \\
\downarrow & & \downarrow 0 \\
F(Y) & \longrightarrow & F(Z) \\
\downarrow & & \downarrow 0 \\
0 & \longrightarrow & F(0 \amalg_W Y) \\
\downarrow & & \downarrow 0 \\
F(X \amalg_W 0) & \longrightarrow & F(\Sigma e W) \\
\downarrow & & \downarrow 0 \\
0 & \longrightarrow & F(\Sigma e X) \\
\end{array}
\]

Restricting attention to the large square in the upper left, we obtain the desired map $\theta \mathrel{\simeq} F(X) \times_{F(Z)} F(Y) \rightarrow \Omega_D F(\Sigma e W)$. It is easy to verify that $\theta$ has the desired properties.

**Proof of Proposition 1.4.2.13.** The implication (1) $\Rightarrow$ (2) is obvious. Conversely, suppose that (2) is satisfied. We must show that for every pushout square $\tau$:
\[
\begin{array}{ccc}
X & \longrightarrow & Y \\
\downarrow & & \downarrow \\
Z & \longrightarrow & Y \amalg_X Z
\end{array}
\]
in the $\infty$-category $\mathcal{C}$, the induced map $\eta$ is an equivalence in $\mathcal{D}$. Let $\theta$ be as in the statement of Lemma 1.4.2.15. Then $\tau \circ \eta$ is homotopic to $\eta\mathcal{X}$, and is therefore an equivalence (by virtue of assumption (2)). It will therefore suffice to show that $\tau$ is an equivalence. The preceding argument shows that $\theta$ has a right homotopy inverse. To show that $\theta$ admits a left homotopy inverse, it will suffice to show that $\eta\mathcal{X} \circ \theta$ is an equivalence. This follows from the second assertion of Lemma 1.4.2.15, since the maps $\eta_Y$, $\eta_Z$, and $\eta_{Y \amalg_X Z}$ are equivalences (by assumption (2)).

**Proposition 1.4.2.16.** Let $\mathcal{C}$ be a pointed $\infty$-category which admits finite colimits and $\mathcal{D}$ an $\infty$-category which admits finite limits. Then the $\infty$-category $\text{Exc}_c(\mathcal{C}, \mathcal{D})$ is stable.

**Proof.** We may assume without loss of generality that $\mathcal{C}$ is small. Suppose first that $\mathcal{D}$ is presentable. Let $S : \text{Fun}(\mathcal{C}, \mathcal{D}) \rightarrow \text{Fun}(\mathcal{C}, \mathcal{D})$ be given by $F \mapsto F \circ \Sigma e$, where $\Sigma e : \mathcal{C} \rightarrow \mathcal{C}$ denotes the suspension functor. Then $S$ carries $\text{Exc}_c(\mathcal{C}, \mathcal{D})$ to itself. Using the definition of excisive functors, we conclude that $S$ is a homotopy inverse to the functor $\Omega_{\text{Exc}_c(\mathcal{C}, \mathcal{D})}$. Since $\text{Exc}_c(\mathcal{C}, \mathcal{D})$ is pointed (Lemma 1.4.2.10) and admits finite limits and colimits (Remark 1.4.2.4), we conclude from Proposition 1.4.2.11 that it is stable.

To handle the general case, we may assume without loss of generality that $\mathcal{D}$ is small. Let $\mathcal{D}' = \mathcal{P}(\mathcal{D})$ be the $\infty$-category of presheaves on $\mathcal{D}$ and let $j : \mathcal{D} \rightarrow \mathcal{D}'$ be the Yoneda embedding. Since $j$ is left exact, it induces a fully faithful embedding $\text{Exc}_c(\mathcal{C}, \mathcal{D}) \rightarrow \text{Exc}_c(\mathcal{C}, \mathcal{D}')$. Then $\text{Exc}_c(\mathcal{C}, \mathcal{D})$ is equivalent to a full subcategory of the stable $\infty$-category $\text{Exc}_c(\mathcal{C}, \mathcal{D}')$, which is closed under finite limits and suspensions. It follows from Lemma 1.1.3.3 that $\text{Exc}_c(\mathcal{C}, \mathcal{D})$ is stable.

**Corollary 1.4.2.17.** Let $\mathcal{C}$ be an $\infty$-category which admits finite limits. Then the $\infty$-category $\text{Sp}(\mathcal{C})$ of spectrum objects of $\mathcal{C}$ is stable.

**Remark 1.4.2.18.** Let $\mathcal{C}$ be an $\infty$-category which admits finite limits, and let $\mathcal{C}_o$ denote the $\infty$-category of pointed objects of $\mathcal{C}$. Then the forgetful functor $\mathcal{C}_o \rightarrow \mathcal{C}$ induces an equivalence of $\infty$-categories $\text{Sp}(\mathcal{C}_o) \rightarrow \text{Sp}(\mathcal{C})$. To see this, we observe that there is a canonical isomorphism of simplicial sets $\text{Sp}(\mathcal{C}_o) \simeq \text{Sp}(\mathcal{C})_o$. We are therefore reduced to proving that the forgetful functor $\text{Sp}(\mathcal{C}_o) \rightarrow \text{Sp}(\mathcal{C})$ is an equivalence of $\infty$-categories, which follows from the fact that $\text{Sp}(\mathcal{C})$ is pointed (Corollary 1.4.2.17).
1.4. SPECTRA AND STABILIZATION

Our next goal is to characterize the ∞-category \( \text{Sp}(\mathcal{C}) \) by means of a universal property.

**Lemma 1.4.2.19.** Let \( \mathcal{C} \) be an ∞-category which admits finite colimits and a final object, let \( f : \mathcal{C} \to \mathcal{C}_* \) be a left adjoint to the forgetful functor, and let \( \mathcal{D} \) be a stable ∞-category. Let \( \text{Exc}'(\mathcal{C}, \mathcal{D}) \) denote the full subcategory of \( \text{Exc}(\mathcal{C}, \mathcal{D}) \) spanned by those functors which carry the initial object of \( \mathcal{C} \) to a final object of \( \mathcal{D} \). Then composition with \( f \) induces an equivalence of ∞-categories \( \phi : \text{Exc}_*(\mathcal{C}_*, \mathcal{D}) \to \text{Exc}'(\mathcal{C}, \mathcal{D}) \).

**Proof.** Consider the composite functor

\[
\theta : \text{Fun}(\mathcal{C}, \mathcal{D}) \times \mathcal{C}_* \subseteq \text{Fun}(\mathcal{C}, \mathcal{D}) \times \text{Fun}(\Delta^1, \mathcal{C}) \to \text{Fun}(\Delta^1, \mathcal{D}) \xrightarrow{\text{cofib}} \mathcal{D}.
\]

We can identify \( \theta \) with a map \( \text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}_*, \mathcal{D}) \). Since the collection of pullback squares in \( \mathcal{D} \) is a stable subcategory of \( \text{Fun}(\Delta^1 \times \Delta^1, \mathcal{D}) \), we conclude \( \theta \) restricts to a map \( \psi : \text{Exc}'(\mathcal{C}, \mathcal{D}) \to \text{Exc}_*(\mathcal{C}_*, \mathcal{D}) \). It is not difficult to verify that \( \psi \) is a homotopy inverse to \( \phi \).

**Notation 1.4.2.20.** Let \( S^0 \) denote the 0-sphere, regarded as an object of the ∞-category \( S_{\text{fin}}^* \) of pointed finite spaces. If \( \mathcal{C} \) is an ∞-category which admits finite limits, we let \( \Omega^{\infty} : \text{Sp}(\mathcal{C}) \to \mathcal{C} \) denote the functor given by evaluation at \( S^0 \in S_{\text{fin}}^* \). More generally, in \( n \in \mathbb{Z} \) is an integer, we let \( \Omega^{\infty-n} : \text{Sp}(\mathcal{C}) \to \mathcal{C} \) denote the functor given by composing \( \Omega^{\infty} : \text{Sp}(\mathcal{C}) \to \mathcal{C} \) with the shift functor \( X \mapsto X[n] \) on \( \text{Sp}(\mathcal{C}) \) (if \( n \geq 0 \), then the functor \( \Omega^{\infty-n} : \text{Sp}(\mathcal{C}) \to \mathcal{C} \) is given by evaluation on the n-sphere \( S^n \)).

**Proposition 1.4.2.21.** Let \( \mathcal{D} \) be an ∞-category which admits finite limits. The following conditions are equivalent:

1. The ∞-category \( \mathcal{D} \) is stable.
2. The functor \( \Omega^{\infty} : \text{Sp}(\mathcal{D}) \to \mathcal{D} \) is an equivalence of ∞-categories.

**Proof.** The implication (2) \( \Rightarrow \) (1) follows from Corollary 1.4.2.17. Conversely, suppose that (1) is satisfied, and let \( f : S_{\text{fin}}^n \to S_{\text{fin}}^m \) be a left adjoint to the forgetful functor (obtained by adding a disjoint base point). Using Lemma 1.4.2.19, we are reduced to proving that evaluation at the object \( * \in S_{\text{fin}}^n \) induces an equivalence of ∞-categories \( \text{Exc}'(S_{\text{fin}}^n, \mathcal{D}) \). Note that a functor \( X : S_{\text{fin}}^n \to \mathcal{D} \) belongs to \( \text{Exc}'(S_{\text{fin}}^n, \mathcal{D}) \) if and only if it is right exact. The desired result now follows from Remark 1.4.2.6.

**Proposition 1.4.2.22.** Let \( \mathcal{C} \) be an pointed ∞-category which admits finite colimits and \( \mathcal{D} \) an ∞-category which admits finite limits. Then composition with the functor \( \Omega^{\infty} : \text{Sp}(\mathcal{D}) \to \mathcal{D} \) induces an equivalence of ∞-categories

\[
\theta : \text{Exc}_*(\mathcal{C}, \text{Sp}(\mathcal{D})) \to \text{Exc}_*(\mathcal{C}, \mathcal{D})
\]

**Proof.** Under the canonical isomorphism \( \text{Exc}_*(\mathcal{C}, \text{Sp}(\mathcal{D})) \simeq \text{Sp}(\text{Exc}_*(\mathcal{C}, \mathcal{D})) \), the functor \( \theta \) corresponds to evaluation map \( \Omega^{\infty} : \text{Sp}(\text{Exc}_*(\mathcal{C}, \mathcal{D})) \to \text{Exc}_*(\mathcal{C}, \mathcal{D}) \). Since \( \text{Exc}_*(\mathcal{C}, \mathcal{D}) \) is stable by Proposition 1.4.2.16, Proposition 1.4.2.21 implies that \( \theta \) is an equivalence of ∞-categories.

**Corollary 1.4.2.23.** Let \( \mathcal{C} \) be a stable ∞-category, let \( \mathcal{D} \) an ∞-category which admits finite limits, and let

\[
\text{Fun}'(\mathcal{C}, \mathcal{D}) \subseteq \text{Fun}(\mathcal{C}, \mathcal{D}) \quad \text{Fun}'(\mathcal{C}, \text{Sp}(\mathcal{D})) \subseteq \text{Fun}(\mathcal{C}, \text{Sp}(\mathcal{D}))
\]

denote the full subcategories spanned by the left-exact functors. Then composition with the functor \( \Omega^{\infty} : \text{Sp}(\mathcal{D}) \to \mathcal{D} \) induces an equivalence of ∞-categories

\[
\text{Fun}'(\mathcal{C}, \text{Sp}(\mathcal{D})) \to \text{Fun}'(\mathcal{C}, \mathcal{D})
\]

**Proposition 1.4.2.24.** Let \( \mathcal{C} \) be a pointed ∞-category which admits finite limits. Then the functor \( \Omega^{\infty} : \text{Sp}(\mathcal{C}) \to \mathcal{C} \) can be lifted to an equivalence of \( \text{Sp}(\mathcal{C}) \) with the homotopy limit of the tower of ∞-categories

\[
\ldots \to \mathcal{C} \xrightarrow{\Omega^1} \mathcal{C} \xrightarrow{\Omega^2} \ldots
\]
Remark 1.4.2.25. Let $\mathcal{C}$ be an $\infty$-category which admits finite limits. Combining Remark 1.4.2.18 with Proposition 1.4.2.24, we can identify the $\infty$-category $\text{Sp}(\mathcal{C})$ of spectrum objects of $\mathcal{C}$ with the homotopy limit of the tower

\[ \cdots \to \mathcal{C}_* \xrightarrow{\Omega} \mathcal{C}_* \xrightarrow{\Omega} \mathcal{C}_*. \]

Lemma 1.4.2.26. Let $\mathcal{C}$ be a small pointed $\infty$-category, and let $\mathcal{P}_+(\mathcal{C})$ denote the full subcategory of $\mathcal{P}(\mathcal{C}) = \text{Fun}(\mathcal{C}^{op}, S)$ spanned by those functors which carry zero objects of $\mathcal{C}$ to final objects of $S$. Then:

1. Let $S$ denote the set consisting of a single morphism from an initial object of $\mathcal{P}(\mathcal{C})$ to a final object of $\mathcal{P}(\mathcal{C})$. Then $\mathcal{P}_+(\mathcal{C}) = S^{-1} \mathcal{P}(\mathcal{C})$.
2. The $\infty$-category $\mathcal{P}_+(\mathcal{C})$ is an accessible localization of $\mathcal{P}(\mathcal{C})$. In particular, $\mathcal{P}_+(\mathcal{C})$ is presentable.
3. The Yoneda embedding $\mathcal{C} \to \mathcal{P}(\mathcal{C})$ factors through $\mathcal{P}_+(\mathcal{C})$, and the induced embedding $j : \mathcal{C} \to \mathcal{P}_+(\mathcal{C})$ preserves zero objects.
4. Let $\mathcal{D}$ be an $\infty$-category which admits small colimits, and let $\text{Fun}^L(\mathcal{P}_+(\mathcal{C}), \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{P}_+(\mathcal{C}), \mathcal{D})$ spanned by those functors which preserve small colimits. Then composition with $j$ induces an equivalence of $\infty$-categories $\text{Fun}^L(\mathcal{P}_+(\mathcal{C}), \mathcal{D}) \to \text{Fun}_0(\mathcal{C}, \mathcal{D})$, where $\text{Fun}_0(\mathcal{C}, \mathcal{D})$ denotes the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which carry zero objects of $\mathcal{C}$ to initial objects of $\mathcal{D}$.
5. The $\infty$-category $\mathcal{P}_+(\mathcal{C})$ is pointed.
6. The full subcategory $\mathcal{P}_+(\mathcal{C}) \subseteq \mathcal{P}(\mathcal{C})$ is closed under small limits and under small colimits parametrized by weakly contractible simplicial sets. In particular, $\mathcal{P}_+(\mathcal{C})$ is stable under small filtered colimits in $\mathcal{P}(\mathcal{C})$.
7. The functor $j : \mathcal{C} \to \mathcal{P}_+(\mathcal{C})$ preserves all small limits which exist in $\mathcal{C}$.
8. The $\infty$-category $\mathcal{P}_+(\mathcal{C})$ is compactly generated.

Proof. For every object $X \in S$, let $F_X \in \mathcal{P}(\mathcal{C})$ denote the constant functor taking the value $X$. Then $F_X$ is a left Kan extension of $F_{\emptyset} : \{\emptyset\} \to \mathcal{P}(\mathcal{C})$, where $\emptyset$ denotes a zero object of $\mathcal{C}$. It follows that for any object $G \in \mathcal{P}(\mathcal{C})$, evaluation at $0$ induces a homotopy equivalence

\[ \text{Map}_{\mathcal{P}(\mathcal{C})}(F_X, G) \to \text{Map}_S(F_X(0), G(0)) = \text{Map}_S(X, G(0)). \]

We observe that the inclusion $0 \subseteq \Delta^0$ induces a map $F_\emptyset \to F_{\Delta^0}$ from an initial object of $\mathcal{P}(\mathcal{C})$ to a final object of $\mathcal{P}(\mathcal{C})$. It follows that an object $G$ of $\mathcal{P}(\mathcal{C})$ is $S$-local if and only if the induced map

\[ G(0) \simeq \text{Map}_S(\Delta^0, G(0)) \to \text{Map}_S(0, G(0)) \simeq \Delta^0 \]

is a homotopy equivalence: that is, if and only if $G \in \mathcal{P}_+(\mathcal{C})$. This proves (1).

Assertion (2) follows immediately from (1), and assertion (3) is obvious. Assertion (4) follows from (1), Theorem T.5.1.5.6, and Proposition T.5.5.4.20. To prove (5), we observe that $F_{\Delta^0}$ is a final object of $\mathcal{P}(\mathcal{C})$, and therefore a final object of $\mathcal{P}_+(\mathcal{C})$. It therefore suffices to show that $F_{\Delta^0}$ is an initial object of $\mathcal{P}_+(\mathcal{C})$. This follows from the observation that for every $G \in \mathcal{P}(\mathcal{C})$, we have homotopy equivalences $\text{Map}_{\mathcal{P}_+(\mathcal{C})}(F_{\Delta^0}, G) \simeq \text{Map}_S(\Delta^0, G(0)) \simeq G(0)$ so that the mapping space $\text{Map}_{\mathcal{P}_+(\mathcal{C})}(F_{\Delta^0}, G)$ is contractible if $G \in \mathcal{P}_+(\mathcal{C})$. Assertion (6) is obvious, and (7) follows from (6) together with Proposition T.5.1.3.2. We deduce (8) from (6) together with Corollary T.5.5.7.3.

Proof of Proposition 1.4.2.24. Let $\overline{\mathcal{C}}$ denote a homotopy limit of the tower

\[ \cdots \to \mathcal{C} \xrightarrow{\Omega} \mathcal{C} \xrightarrow{\Omega} \mathcal{C}. \]
We begin by showing that $C$ is a stable $\infty$-category.

Assume first that $C$ is presentable. Applying Theorem T.5.5.3.18, we deduce that $C$ is presentable. In particular, $C$ admits small limits and colimits. By construction, $C$ is pointed and the loop functor $\Omega_C$ is an equivalence of $\infty$-categories. Applying Proposition 1.4.2.11, we deduce that $C$ is stable.

We now prove that $C$ is stable in general. Without loss of generality, we may assume that $C$ is small. Let $j : C \to \mathcal{P}_*(C)$ be as in Lemma 1.4.2.26, and let $\mathcal{P}_*(C)$ denote a homotopy limit of the tower $\cdots \to \mathcal{P}_*(C) \overset{\Omega}{\to} \mathcal{P}_*(C) \overset{\Omega}{\to} \mathcal{P}_*(C) \overset{\Omega}{\to} \mathcal{P}_*(C)$.

The functor $j$ is fully faithful and left exact, and therefore induces a fully faithful left exact embedding $C \to \mathcal{P}_*(C)$. Then $C$ is closed under finite limits and shifts in the stable $\infty$-category $\mathcal{P}_*(C)$, and is therefore stable by Lemma 1.1.3.3.

Let $G : C \to C$ be the canonical map. Then $G$ is left exact. Applying Corollary 1.4.2.23, we deduce that $G'$ induces an equivalence $\mathrm{Fun}'(\mathcal{D}, \mathcal{C}) \to \mathrm{Fun}'(\mathcal{D}, \mathcal{P}(\mathcal{C}))$, where $\mathrm{Fun}'(\mathcal{D}, \mathcal{X})$ denotes the full subcategory of $\mathrm{Fun}(\mathcal{D}, \mathcal{X})$ spanned by the left exact functors. Using Corollary 1.4.2.23, we are reduced to proving that composition with $G'$ induces an equivalence $\mathrm{Fun}'(\mathcal{D}, \mathcal{C}) \to \mathrm{Fun}'(\mathcal{D}, \mathcal{Sp}(\mathcal{C}))$.

Using Proposition 1.4.2.24, we can obtain a slight improvement on Proposition 1.4.2.11:

**Corollary 1.4.2.27.** Let $\mathcal{C}$ be a pointed $\infty$-category. The following conditions are equivalent:

1. The $\infty$-category $\mathcal{C}$ is stable.

2. The $\infty$-category $\mathcal{C}$ admits finite colimits and the suspension functor $\Sigma_C : \mathcal{C} \to \mathcal{C}$ is an equivalence.

3. The $\infty$-category $\mathcal{C}$ admits finite limits and the loop functor $\Omega_C : \mathcal{C} \to \mathcal{C}$ is an equivalence.

**Proof.** We will show that $(1) \iff (3)$; the dual argument will prove that $(1) \iff (2)$. The implication $(1) \Rightarrow (3)$ is clear. Conversely, suppose that $\mathcal{C}$ admits finite limits and that $\Omega_C$ is an equivalence. Proposition 1.4.2.24 implies that $\mathcal{P}(\mathcal{C})$ can be identified with the homotopy inverse limit of the tower $\cdots \overset{\Omega}{\to} \mathcal{C} \overset{\Omega}{\to} \mathcal{C} \overset{\Omega}{\to} \mathcal{C}$. If $(3)$ is satisfied, then the loop functor $\Omega_C$ is an equivalence, so this tower is essentially constant. It follows that $\Omega^\infty : \mathcal{P}(\mathcal{C}) \to \mathcal{C}$ is an equivalence of $\infty$-categories. Since $\mathcal{P}(\mathcal{C})$ is stable (Corollary 1.4.2.17), so is $\mathcal{C}$.

### 1.4.3 The $\infty$-Category of Spectra

In this section, we will discuss what is perhaps the most important example of a stable $\infty$-category: the $\infty$-category of spectra. In classical homotopy theory, one defines a spectrum to be a sequence of pointed spaces $\{X_n\}_{n \geq 0}$, equipped with homotopy equivalences (or homeomorphisms, depending on the author) $X_n \to \Omega(X_{n+1})$ for all $n \geq 0$. By virtue of Remark 1.4.2.25, this admits the following $\infty$-categorical translation:
**Definition 1.4.3.1.** A *spectrum* is a spectrum object of the $\infty$-category $\mathcal{S}$ of spaces. We let $\mathrm{Sp} = \mathrm{Sp}(\mathcal{S})$ denote the $\infty$-category of spectra.

**Remark 1.4.3.2.** The homotopy category $\mathrm{hSp}$ of spectra can be identified with the classical stable homotopy category. There are many different constructions of the stable homotopy category in the literature. For a discussion of some other modern approaches, we refer the reader to [51] and [73].

**Remark 1.4.3.3.** According to Definition 1.4.3.1, a spectrum $E$ is a reduced, excisive functor from the $\infty$-category $\mathcal{S}^\mathrm{fin}$ of pointed finite spaces to the $\infty$-category $\mathcal{S}$ of spaces. As suggested in §1.4.2, we can think of such a functor as defining a homotopy theory $A$. More precisely, given a pair of finite spaces $X_0 \subseteq X$, we can define the relative homology group $A_\ast(X, X_0)$ to be $\pi_\ast E(X/X_0)$, where $X/X_0$ denotes the pointed space obtained from $X$ by collapsing $X_0$ to a point (here the homotopy group is taken with base point provided by the map $* \simeq E(*) \to E(X/X_0)$). The assumption that $E$ is excisive guarantees the existence of excision and Mayer-Vietoris sequences for $A$.

It follows from Corollary 1.4.2.17 that the $\infty$-category $\mathrm{Sp}$ of spectra is stable. To analyze this $\infty$-category further, we observe that there is a t-structure on $\mathrm{Sp}$. This is a special case of the following general observation:

**Proposition 1.4.3.4.** Let $\mathcal{C}$ be a presentable $\infty$-category, and let $\mathrm{Sp}(\mathcal{C})_{\leq -1}$ be the full subcategory of $\mathrm{Sp}(\mathcal{C})$ spanned by those objects $X$ such that $\Omega^\infty(X)$ is a final object of $\mathcal{C}$. Then $\mathrm{Sp}(\mathcal{C})_{\leq -1}$ determines an accessible t-structure on $\mathrm{Sp}(\mathcal{C})$ (see Definition 1.4.4.12).

**Proof.** Note that the forgetful functor $\Omega^\infty : \mathrm{Sp}(\mathcal{C}) \to \mathcal{C}$ is accessible and preserves small limits, and therefore admits a left adjoint $\Sigma^\infty_\mathcal{C}$ (Corollary T.5.5.2.9). Choose a small collection of objects $\{C_\alpha\}$ which generates $\mathcal{C}$ under colimits. We observe that an object $X \in \mathrm{Sp}(\mathcal{C})$ belongs to $\mathrm{Sp}(\mathcal{C})_{\leq -1}$ if and only if each of the spaces $\overline{\mathrm{Map}}_{\mathcal{C}}(C_\alpha, \Omega^\infty(X)) \simeq \overline{\mathrm{Map}}_{\mathrm{Sp}(\mathcal{C})}(\Sigma^\infty_\mathcal{C}(C_\alpha), X)$ is contractible. Let $\mathrm{Sp}(\mathcal{C})_{\geq 0}$ be the smallest full subcategory of $\mathrm{Sp}(\mathcal{C})$ which is stable under colimits and extensions, and contains each $\Sigma^\infty_\mathcal{C}(C_\alpha)$. Proposition 1.4.4.11 implies that $\mathrm{Sp}(\mathcal{C})_{\geq 0}$ is the collection of non-negative objects of the desired t-structure on $\mathrm{Sp}(\mathcal{C})$.

**Remark 1.4.3.5.** The proof of Proposition 1.4.3.4 gives another characterization of the t-structure on $\mathrm{Sp}(\mathcal{C})$: the full subcategory $\mathrm{Sp}(\mathcal{C})_{\geq 0}$ is generated, under extensions and colimits, by the essential image of the functor $\Sigma^\infty_+: \mathcal{C} \to \mathrm{Sp}(\mathcal{C})$.

We now apply Proposition 1.4.3.4 to the study of the $\infty$-category $\mathrm{Sp}$:

**Proposition 1.4.3.6.** (1) The $\infty$-category $\mathrm{Sp}$ is stable.

(2) Let $(\mathrm{Sp})_{\leq -1}$ denote the full subcategory of $\mathrm{Sp}$ spanned by those objects $X$ such that the space $\Omega^\infty(X) \in \mathcal{S}$ is contractible. Then $(\mathrm{Sp})_{\leq -1}$ determines an accessible t-structure on $\mathrm{Sp}$ (see Definition 1.4.4.12).

(3) The t-structure on $\mathrm{Sp}$ is both left complete and right complete, and the heart $\mathrm{Sp}^\heartsuit$ is canonically equivalent to the (nerve of the) category of abelian groups.

**Proof.** Assertion (1) follows immediately from Corollary 1.4.2.17 and assertion (2) from Proposition 1.4.3.4. We will prove (3). Note that a spectrum $X$ can be identified with a sequence of pointed spaces $\{X(n)\}$, equipped with equivalences $X(n) \simeq \Omega X(n+1)$ for all $n \geq 0$. We observe that $X \in (\mathrm{Sp})_{\leq m}$ if and only if each $X(n)$ is $(n + m)$-truncated. In general, the sequence $\{\tau_{\leq m}X(n)\}$ itself determines a spectrum, which we can identify with the truncation $\tau_{\leq m}X$. It follows that $X \in (\mathrm{Sp})_{\geq m+1}$ if and only if each $X(n)$ is $(n + m + 1)$-connective. In particular, $X$ lies in the heart of $\mathrm{Sp}$ if and only if each $X(n)$ is an Eilenberg-MacLane object of $\mathcal{S}$ of degree $n$ (see Definition T.7.2.2.1). It follows that the heart of $\mathrm{Sp}$ can be identified with the homotopy inverse limit of the tower of $\infty$-categories

$$
\cdots \Omega \mathcal{E} \mathcal{M}_1(\mathcal{S}) \rightarrow \Omega \mathcal{E} \mathcal{M}_0(\mathcal{S}),
$$
where $\mathcal{EM}_n(S)$ denotes the full subcategory of $S_n$ spanned by the Eilenberg-MacLane objects of degree $n$. Proposition T.7.2.2.12 asserts that after the second term, this tower is equivalent to the constant diagram taking the value $N(\mathbb{A}b)$, where $\mathbb{A}b$ is category of abelian groups.

It remains to prove that $\text{Sp}$ is both right and left complete. We begin by observing that if $X \in \text{Sp}$ is such that $\pi_nX \simeq 0$ for all $n \in \mathbb{Z}$, then $X$ is a zero object of $\text{Sp}$ (since each $X(n) \in \mathbb{S}$ has vanishing homotopy groups, and is therefore contractible by Whitehead’s theorem). Consequently, both $\bigcap \langle \text{Sp} \rangle_{\leq -n}$ and $\bigcap \langle \text{Sp} \rangle_{\geq n}$ coincide with the collection of zero objects of $\text{Sp}$. It follows that

$$(\text{Sp})_{\geq 0} = \{ X \in \text{Sp} : (\forall n < 0)[\pi_nX \simeq 0]\}$$

$$(\text{Sp})_{\leq 0} = \{ X \in \text{Sp} : (\forall n > 0)[\pi_nX \simeq 0]\}. $$

According to Proposition 1.2.1.19, to prove that $\text{Sp}$ is left and right complete it will suffice to show that the subcategories $(\text{Sp})_{\geq 0}$ and $(\text{Sp})_{\leq 0}$ are stable under products and coproducts. In view of the above formulas, it will suffice to show that the homotopy group functors $\pi_n : \text{Sp} \to N(\mathbb{A}b)$ preserve products and coproducts. Since $\pi_n$ obviously commutes with finite coproducts, it will suffice to show that $\pi_n$ commutes with products and filtered colimits. Shifting if necessary, we may reduce to the case $n = 0$. Since products and filtered colimits in the category of abelian groups can be computed at the level of the underlying sets, we are reduced to proving that the composition

$$\text{Sp} \xrightarrow{\Omega^\infty} S \xrightarrow{\pi_0} N(\text{Set})$$

preserves products and filtered colimits. This is clear, since each of the factors individually preserves products and filtered colimits.

Our next goal is to show that the $\infty$-category $\text{Sp}$ is compactly generated. This is a consequence of the following more general result:

**Proposition 1.4.3.7.** Let $\mathcal{C}$ be a compactly generated $\infty$-category. Then the $\infty$-category $\text{Sp}(\mathcal{C})$ is compactly generated.

**Proof.** Let $\mathcal{D}$ be the full subcategory of $\text{Sp}(\mathcal{C})$ spanned by the compact objects. Since $\text{Sp}(\mathcal{C})$ is presentable, the $\infty$-category $\mathcal{D}$ is essentially small. It follows that the inclusion $\mathcal{D} \to \text{Sp}(\mathcal{C})$ extends to a fully faithful embedding $\theta : \text{Ind}(\mathcal{D}) \to \text{Sp}(\mathcal{C})$ (Proposition T.5.3.5.10). We wish to show that $\theta$ is an equivalence of $\infty$-categories. Since $\theta$ preserves small colimits (Proposition T.5.5.1.9), it admits a right adjoint $G$; it will therefore suffice to show that $G$ is conservative. Let $\alpha : X \to Y$ be a morphism in $\text{Sp}(\mathcal{C})$ such that $G(\alpha)$ is an equivalence. We wish to show that $\alpha$ is an equivalence. For this, it will suffice to show that for every integer $n$, the induced map $\Omega^{n-1}X \to \Omega^{n-1}Y$ is an equivalence in $\mathcal{C}$. Since $\mathcal{C}$ is compactly generated, it will suffice to show that $\alpha$ induces a homotopy equivalence $\theta : \text{Map}_\mathcal{C}(C, \Omega^\infty X) \to \text{Map}_\mathcal{C}(C, \Omega^\infty Y)$ for every compact object $C \in \mathcal{C}$. To prove this, we note that filtered colimits in $\mathcal{C}$ are left exact, so that the full subcategory $\text{Sp}(\mathcal{C}) \subseteq \text{Fun}(\mathcal{S}_n, \mathcal{C})$ is closed under filtered colimits. It follows that the functor $\Omega^\infty : \text{Sp}(\mathcal{C}) \to \mathcal{C}$ admits a left adjoint $\Sigma^\infty : \mathcal{C} \to \text{Sp}(\mathcal{C})$ which carries compact objects of $\mathcal{C}$ to compact objects of $\text{Sp}(\mathcal{C})$. We can identify $\theta$ with the map $\text{Map}_{\text{Sp}(\mathcal{C})}(\Sigma^\infty(C), X) \to \text{Map}_{\text{Sp}(\mathcal{C})}(\Sigma^\infty(C), Y)$ given by composition with $\alpha$. Since $\Sigma^\infty(C)$ is compact, our assumption that $G(\alpha)$ is an equivalence guarantees that $\theta$ is a homotopy equivalence as desired. □

**Remark 1.4.3.8.** Let $\mathbb{A}b$ denote the category of abelian groups. For each $n \in \mathbb{Z}$, the construction $X \mapsto \pi_nX$ determines a functor $\text{Sp} \to N(\mathbb{A}b)$. Note that if $n \geq 2$, then $\pi_n$ can be identified with the composition $\text{Sp} \xrightarrow{\Omega^\infty} \mathcal{S}_n \xrightarrow{\pi_0} N(\mathbb{A}b)$ where the second map is the usual homotopy group functor. Since $\text{Sp}$ is both left and right complete, we conclude that a map $f : X \to Y$ of spectra is an equivalence if and only if it induces isomorphisms $\pi_n X \xrightarrow{\sim} \pi_n Y$ for all $n \in \mathbb{Z}$.
We close this section with the following useful result, which relates colimits in the \(\infty\)-categories \(Sp\) and \(S\):

**Proposition 1.4.3.9.** The functor \(\Omega^\infty : Sp_{\geq 0} \to S\) preserves sifted colimits.

**Proof.** Since every sifted simplicial set is weakly contractible, the forgetful functor \(S_* \to S\) preserves sifted colimits (Proposition T.4.4.2.9). It will therefore suffice to prove that the functor \(\Omega^\infty|_{Sp_{\geq 0}} \to S_*\) preserves sifted colimits.

For each \(n \geq 0\), let \(S_{\geq n}^\infty\) denote the full subcategory of \(S\) spanned by the \(n\)-connective objects, and let \(S_n^\infty\) be the \(\infty\)-category of pointed objects of \(S_{\geq n}^\infty\). We observe that \(Sp_{\geq 0}\) can be identified with the homotopy inverse limit of the tower

\[
\ldots \xrightarrow{\Omega} S_{n+1}^\infty \xrightarrow{\Omega} S_n^\infty.
\]

It will therefore suffice to prove that for every \(n \geq 0\), the loop functor \(\Omega : S_{n+1}^\infty \to S_n^\infty\) preserves sifted colimits.

The \(\infty\)-category \(S_{\geq n}^\infty\) is the preimage (under \(\tau_{\leq n-1}\)) of the full subcategory of \(\tau_{\leq n-1} S\) spanned by the final objects. Since this full subcategory is stable under sifted colimits and since \(\tau_{\leq n-1}\) commutes with all colimits, we conclude that \(S_{\geq n}^\infty \subseteq S\) is stable under sifted colimits.

According to Lemmas T.7.2.2.11 and T.7.2.2.10, there is an equivalence of \(S_{n+1}^\infty\) with the \(\infty\)-category of group objects \(\text{grp}(S_*)\). This restricts to an equivalence of \(S_n^\infty\) with \(\text{grp}(S_n^\infty)\) for all \(n \geq 0\). Moreover, under this equivalence, the loop functor \(\Omega\) can be identified with the composition

\[
\text{grp}(S_n^\infty) \subseteq \text{Fun}(N(\Delta)^{op}, S_{n}^\infty) \to S_n^\infty,
\]

where the second map is given by evaluation at the object \([1] \in \Delta\). This evaluation map commutes with sifted colimits (Proposition T.5.1.2.2). Consequently, it will suffice to show that \(\text{grp}(S_n^\infty) \subseteq \text{Fun}(N(\Delta)^{op}, S_{n}^\infty)\) is stable under sifted colimits.

Without loss of generality, we may suppose \(n = 0\); now we are reduced to showing that \(\text{grp}(S_*) \subseteq \text{Fun}(N(\Delta)^{op}, S_*)\) is stable under sifted colimits. In view of Lemma T.7.2.2.10, it will suffice to show that \(\text{grp}(S) \subseteq \text{Fun}(N(\Delta)^{op}, S)\) is stable under sifted colimits. Invoking Proposition T.7.2.2.4, we are reduced to proving that the formation of sifted colimits \(S\) commutes with finite products, which follows from Lemma T.5.5.8.11. \(\square\)

### 1.4.4 Presentable Stable \(\infty\)-Categories

In this section, we will study the class of presentable stable \(\infty\)-categories: that is, stable \(\infty\)-categories which admit small colimits and are generated (under colimits) by a set of small objects. In the stable setting, the condition of presentability can be formulated in a particularly simple way.

**Proposition 1.4.4.1.** (1) A stable \(\infty\)-category \(\mathcal{C}\) admits small colimits if and only if \(\mathcal{C}\) admits small coproducts.

(2) Let \(F : \mathcal{C} \to \mathcal{D}\) be an exact functor between stable \(\infty\)-categories which admit small colimits. Then \(F\) preserves small colimits if and only if \(F\) preserves small coproducts.

(3) Let \(\mathcal{C}\) be a stable \(\infty\)-category which admits small colimits, and let \(X\) be an object of \(\mathcal{C}\). Then \(X\) is compact if and only if the following condition is satisfied:

\((\ast)\) For every map \(f : X \to \coprod_{a \in A} Y_a\) in \(\mathcal{C}\), there exists a finite subset \(A_0 \subseteq A\) such that \(f\) factors (up to homotopy) through \(\coprod_{a \in A_0} Y_a\).

**Proof.** The “only if” direction of (1) is obvious, and the converse follows from Proposition T.4.4.3.2. Assertion (2) can be proven in the same way.

The “only if” direction of (3) follows from the fact that an arbitrary coproduct \(\coprod_{a \in A} Y_a\) can be obtained as a filtered colimit of finite coproducts \(\coprod_{a \in A_0} Y_a\) (see §T.4.2.3). Conversely, suppose that an object \(X \in \mathcal{C}\)
Suppose first that \( \hat{\mathcal{F}} \) denotes the \( \infty \)-category of spaces which are not necessarily small. Proposition T.5.1.3.2 implies that \( \hat{\mathcal{F}} \) is left exact. According to Proposition 1.4.2.22, we can assume that \( f = \Omega^\infty \circ F \), where \( F : \mathcal{C} \to \hat{\mathcal{S}}_p \) is an exact functor; here \( \mathcal{S}_p \) denotes the \( \infty \)-category of spectra which are not necessarily small. We wish to prove that \( f \) preserves filtered colimits. Since \( \Omega^\infty \) preserves filtered colimits, it will suffice to show that \( F \) preserves all colimits. In view of (2), it will suffice to show that \( F \) preserves coproducts. In virtue of Remark 1.4.3.8, we are reduced to showing that each of the induced functors

\[
\mathcal{C} \xrightarrow{F} \mathcal{S}_p \xrightarrow{\hat{\pi}} \text{N}(Ab)
\]

preserves coproducts, where \( Ab \) denotes the category of (not necessarily small) abelian groups. Shifting if necessary, we may suppose \( n = 0 \). In other words, we must show that for any collection of objects \( \{Y_\alpha\}_{\alpha \in A} \), the natural map

\[
\theta : \bigoplus \text{Ext}_\mathcal{C}^0(X, Y_\alpha) \to \text{Ext}_\pi^0(X, \prod Y_\alpha)
\]

is an isomorphism of abelian groups. The surjectivity of \( \theta \) amounts to the assumption (\( * \)), while the injectivity follows from the observations that each \( Y_\alpha \) is a retract of the coproduct \( \prod Y_\alpha \) and that the natural map \( \bigoplus \text{Ext}_\mathcal{C}^0(X, Y_\alpha) \to \prod \text{Ext}_\mathcal{C}^0(X, Y_\alpha) \) is injective. \( \square \)

If \( \mathcal{C} \) is a stable \( \infty \)-category, then we will say that an object \( X \in \mathcal{C} \) generates \( \mathcal{C} \) if the condition \( \pi_0 \text{Map}_\mathcal{C}(X, Y) \simeq * \) implies that \( Y \) is a zero object of \( \mathcal{C} \).

**Corollary 1.4.4.2.** Let \( \mathcal{C} \) be a stable \( \infty \)-category. Then \( \mathcal{C} \) is presentable if and only if the following conditions are satisfied:

1. The \( \infty \)-category \( \mathcal{C} \) admits small coproducts.
2. The homotopy category \( \pi \mathcal{C} \) is locally small.
3. There exists a regular cardinal \( \kappa \) and a \( \kappa \)-compact generator \( X \in \mathcal{C} \).

**Proof.** Suppose first that \( \mathcal{C} \) is presentable. Conditions (1) and (2) are obvious. To establish (3), we may assume without loss of generality that \( \mathcal{C} \) is an accessible localization of \( \mathcal{P}(\mathcal{D}) \), for some small \( \infty \)-category \( \mathcal{D} \). Let \( F : \mathcal{P}(\mathcal{D}) \to \mathcal{C} \) be the localization functor and \( G \) its right adjoint. Let \( j : \mathcal{D} \to \mathcal{P}(\mathcal{D}) \) be the Yoneda embedding, and let \( X \) be a coproduct of all suspensions (see §1.1.2) of objects of the form \( F(j(D)) \), where \( D \in \mathcal{D} \). Since \( \mathcal{C} \) is presentable, \( X \) is \( \kappa \)-compact provided that \( \kappa \) is sufficiently large. We claim that \( X \) generates \( \mathcal{C} \). To prove this, we consider an arbitrary \( Y \in \mathcal{C} \) such that \( \pi_0 \text{Map}_\mathcal{C}(X, Y) \simeq * \). It follows that the space

\[
\text{Map}_\mathcal{C}(F(j(D)), Y) \simeq \text{Map}_{\mathcal{P}(\mathcal{D})}(j(D), G(Y)) \simeq G(Y)(D)
\]

is contractible for all \( D \in \mathcal{D} \), so that \( G(Y) \) is a final object of \( \mathcal{P}(\mathcal{D}) \). Since \( G \) is fully faithful, we conclude that \( Y \) is a final object of \( \mathcal{C} \), as desired.

Conversely, suppose that (1), (2), and (3) are satisfied. We first claim that \( \mathcal{C} \) is itself locally small. It will suffice to show that for every morphism \( f : X \to Y \) in \( \mathcal{C} \) and every \( n \geq 0 \), the homotopy group \( \pi_n(\text{Hom}_\mathcal{C}^\bigoplus(X, Y), f) \) is small. We note that \( \text{Hom}_\mathcal{C}^\bigoplus(X, Y) \) is equivalent to the loop space of \( \text{Hom}_\mathcal{C}^\bigoplus(X, Y[1]) \); the question is therefore independent of base point, so we may assume that \( f \) is the zero map. We conclude that the relevant homotopy group can be identified with \( \text{Hom}_{h\mathcal{C}}(X[n], Y) \), which is small by virtue of assumption (2).

Fix a regular cardinal \( \kappa \) and a \( \kappa \)-compact object \( X \) which generates \( \mathcal{C} \). We now define a transfinite sequence of full subcategories

\[
\mathcal{C}(0) \subseteq \mathcal{C}(1) \subseteq \ldots
\]

as follows. Let \( \mathcal{C}(0) \) be the full subcategory of \( \mathcal{C} \) spanned by the objects \( \{X[n]\}_{n \in \mathbb{Z}} \). If \( \lambda \) is a limit ordinal, let \( \mathcal{C}(\lambda) = \bigcup_{\beta < \lambda} \mathcal{C}(\beta) \). Finally, let \( \mathcal{C}(\alpha + 1) \) be the full subcategory of \( \mathcal{C} \) spanned by all objects which can
be obtained as the colimit of \(\kappa\)-small diagrams in \(\mathcal{C}(\kappa)\). Since \(\mathcal{C}\) is locally small, it follows that each \(\mathcal{C}(\kappa)\) is essentially small. It follows by induction that each \(\mathcal{C}(\kappa)\) consists of \(\kappa\)-compact objects of \(\mathcal{C}\) and is stable under translation. Finally, we observe that \(\mathcal{C}(\kappa)\) is stable under \(\kappa\)-small colimits. It follows from Lemma 1.1.3.3 that \(\mathcal{C}(\kappa)\) is a stable subcategory of \(\mathcal{C}\). Choose a small \(\infty\)-category \(\mathcal{D}\) and an equivalence \(f : \mathcal{D} \to \mathcal{C}(\kappa)\). According to Proposition T.5.3.5.11, we may suppose that \(f\) factors as a composition

\[
\mathcal{D} \xrightarrow{j} \text{Ind}_\kappa(\mathcal{D}) \xrightarrow{F} \mathcal{C}
\]

where \(j\) is the Yoneda embedding and \(F\) is a \(\kappa\)-continuous, fully faithful functor. We will complete the proof by showing that \(F\) is an equivalence.

Proposition T.5.5.1.9 implies that \(F\) preserves small colimits. It follows that \(F\) admits a right adjoint \(G : \mathcal{C} \to \text{Ind}_\kappa(\mathcal{D})\) (Remark T.5.5.2.10). We wish to show that the counit map \(u : F \circ G \to \text{id}_\mathcal{C}\) is an equivalence of functors. Choose an object \(Z \in \mathcal{C}\), and let \(Y\) be a cofiber for the induced map \(u_Z : (F \circ G)(Z) \to Z\). Since \(F\) is fully faithful, \(G(u_Z)\) is an equivalence. Because \(G\) is an exact functor, we deduce that \(G(Y) = 0\). It follows that \(\text{Map}_\mathcal{C}(F(D), Y) \simeq \text{Map}_{\text{Ind}_\kappa(\mathcal{D})}(D, G(Y)) \simeq \ast\) for all \(D \in \text{Ind}_\kappa(\mathcal{D})\). In particular, we conclude that \(\pi_0 \text{Map}_\mathcal{C}(X, Y) \simeq \ast\). Since \(X\) generates \(\mathcal{C}\), we deduce that \(Y \simeq 0\). Thus \(u_Z\) is an equivalence as desired. \(\square\)

Remark 1.4.4.3. In view of Proposition 1.4.4.1 and Corollary 1.4.4.2, the hypothesis that a stable \(\infty\)-category \(\mathcal{C}\) be compactly generated can be formulated entirely in terms of the homotopy category \(h\mathcal{C}\). Consequently, one can study this condition entirely in the setting of triangulated categories, without making reference to (or assuming the existence of) an underlying stable \(\infty\)-category. We refer the reader to [114] for further discussion.

Our next result provides a large class of examples of presentable stable \(\infty\)-categories.

**Proposition 1.4.4.4.** Let \(\mathcal{C}\) and \(\mathcal{D}\) be presentable \(\infty\)-categories, and suppose that \(\mathcal{D}\) is stable.

1. The \(\infty\)-category \(\text{Sp}(\mathcal{C})\) is presentable.
2. The functor \(\Omega^\infty : \text{Sp}(\mathcal{C}) \to \mathcal{C}\) admits a left adjoint \(\Sigma^\infty : \mathcal{C} \to \text{Sp}(\mathcal{C})\).
3. An exact functor \(G : \mathcal{D} \to \text{Sp}(\mathcal{C})\) admits a left adjoint if and only if \(\Omega^\infty \circ G : \mathcal{D} \to \mathcal{C}\) admits a left adjoint.

**Proof.** We first prove (1). Assume that \(\mathcal{C}\) is presentable, and let \(1\) be a final object of \(\mathcal{C}\). Then \(\mathcal{C}_*\) is equivalent to \(\mathcal{C}_{1/}\), and therefore presentable (Proposition T.5.5.3.11). The loop functor \(\Omega : \mathcal{C}_* \to \mathcal{C}_*\) admits a left adjoint \(\Sigma : \mathcal{C}_* \to \mathcal{C}_*\). Consequently, we may view the tower

\[
\ldots \xrightarrow{\Omega} \mathcal{C}_* \xrightarrow{\Omega} \mathcal{C}_*
\]

as a diagram in the \(\infty\)-category \(\mathcal{P}r^R\). Invoking Theorem T.5.5.3.18 and Remark 1.4.2.25, we deduce (1) and the following modified versions of (2) and (3):

1. The functor \(\Omega^\infty_\ast : \text{Sp}(\mathcal{C}) \to \mathcal{C}_*\) admits a left adjoint \(\Sigma^\infty : \mathcal{C}_* \to \text{Sp}(\mathcal{C})\).
2. An exact functor \(G : \mathcal{D} \to \text{Sp}(\mathcal{C})\) admits a left adjoint if and only if \(\Omega^\infty_\ast \circ G : \mathcal{D} \to \mathcal{C}_*\) admits a left adjoint.

To complete the proof, it will suffice to verify the following:

1. The forgetful functor \(\mathcal{C}_* \to \mathcal{C}\) admits a left adjoint \(\mathcal{C} \to \mathcal{C}_*\).
2. A functor \(G : \mathcal{D} \to \mathcal{C}_*\) admits a left adjoint if and only if the composition \(\mathcal{D} \xrightarrow{G} \mathcal{C}_* \to \mathcal{C}\) admits a left adjoint.
1.4. SPECTRA AND STABILIZATION

To prove (2′′) and (3′′), we recall that a functor $G$ between presentable $\infty$-categories admits a left adjoint if and only if $G$ preserves small limits and small, $\kappa$-filtered colimits, for some regular cardinal $\kappa$ (Corollary T.5.5.2.9). The desired results now follow from Propositions T.4.4.2.9 and T.1.2.13.8.  

In what follows, if $\mathcal{C}$ and $\mathcal{D}$ are presentable $\infty$-categories, we let $\text{Fun}^L(\mathcal{C}, \mathcal{D})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{D})$ spanned by those functors which admit right adjoints, and $\text{Fun}^R(\mathcal{C}, \mathcal{D})$ the full subcategory spanned by those functors which admit left adjoints.

**Corollary 1.4.4.5.** Let $\mathcal{C}$ and $\mathcal{D}$ be presentable $\infty$-categories, and suppose that $\mathcal{D}$ is stable. Then composition with $\Sigma^\infty_{+}$: $\mathcal{C} \to \text{Sp}(\mathcal{C})$ induces an equivalence $\text{Fun}^L(\text{Sp}(\mathcal{C}), \mathcal{D}) \to \text{Fun}^L(\mathcal{C}, \mathcal{D})$.

**Proof.** This is equivalent to the assertion that composition with $\Omega^\infty$ induces an equivalence $\text{Fun}^R(\mathcal{D}, \text{Sp}(\mathcal{C})) \to \text{Fun}^R(\mathcal{D}, \mathcal{C})$, which follows from Propositions 1.4.2.22 and 1.4.4.4.

Using Corollary 1.4.4.5, we obtain another characterization of the $\infty$-category of spectra. Let $S \in \text{Sp}$ denote the image under $\Sigma^\infty_{+}$: $\ast \to \text{Sp}$ of the final object $\ast \in S$. We will refer to $S$ as the sphere spectrum.

**Corollary 1.4.4.6.** Let $\mathcal{D}$ be a presentable stable $\infty$-category. Then evaluation on the sphere spectrum induces an equivalence of $\infty$-categories $\theta : \text{Fun}^L(\text{Sp}, \mathcal{D}) \to \mathcal{D}$.

In other words, we may regard the $\infty$-category $\text{Sp}$ as the stable $\infty$-category which is freely generated, under colimits, by a single object.

**Proof.** We can factor the evaluation map $\theta$ as a composition $\text{Fun}^L(\text{Sp}(S), \mathcal{D}) \overset{\theta'}{\to} \text{Fun}^L(S, \mathcal{D}) \overset{\theta''}{\to} \mathcal{D}$ where $\theta'$ is given by composition with $\Sigma^\infty_{+}$ and $\theta''$ by evaluation at the final object of $S$. We now observe that $\theta'$ and $\theta''$ are both equivalences of $\infty$-categories (Corollary 1.4.4.5 and Theorem T.5.1.5.6).

We conclude this section with yet another characterization of the class of presentable stable $\infty$-categories.

**Lemma 1.4.4.7.** Let $\mathcal{C}$ be a stable $\infty$-category, and let $\mathcal{C}' \subseteq \mathcal{C}$ be a localization of $\mathcal{C}$. Let $L : \mathcal{C} \to \mathcal{C}'$ be a left adjoint to the inclusion. Then $L$ is left exact if and only if $\mathcal{C}'$ is stable.

**Proof.** The “if” direction follows from Proposition 1.1.4.1, since $L$ is right exact. Conversely, suppose that $L$ is left exact. Since $\mathcal{C}'$ is a localization of $\mathcal{C}$, it is closed under finite limits. In particular, it is closed under the formation of fibers and contains a zero object of $\mathcal{C}$. To complete the proof, it will suffice to show that $\mathcal{C}'$ is stable under the formation of pushouts in $\mathcal{C}$. Choose a pushout diagram $\sigma : \Delta^1 \times \Delta^1 \to \mathcal{C}$

$$
\begin{array}{ccc}
X & \to & X' \\
\downarrow & & \downarrow \\
Y & \to & Y'
\end{array}
$$

in $\mathcal{C}$, where $X, X', Y \in \mathcal{C}'$. Proposition 1.1.3.4 implies that $\sigma$ is also a pullback square. Let $L : \mathcal{C} \to \mathcal{C}'$ be a left adjoint to the inclusion. Since $L$ is left exact, we obtain a pullback square $L(\sigma)$:

$$
\begin{array}{ccc}
LX & \to & LX' \\
\downarrow & & \downarrow \\
LY & \to & LY'
\end{array}
$$
Applying Proposition 1.1.3.4 again, we deduce that $L(\sigma)$ is a pushout square in $\mathcal{C}$. The natural transformation $\sigma \to L(\sigma)$ is an equivalence when restricted to $\mathcal{A}_X^L$, and therefore induces an equivalence $Y' \to LY'$. It follows that $Y'$ belongs to the essential image of $\mathcal{C}'$, as desired. \hfill \Box

**Lemma 1.4.4.8.** Let $\mathcal{C}$ be a stable $\infty$-category, $\mathcal{D}$ an $\infty$-category which admits finite limits, and $G : \mathcal{C} \to \text{Sp}(\mathcal{D})$ an exact functor. Suppose that $g = \Omega^\infty \circ G : \mathcal{C} \to \mathcal{D}$ is fully faithful. Then $G$ is fully faithful.

**Proof.** It will suffice to show that each of the composite maps

$$g_n : \mathcal{C} \to \text{Sp}(\mathcal{D}) \xrightarrow{\Omega_n^\infty} \mathcal{D}_n$$

is fully faithful. Since $g_n$ can be identified with $g_{n+1} \circ \Omega$, where $\Omega : \mathcal{C} \to \mathcal{C}$ denotes the loop functor, we can reduce to the case $n = 0$. Fix objects $C, C' \in \mathcal{C}$; we will show that the map $\text{Map}_{\mathcal{C}}(C, C') \to \text{Map}_{\mathcal{D}}(g_0(C), g_0(C'))$ is a homotopy equivalence. We have a homotopy fiber sequence

$$\text{Map}_{\mathcal{D}}(g_0(C), g_0(C')) \xrightarrow{g} \text{Map}_{\mathcal{D}}(g(C), g(C')) \to \text{Map}_{\mathcal{D}}(*, g(C')).$$

Here $*$ denotes a final object of $\mathcal{D}$. Since $g$ is fully faithful, it will suffice to prove that $\theta$ is a homotopy equivalence. For this, it suffices to show that $\text{Map}_{\mathcal{D}}(*, g(C'))$ is contractible. Since $g$ is left exact, this space can be identified with $\text{Map}_{\mathcal{D}}(g(*), g(C'))$, where $*$ is the final object of $\mathcal{C}$. Invoking once again our assumption that $g$ is fully faithful, we are reduced to proving that $\text{Map}_{\mathcal{C}}(*, C')$ is contractible. This follows from the assumption that $\mathcal{C}$ is pointed (since $*$ is also an initial object of $\mathcal{C}$). \hfill \Box

**Proposition 1.4.4.9.** Let $\mathcal{C}$ be an $\infty$-category. The following conditions are equivalent:

1. The $\infty$-category $\mathcal{C}$ is presentable and stable.
2. There exists a presentable, stable $\infty$-category $\mathcal{D}$ and an accessible left-exact localization $L : \mathcal{D} \to \mathcal{C}$.
3. There exists a small $\infty$-category $\mathcal{E}$ such that $\mathcal{C}$ is equivalent to an accessible left-exact localization of $\text{Fun}(\mathcal{E}, \text{Sp})$.

**Proof.** The $\infty$-category $\text{Sp}$ is stable and presentable. It follows that for every small $\infty$-category $\mathcal{E}$, the functor $\infty$-category $\text{Fun}(\mathcal{E}, \text{Sp})$ is also stable (Proposition 1.1.3.1) and presentable (Proposition T.5.5.3.6). This proves (3) $\Rightarrow$ (2). The implication (2) $\Rightarrow$ (1) follows from Lemma 1.4.4.7. We will complete the proof by showing that (1) $\Rightarrow$ (3).

Since $\mathcal{C}$ is presentable, there exists a small $\infty$-category $\mathcal{E}$ and a fully faithful embedding $g : \mathcal{C} \to \mathcal{P}(\mathcal{E})$, which admits a left adjoint (Theorem T.5.5.1.1). Propositions 1.4.2.22 and 1.4.4.4 implies that $g$ is equivalent to a composition

$$\mathcal{C} \xrightarrow{G} \text{Sp}(\mathcal{P}(\mathcal{E})) \xrightarrow{\Omega^\infty} \mathcal{P}(\mathcal{E}),$$

where the functor $G$ admits a left adjoint. Lemma 1.4.4.8 implies that $G$ is fully faithful. It follows that $\mathcal{C}$ is an (accessible) left exact localization of $\text{Sp}(\mathcal{P}(\mathcal{E}))$. We now invoke Remark 1.4.2.9 to identify $\text{Sp}(\mathcal{P}(\mathcal{E}))$ with $\text{Fun}(\mathcal{E}^{op}, \text{Sp})$. \hfill \Box

**Remark 1.4.4.10.** Proposition 1.4.4.9 can be regarded as an analogue of Giraud’s characterization of topoi as left exact localizations of presheaf categories ([56]). Other variations on this theme include the $\infty$-categorical version of Giraud’s theorem (Theorem T.6.1.0.6) and the Gabriel-Popescu theorem for abelian categories (see [111]).

If $\mathcal{C}$ is a presentable stable $\infty$-category, then it is reasonably easy to construct t-structures on $\mathcal{C}$: for any small collection of objects $\{X_\alpha\}$ of $\mathcal{C}$, there exists a t-structure generated by the objects $X_\alpha$. More precisely, we have the following result:

**Proposition 1.4.4.11.** Let $\mathcal{C}$ be a presentable stable $\infty$-category.
(1) If \( C' \subseteq C \) is a full subcategory which is presentable, closed under small colimits, and closed under extensions, then there exists a t-structure on \( C \) such that \( C' = C_{\geq 0} \).

(2) Let \( \{X_\alpha\} \) be a small collection of objects of \( C \), and let \( C' \) be the smallest full subcategory of \( C \) which contains each \( X_\alpha \) and is closed under extensions and small colimits. Then \( C' \) is presentable.

Proof. We will give the proof of (1) and defer the (somewhat technical) proof of (2) until the end of this section. Fix \( X \in C \), and let \( C'_{/X} \) denote the fiber product \( C' \times_C C'_{/X} \). Using Proposition T.5.5.3.12, we deduce that \( C'_{/X} \) is presentable, so that it admits a final object \( f : Y \to X \). It follows that composition with \( f \) induces a homotopy equivalence

\[
\text{Map}_C(Z, Y) \to \text{Map}_C(Z, X)
\]

for each \( Z \in C' \). Proposition T.5.2.7.8 implies that \( C' \) is a colocalization of \( C \). Since \( C' \) is stable under extensions, Proposition 1.2.1.16 implies the existence of a (uniquely determined) t-structure such that \( C' = C_{\geq 0} \).

**Definition 1.4.4.12.** Let \( C \) be a presentable stable \( \infty \)-category. We will say that a t-structure on \( C \) is **accessible** if the subcategory \( C_{\geq 0} \subseteq C \) is presentable.

Proposition 1.4.4.11 can be summarized as follows: any small collection of objects \( \{X_\alpha\} \) of a presentable stable \( \infty \)-category \( C \) determines an accessible t-structure on \( C \), which is minimal among t-structures such that each \( X_\alpha \) belongs to \( C_{\geq 0} \).

Definition 1.4.4.12 has a number of reformulations:

**Proposition 1.4.4.13.** Let \( C \) be a presentable stable \( \infty \)-category equipped with a t-structure. The following conditions are equivalent:

1. The \( \infty \)-category \( C_{\geq 0} \) is presentable (equivalently: the t-structure on \( C \) is accessible).
2. The \( \infty \)-category \( C_{\geq 0} \) is accessible.
3. The \( \infty \)-category \( C_{\leq 0} \) is presentable.
4. The \( \infty \)-category \( C_{\leq 0} \) is accessible.
5. The truncation functor \( \tau_{\leq 0} : C \to C \) is accessible.
6. The truncation functor \( \tau_{\geq 0} : C \to C \) is accessible.

Proof. We observe that \( C_{\geq 0} \) is stable under all colimits which exist in \( C \), and that \( C_{\leq 0} \) is a localization of \( C \). It follows that \( C_{\geq 0} \) and \( C_{\leq 0} \) admit small colimits, so that (1) \( \Leftrightarrow \) (2) and (3) \( \Leftrightarrow \) (4). We have a fiber sequence of functors

\[
\tau_{\geq 0} \Rightarrow \text{id}_C \Rightarrow \tau_{\leq -1}.
\]

The collection of accessible functors from \( C \) to itself is stable under shifts and under small colimits. Since \( \tau_{\leq 0} \simeq \text{cofib}(\alpha)[1] \) and \( \tau_{\geq 0} \simeq \text{cofib}(3)[{-1}] \), we conclude that (5) \( \Leftrightarrow \) (6). The equivalence (1) \( \Leftrightarrow \) (5) follows from Proposition T.5.5.1.2. We will complete the proof by showing that (1) \( \Leftrightarrow \) (3).

Suppose first that (1) is satisfied. Then \( C_{\geq 1} = C_{\geq 0}[1] \) is generated under colimits by a set of objects \( \{X_\alpha\} \). Let \( S \) be the collection of all morphisms \( f \) in \( C \) such that \( \tau_{\leq 0}(f) \) is an equivalence. Using Proposition 1.2.1.16, we conclude that \( S \) is generated by \( \{0 \to X_\alpha\} \) as a quasisaturated class of morphisms, and therefore also as a strongly saturated class of morphisms (Definition T.5.5.4.5). We now apply Proposition T.5.5.4.15 to conclude that \( C_{\leq 0} = S^{-1} C \) is presentable; this proves (3).

We now complete the proof by showing that (3) \( \Rightarrow \) (1). If \( C_{\leq -1} = C_{\leq 0}[-1] \) is presentable, then Proposition T.5.5.4.16 implies that \( S \) is of small generation (as a strongly saturated class of morphisms). Proposition 1.2.1.16 implies that \( S \) is generated (as a strongly saturated class) by the morphisms \( \{0 \to X_\alpha\}_{\alpha \in A} \), where \( X_\alpha \) ranges over the collection of all objects of \( C_{\geq 0} \). It follows that there is a small subcollection \( A_0 \subseteq A \)
such that $S$ is generated by the morphisms $\{0 \to X_\alpha\}_{\alpha \in A_0}$. Let $\mathcal{D}$ be the smallest full subcategory of $\mathcal{C}$ which contains the objects $\{X_\alpha\}_{\alpha \in A_0}$ and is closed under colimits and extensions. Since $C_{\geq 0}$ is closed under colimits and extensions, we have $\mathcal{D} \subseteq C_{\geq 0}$. Consequently, $C_{\leq -1}$ can be characterized as full subcategory of $\mathcal{C}$ spanned by those objects $Y \in \mathcal{C}$ such that $\operatorname{Ext}^k_{\mathcal{C}}(X, Y)$ for all $k \leq 0$ and $X \in \mathcal{D}$. Propositions 1.4.4.11 implies that $\mathcal{D}$ is the collection of nonnegative objects for some accessible t-structure on $\mathcal{C}$. Since the negative objects of this new t-structure coincide with the negative objects of the original t-structure, we conclude that $\mathcal{D} = C_{\geq 0}$, which proves (1).

We conclude this section by completing the proof of Proposition 1.4.4.11.

Proof of part (2) of Proposition 1.4.4.11. Choose a regular cardinal $\kappa$ such that every object of $X_\alpha$ is $\kappa$-compact, and let $\mathcal{C}^\kappa$ denote the full subcategory of $\mathcal{C}$ spanned by the $\kappa$-compact objects. Let $\mathcal{C}^\kappa = \mathcal{C}^{\kappa} \cap \mathcal{C}^\kappa$, and let $\mathcal{C}'$ be the smallest full subcategory of $\mathcal{C}$ which contains $\mathcal{C}^\kappa$ and is closed under small colimits. The $\kappa$-category $\mathcal{C}'$ is $\kappa$-accessible, and therefore presentable. To complete the proof, we will show that $\mathcal{C}' \subseteq \mathcal{C}''$. For this, it will suffice to show that $\mathcal{C}''$ is stable under extensions.

Let $\mathcal{D}$ be the full subcategory of $\text{Fun}(\Delta^1, \mathcal{C})$ spanned by those morphisms $f : X \to Y$ where $Y \in \mathcal{C}'$, $X \in \mathcal{C}'^\kappa[-1]$. We wish to prove that the cofiber functor $\text{cofib} : \mathcal{D} \to \mathcal{C}$ factors through $\mathcal{C}'$. Let $\mathcal{D}^\kappa$ be the full subcategory of $\mathcal{D}$ spanned by those morphisms $f : X \to Y$ where both $X$ and $Y$ are $\kappa$-compact objects of $\mathcal{C}$. By construction, $\text{cofib} | \mathcal{D}^\kappa$ factors through $\mathcal{C}'$. Since $\text{cofib} : \mathcal{D} \to \mathcal{C}$ preserves small colimits, it will suffice to show that $\mathcal{D}$ is generated (under small colimits) by $\mathcal{D}^\kappa$.

Fix an object $f : X \to Y$ in $\mathcal{D}$. To complete the proof, it will suffice to show that the canonical map $(\mathcal{D}^\kappa)^\text{op} \to \mathcal{D}$ is a colimit diagram. Since $\mathcal{D}$ is stable under colimits in $\text{Fun}(\Delta^1, \mathcal{C})$ and colimits in $\text{Fun}(\Delta^1, \mathcal{C})$ are computed pointwise (Proposition T.5.1.2.2), it will suffice to show that composition with the evaluation maps give colimit diagrams $(\mathcal{D}^\kappa)^\text{op} \to \mathcal{C}$. Lemma T.5.3.5.8 implies that the maps $(\mathcal{C}^\kappa[-1])^\text{op} \to \mathcal{C}$, $(\mathcal{C}^\kappa)^\text{op} \to \mathcal{C}$ are colimit diagrams. It will therefore suffice to show that the evaluation maps

$$(\mathcal{C}^\kappa[-1]) / X \xleftarrow{\theta} (\mathcal{D}^\kappa)^\text{op} \xrightarrow{\theta'} (\mathcal{C}^\kappa) / Y$$

are left cofinal.

We first show that $\theta$ is left cofinal. According to Theorem T.4.1.3.1, it will suffice to show that for every morphism $\alpha : X' \to X$ in $\mathcal{C}'[-1]$, where $X'$ is $\kappa$-compact, the $\infty$-category

$$\mathcal{E}_\theta : \mathcal{D}^\kappa \times (\mathcal{C}^\kappa[-1] / X) / \mathcal{E}_\theta$$

is weakly contractible. For this, it is sufficient to show that $\mathcal{E}_\theta$ is filtered (Lemma T.5.3.1.18).

We will show that $\mathcal{E}_\theta$ is $\kappa$-filtered. Let $K$ be a $\kappa$-small simplicial set, and $p : K \to \mathcal{E}_\theta$ a diagram; we will extend $p$ to a diagram $\tilde{p} : K^\circ \to \mathcal{E}_\theta$. We can identify $p$ with two pieces of data:

$(i)$ A map $p' : K^\circ \to \mathcal{C}^\kappa[-1] / X$.

$(ii)$ A map $p'' : (K \ast \{\infty\}) \times \Delta^1 \to \mathcal{C}$, with the properties that $p'' | (K \ast \{\infty\}) \times \{0\}$ can be identified with $p'$, $p'' | \{\infty\} \times \Delta^1$ can be identified with $f$, and $p'' | K \times \{1\}$ factors through $\mathcal{C}^\kappa$.

Let $\tilde{p}' : (K^\circ)^\text{op} \to \mathcal{C}^\kappa[-1] / X$ be a colimit of $p'$. To complete the proof that $\mathcal{E}_\theta$ is $\kappa$-filtered, it will suffice to show that we can find a compatible extension $\tilde{p}'' : (K^\circ \ast \{\infty\}) \times \Delta^1 \to \mathcal{C}$ with the appropriate properties. Let $L$ denote the full simplicial subset of $(K^\circ \ast \{\infty\}) \times \Delta^1$ spanned by every vertex except $(v, 1)$, where $v$ denotes the cone point of $K^\circ$. We first choose a map $q : L \to \mathcal{C}$ compatible with $\tilde{p}''$ and $\tilde{p}'$. This is equivalent to solving the lifting problem

$$\begin{array}{ccc}
\mathcal{E} / X \ar[d] & \ar[l] \\
K^\circ \ar[r] & \mathcal{C} / X,
\end{array}$$
1.4. SPECTRA AND STABILIZATION

which is possible since the vertical arrow is a trivial fibration. Let $L' = L \cap (K^p \times \Delta^1)$. Then $q$ determines a map $q_0 : L' \to C_{/Y}$. Finding the desired extension $\varphi''$ is equivalent to finding a map $\eta_0 : L'' \to C_{/Y}$, which carries the cone point into $C_{/Y}$.

Let $g : Z \to Y$ be a colimit of $q_0$ (in the $\infty$-category $C_{/Y}$). We observe that $Z$ is a $\kappa$-small colimit of $\kappa$-compact objects of $C$, and therefore $\kappa$-compact. Since $Y \in C'$, $Y$ can be written as the colimit of a $\kappa$-filtered diagram $\{Y_\alpha\}$, taking values in $C'_{/Y}$. Since $Z$ is $\kappa$-compact, the map $g$ factors through some $Y_\alpha$; it follows that there exists an extension $\eta_0$ as above, which carries the cone point to $Y_\alpha$. This completes the proof that $E_\theta$ is $\kappa$-filtered, and also the proof that $\theta$ is left cofinal.

The proof that $\theta'$ is left cofinal is similar but slightly easier: it suffices to show that for every map $Y' \to Y$ in $C'$, where $Y'$ is $\kappa$-compact, the fiber product

$$E_{\theta'} = D_{/Y} \times_{C_{/Y}} (C'_{/Y})_{Y'/Y}$$

is filtered. For this, we can either argue as above, or simply observe that $E_{\theta'}$ admits $\kappa$-small colimits. $\square$
Chapter 2

∞-Operads

Recall that a commutative monoid is a set $M$ equipped with a multiplication $M \times M \to M$ and a unit object $1 \in M$ satisfying the identities

$$1x = x \quad xy = yx \quad x(yz) = (xy)z$$

for all $x, y, z \in M$. Roughly speaking, a symmetric monoidal category is a category $\mathcal{C}$ equipped with the same type of structure: a unit object $1 \in \mathcal{C}$ and a functor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$. However, in the categorical setting, it is unnatural to require the identities displayed above to hold as equalities. For example, we do not expect $X \otimes (Y \otimes Z)$ to be equal to $(X \otimes Y) \otimes Z$. Instead, these identities should be formulated by requiring the existence of isomorphisms

$$\alpha_X : 1 \otimes X \simeq X \quad \beta_{X,Y} : X \otimes Y \simeq Y \otimes X$$

$$\gamma_{X,Y,Z} : (X \otimes Y) \otimes Z \simeq X \otimes (Y \otimes Z).$$

Moreover, these isomorphisms should be regarded as additional data, and are required to satisfy further conditions (such as naturality in the objects $X, Y,$ and $Z$). If we try to generalize this definition to higher categories, then the equations satisfied by the isomorphisms $\alpha_X, \beta_{X,Y},$ and $\gamma_{X,Y,Z}$ should themselves hold only up to isomorphism. It quickly becomes prohibitively complicated to explicitly specify all of the coherence conditions that these isomorphisms must satisfy. Consequently, to develop an $\infty$-categorical analogue of the theory of symmetric monoidal categories, it will be more convenient for us to proceed in another way.

We begin by considering an example of a symmetric monoidal category. Let $\mathcal{C}$ be the category of complex vector spaces, with monoidal structure given by tensor products of vector spaces. Given a pair of vector spaces $U$ and $V$, the tensor product $U \otimes V$ is characterized by the requirement that $\text{Hom}_\mathcal{C}(U \otimes V, W)$ can be identified with the set of bilinear maps $U \times V \to W$. In fact, this property really only determines $U \otimes V$ up to canonical isomorphism: in order to build an actual tensor product functor, we need to choose some particular construction of $U \otimes V$. Because this requires making certain decisions in an ad-hoc manner, it is unrealistic to expect an equality of vector spaces $U \otimes (V \otimes W) = (U \otimes V) \otimes W$. However, the existence of a canonical isomorphism between $U \otimes (V \otimes W)$ and $(U \otimes V) \otimes W$ is easily explained: linear maps from either into a fourth vector space $X$ can be identified with trilinear maps $U \times V \times W \to X$.

The above example suggests that we might reformulate the definition of a symmetric monoidal category as follows. Rather than give a bifunctor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$, we instead specify, for each $n$-tuple $(C_1, \ldots, C_n)$ of objects of $\mathcal{C}$ and each $D \in \mathcal{C}$, the collection of morphisms $C_1 \otimes \ldots \otimes C_n \to D$. Of course, we also need to specify how such morphisms are to be composed. The relevant data can be encoded in a new category, which we will denote by $\mathcal{C}^{\otimes}$.

Construction 2.0.0.1. Let $(\mathcal{C}, \otimes)$ be a symmetric monoidal category. We define a new category $\mathcal{C}^{\otimes}$ as follows:

(i) An object of $\mathcal{C}^{\otimes}$ is a finite (possibly empty) sequence of objects of $\mathcal{C}$, which we will denote by $[C_1, \ldots, C_n]$. 

135
(ii) A morphism from \([C_1, \ldots, C_n]\) to \([C'_1, \ldots, C'_m]\) in \(\mathcal{C}^{\otimes}\) consists of a subset \(S \subseteq \{1, \ldots, n\}\), a map of finite sets \(\alpha : S \to \{1, \ldots, m\}\), and a collection of morphisms \(\{f_j : \bigotimes_{\alpha(i)=j} C_i \to C'_j\}_{1 \leq j \leq m}\) in the category \(\mathcal{C}\). (Here the tensor product \(\bigotimes_{\alpha(i)=j} C_i\) is well-defined up to canonical isomorphism, since \(\mathcal{C}\) is a symmetric monoidal category.)

(iii) Suppose we are given morphisms \(f : [C_1, \ldots, C_n] \to [C'_1, \ldots, C'_m]\) and \(g : [C'_1, \ldots, C'_m] \to [C''_1, \ldots, C''_l]\) in \(\mathcal{C}^{\otimes}\), determining subsets \(S \subseteq \{1, \ldots, n\}\) and \(T \subseteq \{1, \ldots, m\}\) together with maps \(\alpha : S \to \{1, \ldots, m\}\) and \(\beta : T \to \{1, \ldots, l\}\). The composition \(g \circ f\) is given by the subset \(U = \alpha^{-1} T \subseteq \{1, \ldots, n\}\), the composite map \(\beta \circ \alpha : U \to \{1, \ldots, l\}\), and the maps

\[
\bigotimes_{(\beta \circ \alpha)(i)=k} C_i \simeq \bigotimes_{\beta(j)=k} \bigotimes_{\alpha(i)=j} C_i \to \bigotimes_{\beta(j)=k} C'_j \to C''_k
\]

for \(1 \leq k \leq l\).

To analyze this construction, we begin by recalling the definition of Segal’s category \(\Fin_*\) of pointed finite sets:

**Notation 2.0.0.2.** For any finite set \(I\), let \(I_*\) denote the set \(I \amalg \{\ast\}\) obtained from \(I\) by adjoining a new element \(\ast\). For each \(n \geq 0\), we let \(\langle n \rangle\) denote the set \(\{1, 2, \ldots, n-1, n\}\) and \(\langle n \rangle^0 = \{1, 2, \ldots, n\}\) the pointed set obtained by adjoining a disjoint base point \(\ast\) to \(\langle n \rangle\). We define a category \(\Fin_*\) as follows:

1. The objects of \(\Fin_*\) are the sets \(\langle n \rangle\), where \(n \geq 0\).

2. Given a pair of objects \(\langle m \rangle, \langle n \rangle \in \Fin_*\), a morphism from \(\langle m \rangle\) to \(\langle n \rangle\) in \(\Fin_*\) is a map \(\alpha : \langle m \rangle \to \langle n \rangle\) such that \(\alpha(\ast) = \ast\).

For every pair of integers \(1 \leq i \leq n\), we let \(\rho^i : \langle n \rangle \to \langle 1 \rangle\) denote the morphism given by the formula

\[
\rho^i(j) = \begin{cases} 1 & \text{if } i = j \\ \ast & \text{otherwise.} \end{cases}
\]

**Remark 2.0.0.3.** The category \(\Fin_*\) is equivalent to the category of all finite sets equipped with a distinguished point \(\ast\). We will often invoke this equivalence implicitly, using the following device. Let \(I\) be a finite linearly ordered set. Then there is a canonical bijection \(\alpha : I_* \simeq \langle n \rangle^0\), where \(n\) is the cardinality of \(I\); the bijection \(\alpha\) is determined uniquely by the requirement that the restriction of \(\alpha\) determines an order-preserving bijection of \(I\) with \(\langle n \rangle^0\). We will generally identify \(I_*\) with the object \(\langle n \rangle \in \Fin_*\) via this isomorphism.

**Remark 2.0.0.4.** If \(\alpha : \langle n \rangle \to \langle m \rangle\) is a morphism in \(\Fin_*\), it is convenient to think of \(\alpha\) as a *partially defined* map from \(\langle n \rangle^0\) to \(\langle m \rangle^0\): namely, \(\alpha\) is given by specifying a subset \(S = \alpha^{-1} \langle m \rangle^0 \subseteq \langle n \rangle^0\) together with a map \(S \to \langle m \rangle^0\).

For every symmetric monoidal category \(\mathcal{C}\), the category \(\mathcal{C}^{\otimes}\) of Construction 2.0.0.1 comes equipped with a forgetful functor \(\mathcal{C}^{\otimes} \to \Fin_*\), which carries an object \([C_1, \ldots, C_n]\) to the pointed finite set \(\langle n \rangle\).

**Remark 2.0.0.5.** Let \(\mathcal{C}_0\) be the category \([0]\), containing a unique object and a unique morphism. Then \(\mathcal{C}_0\) admits a unique symmetric monoidal structure. Moreover, the forgetful functor \(\mathcal{C}_0^{\otimes} \to \Fin_*\) described above is an isomorphism of categories. In other words, we may view \(\Fin_*\) as obtained by applying Construction 2.0.0.1 in the simplest possible example. Moreover, for any symmetric monoidal category \(\mathcal{C}\), the forgetful functor \(\mathcal{C}^{\otimes} \to \Fin_*\) can be viewed as obtained from the (unique) symmetric monoidal functor \(\mathcal{C} \to \mathcal{C}_0\) by means of the functoriality implicit in Construction 2.0.0.1.

For any symmetric monoidal category \(\mathcal{C}\), the forgetful functor \(\mathcal{C}^{\otimes} \to \Fin_*\) enjoys two special features:
(M1) The functor \( p \) is an \emph{op-fibration of categories}. In other words, for every object \([C_1, \ldots, C_n] \in \mathcal{C}^\otimes\) and every morphism \( f : \langle n \rangle \to \langle m \rangle \) in \( \text{Fin}_* \), there exists a morphism \( \tilde{f} : [C_1, \ldots, C_n] \to [C'_1, \ldots, C'_m] \) which covers \( f \), and is universal in the sense that composition with \( \tilde{f} \) induces a bijection

\[
\text{Hom}_{\mathcal{C}^\otimes}([C'_1, \ldots, C'_m], [C''_1, \ldots, C''_n]) \cong \text{Hom}_{\mathcal{C}^\otimes}([C_1, \ldots, C_n], [C''_1, \ldots, C''_n])
\]

for every object \([C''_1, \ldots, C''_n] \in \mathcal{C}^\otimes\). To achieve this, it suffices to choose a morphism \( \tilde{f} \) which determines a functor \( \rho \) over the object \( \langle n \rangle \in \text{Fin}_* \). It follows that there is a canonical isomorphism between the functors

\[
\text{Hom}_{\mathcal{C}^\otimes}([C_1, \ldots, C_n], [C'_1, \ldots, C'_m]) \times \text{Hom}_{\text{Fin}_*}([\langle n \rangle, \langle l \rangle]) \cong \text{Hom}_{\text{Fin}_*}([\langle m \rangle, \langle l \rangle])
\]

Remark 2.0.0.6. It follows from Condition (M1) that every morphism \( \alpha : \langle m \rangle \to \langle n \rangle \) in \( \text{Fin}_* \) induces a functor between the fibers \( \mathcal{C}^\otimes_{\langle m \rangle} \to \mathcal{C}^\otimes_{\langle n \rangle} \), which is well-defined up to canonical isomorphism.

(M2) Let \( \mathcal{C}^\otimes_{\langle n \rangle} \) denote the fiber of \( p \) over the object \( \langle n \rangle \in \text{Fin}_* \). Then \( \mathcal{C}^\otimes_{\langle n \rangle} \) is equivalent to \( \mathcal{C} \). More generally, \( \mathcal{C}^\otimes_{\langle 1 \rangle} \) is equivalent to an \( n \)-fold product of copies of \( \mathcal{C} \). This equivalence is induced by the functors associated to the maps \( \{\rho^i : \langle n \rangle \to \langle 1 \rangle\}_{1 \leq i \leq n} \) in \( \text{Fin}_* \).

We now observe that the symmetric monoidal structure on a category \( \mathcal{C} \) is determined, up to symmetric monoidal equivalence, by the category \( \mathcal{C}^\otimes \) together with its forgetful functor \( \mathcal{C}^\otimes \to \text{Fin}_* \). More precisely, suppose we are given a functor \( p : \mathcal{D} \to \text{Fin}_* \) satisfying conditions (M1) and (M2), and let \( \mathcal{C} \) denote the fiber \( \mathcal{D}_{\langle 1 \rangle} \). Then:

(a) Condition (M2) implies that \( \mathcal{D}_{\langle 0 \rangle} \) has a single object, up to equivalence. The unique morphism \( \langle 0 \rangle \to \langle 1 \rangle \) in \( \text{Fin}_* \) determines a functor \( \mathcal{D}_{\langle 0 \rangle} \to \mathcal{D}_{\langle 1 \rangle} = \mathcal{C} \), which we can identify with an object \( 1 \in \mathcal{C} \).

(b) Let \( \alpha : \langle 2 \rangle \to \langle 1 \rangle \) be the morphism given by

\[
\alpha(1) = \alpha(2) = 1 \quad \alpha(*) = *.
\]

By virtue of (M1), the functors \( \alpha \), \( \rho^1 \), and \( \rho^2 \) determine functors

\[
\mathcal{C} \times \mathcal{C} = \mathcal{D}_{\langle 1 \rangle} \times \mathcal{D}_{\langle 1 \rangle} \overset{\rho^1 \times \rho^2}{\longrightarrow} \mathcal{D}_{\langle 2 \rangle} \cong \mathcal{D}_{\langle 1 \rangle} = \mathcal{C}.
\]

Condition (M2) guarantees that the map on the left is an equivalence of categories, so that we obtain a functor \( \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) (well-defined up to canonical isomorphism), which we will denote by \( \otimes \).

(c) Let \( \sigma : \langle 2 \rangle \to \langle 2 \rangle \) denote the automorphism which exchanges the elements \( 1, 2 \in \langle 2 \rangle \). Then \( \alpha \circ \sigma = \alpha \), while \( \rho^1 \circ \sigma = \rho^2 \circ \sigma \). It follows that there is a canonical isomorphism between the functors \( (X, Y) \mapsto X \otimes Y \) and \( (X, Y) \mapsto Y \otimes X \).

(d) For \( 1 \leq i < n \), let \( \tau^i_{\langle n \rangle} : \langle n \rangle \to \langle n - 1 \rangle \) denote the map given by the formula

\[
\tau^i_{\langle n \rangle}(j) = \begin{cases} j & \text{if } 1 \leq j \leq i \\ j - 1 & \text{if } i < j \leq n \\ * & \text{if } j = * \end{cases}
\]

The commutative diagram

\[
\begin{array}{ccc}
\langle 3 \rangle & \xrightarrow{\tau^3_{\langle 2 \rangle}} & \langle 2 \rangle \\
\downarrow & & \downarrow \\
\langle 2 \rangle & \xrightarrow{\tau^2_{\langle 1 \rangle}} & \langle 1 \rangle \\
\end{array}
\]
in $\mathcal{F}in_*$ determines a diagram of categories and functors (which commutes up to canonical isomorphism):

\[
\begin{array}{ccc}
D_{(3)} & \rightarrow & D_{(2)} \\
\downarrow & & \downarrow \\
D_{(2)} & \rightarrow & D_{(1)} \\
\end{array}
\]

Combining this with the equivalences $D_{(n)} \simeq \mathcal{C}^n$, we obtain a functorial isomorphism

\[
\gamma_{A,B,C} : (A \otimes B) \otimes C \simeq A \otimes (B \otimes C).
\]

A similar argument can be used to construct canonical isomorphisms

\[
1 \otimes X \simeq X \simeq X \otimes 1.
\]

It is not difficult to see that (a), (b), (c), and (d) endow $\mathcal{C}$ with the structure of a monoidal category. For example, MacLane’s pentagon axiom asserts that the diagram

\[
\begin{array}{ccc}
((A \otimes B) \otimes C) \otimes D & \rightarrow & (A \otimes B) \otimes (C \otimes D) \\
\downarrow_{\eta_{A,B,C,D \otimes \text{id}_D}} & & \downarrow_{\eta_{A,B,C,D}} \\
A \otimes ((B \otimes C) \otimes D) & \rightarrow & A \otimes (B \otimes (C \otimes D)) \\
\end{array}
\]

is commutative. This follows from the fact that all five expressions can be canonically identified with the image of $(A, B, C, D)$ under the composite functor $\mathcal{C}^4 \simeq D_{(4)} \rightarrow D_{(1)} \simeq \mathcal{C}$, where the middle map is induced by a map $\alpha : (4) \rightarrow (1)$ in $\mathcal{F}in_*$, characterized by the requirement that $\alpha^{-1}\{1\} = (4)^\circ$. In the case where $D = \mathcal{C}^\otimes$ is given by Construction 2.0.0.1, it is easy to see that the data provided by (a) through (d) recovers the original symmetric monoidal structure on $\mathcal{C}$ (up to canonical isomorphism). Conversely, an arbitrary functor $D \rightarrow \mathcal{F}in_*$ satisfying $(M1)$ and $(M2)$ determines a symmetric monoidal structure on $\mathcal{C} = D_{(1)}$ and an equivalence $D \simeq \mathcal{C}^\otimes$. In other words, giving a symmetric monoidal category is equivalent to giving a functor $\mathcal{C}^\otimes \rightarrow \mathcal{F}in_*$ satisfying $(M1)$ and $(M2)$. However, the second definition enjoys several advantages:

- As we saw above in the case of vector spaces, it is sometimes easier to specify the category $\mathcal{C}^\otimes$ than to specify the bifunctor $\otimes$, in the sense that it requires fewer arbitrary choices.

- Axioms $(M1)$ and $(M2)$ concerning the functor $\mathcal{C}^\otimes \rightarrow \mathcal{F}in_*$ are a bit simpler than the usual definition of a (symmetric) monoidal category. Complicated assertions, such as the commutativity of MacLane’s pentagon, are consequences of $(M1)$ and $(M2)$.

The significance of the latter point becomes more apparent in the $\infty$-categorical setting, where we expect the MacLane pentagon to be only the first step in a hierarchy of coherence conditions of ever-increasing complexity. Fortunately, the above discussion suggests an approach which does not require us to formulate these conditions explicitly:

**Definition 2.0.0.7.** A symmetric monoidal $\infty$-category is a coCartesian fibration of simplicial sets $p : \mathcal{C}^\otimes \rightarrow N(\mathcal{F}in_*)$ with the following property:

\[ (*) \quad \text{For each } n \geq 0, \text{ the maps } \{ \rho^i : \langle n \rangle \rightarrow \langle 1 \rangle \}_{1 \leq i \leq n} \text{ induce functors } \rho^i : \mathcal{C}^\otimes_{(n)} \rightarrow \mathcal{C}^\otimes_{(1)} \text{ which determine an equivalence } \mathcal{C}^\otimes_{(n)} \simeq (\mathcal{C}^\otimes_{(1)})^n. \]
One of our main goals in this book is to show that Definition 2.0.0.7 is reasonable: that is, it provides a robust generalization of the classical theory of symmetric monoidal categories. Moreover, by relaxing the assumption that $p$ is a coCartesian fibration in Definition 2.0.0.7, one obtains a more general theory of $\infty$-operads (see Definition 2.1.1.10), which generalizes the classical theory of colored operads (or multicategories, as some authors refer to them).

Our objective in this chapter is to lay down the foundations for the study of $\infty$-operads. We begin in §2.1 by introducing the basic definitions. Roughly speaking, we can think of an $\infty$-operad $\mathcal{O}^\otimes$ as consisting of an underlying $\infty$-category $\mathcal{O}$, together with mapping spaces $\text{Mul}_{\mathcal{O}}(\{X_i\}_{i \in I}, Y)$ (for any finite set of objects $\{X_i \in \mathcal{O}\}_{i \in I}$ and any object $Y \in \mathcal{O}$) equipped with a coherently associative composition law (see Remark 2.1.1.17), which reduce to the usual mapping spaces in $\mathcal{O}$ when $I$ has a single element. An $\infty$-operad can be regarded as a kind of generalized $\infty$-category: we recover the usual theory of $\infty$-categories if we require that $\text{Mul}_{\mathcal{O}}(\{X_i\}_{i \in I}, Y)$ be empty when $I$ is of cardinality $\neq 1$ (see Proposition 2.1.4.11). Many $\infty$-categorical constructions can be generalized to the setting of $\infty$-operads: we will study a number of examples in §2.2.

In practice, it is quite common to encounter a family of symmetric monoidal $\infty$-categories which depend on some parameter. For example, to every commutative ring $A$ we can associate the symmetric monoidal category of $A$-modules, which depends functorially on $A$. In §2.3 we will axiomatize this phenomenon by introducing the definition of a generalized $\infty$-operad. This notion will be useful when we discuss $\infty$-categories of modules in §3.3 and when we consider variants on the little cubes operads of Boardman-Vogt in §5.4.

One can obtain a rich source of examples of symmetric monoidal $\infty$-categories by purely categorical considerations: if $\mathcal{C}$ is an $\infty$-category which admits finite products (coproducts), then $\mathcal{C}$ can be promoted to a symmetric monoidal $\infty$-category $\mathcal{C}^\otimes$ (with monoidal structure) in which the tensor product operation is given by the Cartesian product (coproduct). We will close this chapter with a detailed discussion of these examples (§2.4).

Remark 2.0.0.8. An alternate approach to the theory of $\infty$-operads has been proposed by Cisinski and Moerdijk, based on the formalism of dendroidal sets (see [31] and [32]). It seems overwhelmingly likely that their theory is equivalent to the one presented in this chapter. More precisely, there should be a Quillen equivalence between the category of dendroidal sets and the category $\text{Top}_{\infty}$ of $\infty$-preoperads which we describe in §2.4.

Nevertheless, the two perspectives differ somewhat at the level of technical detail. Our approach has the advantage of being phrased entirely in the language of simplicial sets, which allows us to draw heavily upon the preexisting theory of $\infty$-categories (as described in [97]) and to avoid direct contact with the combinatorics of trees (which play an essential role in the definition of a dendroidal set). However, the advantage comes at a cost: though our $\infty$-operads can be described using the relatively pedestrian language of simplicial sets, the actual simplicial sets which we need are somewhat unwieldy and tend to encode information in an inefficient way. Consequently, some of the proofs presented here are perhaps more difficult than they need to be: for example, we suspect that Theorems 3.1.2.3 and 3.4.4.3 admit much shorter proofs in the dendroidal setting.

### 2.1 Foundations

Our goal in this section is to introduce an $\infty$-categorical version of the classical theory of operads. We begin in §2.1.1 by reviewing the classical definition of a colored operad. The structure of an arbitrary colored operad $\mathcal{O}$ is completely encoded by a category which we will denote by $\mathcal{O}^\otimes$ (defined by a generalization of Construction 2.0.0.1), together with a forgetful functor from $\mathcal{O}^\otimes$ to Segal’s category $\text{Fin}_n$. Motivated by this observation, we will define an $\infty$-operad to be an $\infty$-category $\mathcal{O}^\otimes$ equipped with a map $\mathcal{O}^\otimes \to N(\text{Fin}_n)$, satisfying an appropriate set of axioms (Definition 2.1.1.10).

To any $\infty$-operad $\mathcal{O}^\otimes$ one can associate a theory of $\mathcal{O}$-monoidal $\infty$-categories: namely, one considers coCartesian fibrations $\mathcal{C}^\otimes \to \mathcal{O}^\otimes$ satisfying an appropriate analogue of condition (*) appearing in Definition 2.0.0.7. The relevant definitions will be given in §2.1.2. An important special case is obtained when we take $\mathcal{O}^\otimes$ to be the commutative $\infty$-operad: in this case, we recover the notion of symmetric monoidal $\infty$-category given in Definition 2.0.0.7. If $\mathcal{C}^\otimes$ is a symmetric monoidal $\infty$-category, then there is an associated theory...
of commutative algebra objects of $\mathcal{O}^\otimes$: these can be defined as sections of the fibration $\mathcal{O}^\otimes \to N(\operatorname{Fin}_*)$ which satisfy a mild additional condition. More generally, to any fibration of $\infty$-operads $\mathcal{O}^\otimes \to \mathcal{O}'^\otimes$, we can associate an $\infty$-category $\operatorname{Alg}_{/\mathcal{O}}(\mathcal{O})$ of $\mathcal{O}$-algebras in $\mathcal{O}$. We will give some basic definitions in §2.1.3, and undertake a much more comprehensive study in §3.

The collection of all $\infty$-operads can be organized into an $\infty$-category, where we take morphisms from an $\infty$-operad $\mathcal{O}^\otimes$ to another $\infty$-operad $\mathcal{O}'^\otimes$ to be given by $\mathcal{O}$-algebra objects of $\mathcal{O}'$. We will denote this $\infty$-category by $\operatorname{Op}_\infty$ and refer to it as the $\infty$-category of $\infty$-operads. In §2.1.4 we will illuminate the structure of $\operatorname{Op}_\infty$ by showing that it can be realized as the underlying $\infty$-category of a combinatorial simplicial model category. The construction of this model category uses a general existence result which we discuss in §B.4.

### 2.1.1 From Colored Operads to $\infty$-Operads

Our goal in this section is to introduce the definition of an $\infty$-operad (Definition 2.1.1.10), which will play a fundamental role throughout this book. We begin with a review of the classical theory of colored operads.

**Definition 2.1.1.1.** A colored operad $\mathcal{O}$ consists of the following data:

1. A collection $\{X, Y, Z, \ldots\}$ which we will refer to as the collection of objects or colors of $\mathcal{O}$. We will indicate that $X$ is an object of $\mathcal{O}$ by writing $X \in \mathcal{O}$.

2. For every finite set $I$, every $I$-indexed collection of objects $\{X_i\}_{i \in I}$ in $\mathcal{O}$, and every object $Y \in \mathcal{O}$, a set $\operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y)$, which we call the set of morphisms from $\{X_i\}_{i \in I}$ to $Y$.

3. For every map of finite sets $I \to J$ having fibers $\{I_j\}_{J_j \in J}$, every finite collection of objects $\{X_i\}_{i \in I}$, every finite collection of objects $\{Y_j\}_{j \in J}$, and every object $Z \in \mathcal{O}$, a composition map

$$\prod_{j \in J} \operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y_j) \times \operatorname{Mul}_\mathcal{O}(\{Y_j\}_{j \in J}, Z) \to \operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Z).$$

4. A collection of morphisms $\{\operatorname{id}_X \in \operatorname{Mul}_\mathcal{O}(\{X\}, X)\}_{X \in \mathcal{O}}$ which are both left and right units for the composition on $\mathcal{O}$ in the following sense: for every finite collection of objects $\{X_i\}_{i \in I}$ and every objects $Y \in \mathcal{O}$, the compositions

$$\operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y) \simeq \operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y) \times \{\operatorname{id}_Y\} \subseteq \operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y) \times \operatorname{Mul}_\mathcal{O}(\{Y\}, Y) \to \operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y)$$

$$\operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y) \simeq (\prod_{i \in I} \{\operatorname{id}_{X_i}\}) \times \operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y) \subseteq (\prod_{i \in I} \operatorname{Mul}_\mathcal{O}(\{X_i\}, X_i)) \times \operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y) \to \operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y)$$

both coincide with the identity map from $\operatorname{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y)$ to itself.

5. Composition is required to be associative in the following sense: for every sequence of maps $I \to J \to K$ of finite sets together with collections of objects $\{W_i\}_{i \in I}$, $\{X_j\}_{j \in J}$, $\{Y_k\}_{k \in K}$, and every object $Z \in \mathcal{O}$,
2.1. FOUNDATIONS

The diagram

\[
\prod_{j \in J} \text{Mul}_O(\{W_i\}_{i \in I_j}, X_j) \times \prod_{k \in K} \text{Mul}_O(\{X_j\}_{j \in I_k}, Y_k) \times \text{Mul}_O(\{Y_k\}_{k \in K}, Z)
\]

\[
\prod_{k \in K} \text{Mul}_O(\{W_i\}_{i \in I_k}, Y_k) \times \text{Mul}_O(\{Y_k\}_{k \in K}, Z) \quad \text{and} \quad \prod_{j \in J} \text{Mul}_O(\{W_i\}_{i \in I_j}, X_j) \times \text{Mul}_O(\{X_j\}_{j \in I_j}, Z)
\]

\[
\text{Mul}_O(\{W_i\}_{i \in I}, Z)
\]

is commutative.

**Remark 2.1.1.2.** Every colored operad \( O \) has an underlying category (which we will also denote by \( O \)) whose objects are the colors of \( O \) and whose morphisms are defined by the formula \( \text{Hom}_O(X, Y) = \text{Mul}_O(\{X\}, Y) \). Consequently, we can view a colored operad as a category with some additional structure: namely, the collections of “multilinear” maps \( \text{Mul}_O(\{X_i\}_{i \in I}, Y) \). Some authors choose to emphasize this analogy by using the term *multicategory* for what we refer to here as a colored operad.

**Variant 2.1.1.3.** We obtain a notion of a *simplicial colored operad* by replacing the morphism sets

\[
\text{Mul}_O(\{X_i\}_{i \in I}, Y)
\]

by simplicial sets in Definition 2.1.1.1.

**Remark 2.1.1.4.** Remark 2.1.1.2 describes a forgetful functor from the category \( \text{COp} \) of (small) colored operads to the category \( \text{Cat} \) of (small) categories. This functor has a left adjoint: every category \( C \) can be regarded as a colored operad by defining

\[
\text{Mul}_C(\{X_i\}_{1 \leq i \leq n}, Y) = \begin{cases} \text{Hom}(X_1, Y) & \text{if } n = 1 \\ \emptyset & \text{otherwise.} \end{cases}
\]

This construction exhibits \( \text{Cat} \) as a full subcategory of \( \text{COp} \): namely, the full subcategory spanned by those colored operads \( O \) for which the sets \( \text{Mul}_O(\{X_i\}_{i \in I}, Y) \) are empty unless \( I \) has exactly one element.

**Example 2.1.1.5.** Let \( C \) be a symmetric monoidal category: that is, a category equipped with a tensor product functor \( \otimes : C \times C \to C \) which is commutative and associative up to coherent isomorphism (see [99] for a careful definition). Then we can regard \( C \) as a colored operad by setting

\[
\text{Mul}_C(\{X_i\}_{i \in I}, Y) = \text{Hom}_C(\otimes_{i \in I} X_i, Y).
\]

We can recover the symmetric monoidal structure on \( C \) (up to canonical isomorphism) via Yoneda’s lemma. For example, for every pair of objects \( X, Y \in C \), the tensor product \( X \otimes Y \) is characterized up to canonical isomorphism by the fact that it corepresents the functor \( Z \mapsto \text{Mul}_C(\{X, Y\}, Z) \). It follows from this analysis that we can regard the notion of a symmetric monoidal category as a special case of the notion of a colored operad.

**Example 2.1.1.6.** An *operad* is a colored operad \( O \) having only a single color \( 1 \). For every nonnegative integer \( n \) we let \( O_n = \text{Mul}(\{1\}_{1 \leq i \leq n}, 1) \). We sometimes refer to \( O_n \) as the *set of \( n \)-ary operations* of \( O \). The structure of \( O \) as a colored operad is determined by the sets \( \{O_n\}_{n \geq 0} \) together with the actions of the symmetric groups \( \Sigma_n \) on \( O_n \) and the “substitution maps”

\[
O_m \times \left( \prod_{1 \leq i \leq m} O_{n_i} \right) \to O_{n_1 + \cdots + n_m}.
\]
Definition 2.1.1.1 is phrased in a somewhat complicated way because the notion of morphism in a colored operad $\mathcal{O}$ is asymmetrical: the domain of a morphism consists of a finite collection of object, while the codomain consists of only a single object. We can correct this asymmetry by packaging the data of a colored operad in a different way.

**Construction 2.1.1.7.** Let $\mathcal{O}$ be a colored operad. We define a category $\mathcal{O}^\otimes$ as follows:

1. The objects of $\mathcal{O}^\otimes$ are finite sequences of colors $X_1, \ldots, X_n \in \mathcal{O}$.
2. Given two sequences of objects $X_1, \ldots, X_m \in \mathcal{O}$ and $Y_1, \ldots, Y_n \in \mathcal{O}$, a morphism from $\{X_i\}_{1 \leq i \leq m}$ to $\{Y_j\}_{1 \leq j \leq n}$ is given by a map $\alpha : \langle m \rangle \to \langle n \rangle$ in $\mathcal{F}\text{in}_*$ together with a collection of morphisms $\{\phi_j \in \text{Mul}_\mathcal{O}(\{X_i\}_{i \leq \alpha^{-1}(j)}, Y_j)\}_{1 \leq j \leq n}$ in $\mathcal{O}$.
3. Composition of morphisms in $\mathcal{O}^\otimes$ is determined by the composition laws on $\mathcal{F}\text{in}_*$ and on the colored operad $\mathcal{O}$.

Let $\mathcal{O}$ be a colored operad. By construction, the category $\mathcal{O}^\otimes$ comes equipped with a forgetful functor $\pi : \mathcal{O}^\otimes \to \mathcal{F}\text{in}_*$. Using the functor $\pi$, we can reconstruct the colored operad $\mathcal{O}$ up to canonical equivalence. For example, the underlying category of $\mathcal{O}$ can be identified with the fiber $\mathcal{O}(1) = \pi^{-1}(\langle 1 \rangle)$. More generally, suppose that $n \geq 0$. For $1 \leq i \leq n$, let $\rho^i : \langle n \rangle \to \langle 1 \rangle$ be as in Notation 2.0.0.2, so that $\rho^i$ induces a functor $\rho^i : \mathcal{O}(n) \to \mathcal{O}(1) \simeq \mathcal{O}$ and these functors together determine an equivalence of categories $\mathcal{O}(n) \simeq \mathcal{O}^\otimes$. Given a finite sequence of colors $X_1, \ldots, X_n \in \mathcal{O}$, let $\vec{X}$ denote the corresponding object of $\mathcal{O}(n)$ (which is well-defined up to equivalence). For every color $Y \in \mathcal{O}$, the set $\text{Mul}_\mathcal{O}(\{X_i\}_{1 \leq i \leq n}, Y)$ can be identified with the set of morphisms $f : \vec{X} \to Y$ in $\mathcal{O}^\otimes$ such that $\pi(f) : \langle n \rangle \to \langle 1 \rangle$ satisfies $\pi(f)^{-1}(\*) = \{\*\}$. This shows that $\pi : \mathcal{O}^\otimes \to \mathcal{F}\text{in}_*$ determines the morphism sets $\text{Mul}_\mathcal{O}(\{X_i\}_{1 \leq i \leq n}, Y)$ in the colored operad $\mathcal{O}$; a more elaborate argument shows that the composition law for morphisms in the colored operad $\mathcal{O}$ can be recovered from the composition law for morphisms in the category $\mathcal{O}^\otimes$.

The above construction suggests that it is possible to give an alternate version of Definition 2.1.1.1: rather than thinking of a colored operad as a category-like structure $\mathcal{O}$ equipped with an elaborate notion of morphism, we can think of a colored operad as an ordinary category $\mathcal{O}^\otimes$ equipped with a forgetful functor $\pi : \mathcal{O}^\otimes \to \mathcal{F}\text{in}_*$. Of course, we do not want to consider an arbitrary functor $\pi$: we only want to consider those functors which induce equivalences $\mathcal{O}(n) \simeq (\mathcal{O}(1))^n$, so that the category $\mathcal{O} = \mathcal{O}(1)$ inherits the structure described in Definition 2.1.1.1. This is one drawback of the second approach: it requires us to formulate a somewhat complicated-looking assumption on the functor $\pi$. The virtue of the second approach is that it can be phrased entirely in the language of category theory. This allows us to generalize the theory of colored operads to the $\infty$-categorical setting. First, we need to introduce a bit of terminology.

**Definition 2.1.1.8.** We will say that a morphism $f : \langle m \rangle \to \langle n \rangle$ in $\mathcal{F}\text{in}_*$ is inert if, for each element $i \in \langle n \rangle^\circ$, the inverse image $f^{-1}\langle i \rangle$ has exactly one element.

**Remark 2.1.1.9.** Every inert morphism $f : \langle m \rangle \to \langle n \rangle$ in $\mathcal{F}\text{in}_*$ induces an injective map of sets $\alpha : \langle n \rangle^\circ \to \langle m \rangle^\circ$, characterized by the formula $f^{-1}\langle i \rangle = \{\alpha(i)\}$.

**Definition 2.1.1.10.** An $\infty$-operad is a functor $p : \mathcal{O}^\otimes \to N(\mathcal{F}\text{in}_*)$ between $\infty$-categories which satisfies the following conditions:

1. For every inert morphism $f : \langle m \rangle \to \langle n \rangle$ in $N(\mathcal{F}\text{in}_*)$ and every object $C \in \mathcal{O}^\otimes(\langle m \rangle)$, there exists a $p$-coCartesian morphism $\vec{f} : C \to C'$ in $\mathcal{O}^\otimes$ lifting $f$. In particular, $f$ induces a functor $f_! : \mathcal{O}^\otimes(\langle m \rangle) \to \mathcal{O}^\otimes(\langle n \rangle)$. 

Let $C \in \mathcal{O}(m)$ and $C' \in \mathcal{O}(n)$ be objects, let $f : \langle m \rangle \to \langle n \rangle$ be a morphism in $\mathcal{F}_{\text{in}}$, and let $\text{Map}_{\mathcal{O}}(C, C')$ be the union of those connected components of $\text{Map}_{\mathcal{O}}(C, C')$ which lie over $f \in \text{Hom}_{\mathcal{F}_{\text{in}}}(\langle m \rangle, \langle n \rangle)$. Choose $p$-coCartesian morphisms $C' \to C'_i$ lying over the inert morphisms $\rho^i : \langle n \rangle \to \langle 1 \rangle$ for $1 \leq i \leq n$. Then the induced map

$$\text{Map}_{\mathcal{O}}(C, C') \to \prod_{1 \leq i \leq n} \text{Map}_{\mathcal{O}}^{\rho^i}(C, C'_i)$$

is a homotopy equivalence.

(3) For every finite collection of objects $C_1, \ldots, C_n \in \mathcal{O}(1)$, there exists an object $C \in \mathcal{O}(n)$ and a collection of $p$-coCartesian morphisms $C \to C_i$ covering $\rho^i : \langle n \rangle \to \langle 1 \rangle$.

Remark 2.1.1.11. Definition 2.1.1.10 is really an $\infty$-categorical generalization of the notion of a colored operad, rather than that of an operad. Our choice of terminology is motivated by a desire to avoid awkward language. To obtain an $\infty$-categorical analogue of the notion of an operad, we should consider instead $\infty$-operads $\mathcal{O} \to N(\mathcal{F}_{\text{in}})$ equipped with an essentially surjective functor $\Delta^0 \to \mathcal{O}(1)$.

Remark 2.1.1.12. Let $p : \mathcal{O} \to N(\mathcal{F}_{\text{in}})$ be an $\infty$-operad. We will often abuse terminology by referring to $\mathcal{O}$ as an $\infty$-operad. We will usually denote the fiber $\mathcal{O}(1,1) \simeq p^{-1}\{1\}$ by $\mathcal{O}$. We will sometimes refer to $\mathcal{O}$ as the underlying $\infty$-category of $\mathcal{O}$.

Remark 2.1.1.13. Let $p : \mathcal{O} \to N(\mathcal{F}_{\text{in}})$ be an $\infty$-operad. Then $p$ is a categorical fibration. To prove this, we first observe that $p$ is an inner fibration (this follows from Proposition T.2.3.1.5 since $\mathcal{O} \to N(\mathcal{F}_{\text{in}})$ is the nerve of an ordinary category). In view of Corollary T.2.4.6.5, it will suffice to show that if $C \in \mathcal{O}(m)$ and $\alpha : \langle m \rangle \to \langle n \rangle$ is an isomorphism in $\mathcal{F}_{\text{in}}$, then we can lift $\alpha$ to an equivalence $\pi : C \to C'$ in $\mathcal{O}$. Since $\alpha$ is invertible, we can choose $\pi$ to be $p$-coCartesian; it then follows from Proposition T.2.4.1.5 that $\pi$ is an equivalence.

Remark 2.1.1.14. Let $p : \mathcal{O} \to N(\mathcal{F}_{\text{in}})$ be a functor between $\infty$-categories which satisfies conditions (1) and (2) of Definition 2.1.1.10. Then (3) is equivalent to the following apparently stronger condition:

(3') For each $n \geq 0$, the functors $\{\rho^i : \mathcal{O}(n) \to \mathcal{O}\}$_{$1 \leq i \leq n$} determine an equivalence of $\infty$-categories $\phi : \mathcal{O}(n) \to \mathcal{O}^n$.

It follows easily from (2) that $\phi$ is fully faithful, and condition (3) guarantees that $\phi$ is essentially surjective.

Remark 2.1.1.15. Let $p : \mathcal{O} \to N(\mathcal{F}_{\text{in}})$ be an $\infty$-operad and $\mathcal{O} = \mathcal{O}(1)$ the underlying $\infty$-category. It follows from Remark 2.1.1.14 that we have a canonical equivalence $\mathcal{O}(n) \simeq \mathcal{O}^n$. Using this equivalence, we can identify objects of $\mathcal{O}(n)$ with finite sequences $(X_1, X_2, \ldots, X_n)$ of objects of $\mathcal{O}$. We will sometimes denote the corresponding object of $\mathcal{O}$ by $X_1 \oplus X_2 \oplus \cdots \oplus X_n$ (this object is well-defined up to equivalence). More generally, given objects $X \in \mathcal{O}(m)$ and $Y \in \mathcal{O}(n)$, we let $X \oplus Y$ denote an object of $\mathcal{O}(m+n)$ corresponding to the sequence $(X_1, \ldots, X_m, Y_1, \ldots, Y_n)$. We will discuss the operation $\oplus$ more systematically in §2.2.4.

Notation 2.1.1.16. Let $\mathcal{O}$ be an $\infty$-operad, and suppose we are given a finite sequence of objects $(X_i)_{1 \leq i \leq n}$ of $\mathcal{O}$ and another object $Y \in \mathcal{O}$. We let $\text{Mul}_0((X_i)_{1 \leq i \leq n}, Y)$ denote the union of those components of $\text{Map}_{\mathcal{O}}(X_1 \oplus \cdots \oplus X_n, Y)$ which lie over the unique morphism $\beta : \langle n \rangle \to \langle 1 \rangle$ such that $\beta^{-1}\{\ast\} = \{\ast\}$. We regard $\text{Mul}_0((X_i)_{1 \leq i \leq n}, Y)$ as an object in the homotopy category $\mathcal{H}$ of spaces, which is well-defined up to canonical isomorphism.

Remark 2.1.1.17. Let $\mathcal{O}$ be an $\infty$-operad. Then we should imagine that $\mathcal{O}$ consists of an ordinary $\infty$-category $\mathcal{O}$ which comes equipped with a more elaborate notion of morphism supplied by the spaces

\section*{Chapter 2. $\infty$-Operads}

\textbf{Example 2.1.1.18.} The identity map exhibits $\text{Comm}^\otimes = N(\text{Fin}_*)$ as an $\infty$-operad, whose underlying $\infty$-category $\text{Comm}$ is isomorphic to $\Delta^0$. We will refer to this $\infty$-operad as the \textit{commutative $\infty$-operad}. When we wish to emphasize its role as an $\infty$-operad, we will sometimes denote it by $\text{Comm}^\otimes$.

\textbf{Example 2.1.1.19.} Let $\text{Fin}_{*}^{\text{inj}}$ denote the subcategory of $\text{Fin}_*$ spanned by all objects together with those morphisms $f : \langle m \rangle \to \langle n \rangle$ such that $f^{-1}\{i\}$ has at most one element for $1 \leq i \leq n$. The nerve $N(\text{Fin}_{*}^{\text{inj}})$ is an $\infty$-operad, which we will denote by $E_0^\otimes$.

\textbf{Example 2.1.1.20.} Let $\text{Triv}$ be the subcategory of $\text{Fin}_*$ whose objects are the objects of $\text{Fin}_*$, and whose morphisms are the inert morphisms in $\text{Fin}_*$. Let $\text{Triv}^\otimes = N(\text{Triv})$. Then the inclusion $\text{Triv} \subseteq \text{Fin}_*$ induces a functor $\text{Triv}^\otimes \to N(\text{Fin}_*)$ which exhibits $\text{Triv}^\otimes$ as an $\infty$-operad; we will refer to $\text{Triv}^\otimes$ as the \textit{trivial $\infty$-operad}.

\textbf{Example 2.1.1.21.} Let $\mathcal{O}$ be a colored operad in the sense of Definition 2.1.1.1, and let $\mathcal{O}^\otimes$ be the ordinary category given by Construction 2.1.1.7. Then the forgetful functor $N(\mathcal{O}^\otimes) \to N(\text{Fin}_*)$ is an $\infty$-operad. Examples 2.1.1.18, 2.1.1.19, and 2.1.1.20 all arise as special cases of this construction.

\textbf{Notation 2.1.1.22.} Example 2.1.1.21 admits a generalization to \textit{simplicial} colored operads. If $\mathcal{O}$ is a simplicial colored operad \textit{(see Variation 2.1.1.3 on Definition 2.1.1.1)}, we let $\mathcal{O}^\otimes$ denote the simplicial category given by Construction 2.1.1.7:

(i) The objects of $\mathcal{O}^\otimes$ are pairs $(\langle n \rangle, (C_1, \ldots, C_n))$, where $\langle n \rangle \in \text{Fin}_*$ and $C_1, \ldots, C_n$ are colors of $\mathcal{O}$.

(ii) Given a pair of objects $C = ((m), (C_1, \ldots, C_m))$ to $C' = ((n), (C'_1, \ldots, C'_n))$ in $\mathcal{O}^\otimes$, the simplicial set $\text{Map}_{\mathcal{O}^\otimes}(C, C')$ is defined to be

\[ \prod_{\alpha : (m) \to \langle n \rangle} \prod_{1 \leq j \leq n} \text{Mul}_\mathcal{O}(\{C_i\}_{\alpha(i) = j}, C'_j). \]

(iii) Composition in $\mathcal{O}^\otimes$ is defined in the obvious way.

\textbf{Definition 2.1.1.23.} Let $\mathcal{O}$ be a simplicial colored operad. We will denote the simplicial nerve of the category $\mathcal{O}^\otimes$ by $N^\otimes(\mathcal{O})$; we will refer to $N^\otimes(\mathcal{O})$ as the \textit{operadic nerve of $\mathcal{O}$}.

\textbf{Remark 2.1.1.24.} Let $\mathcal{O}$ be a simplicial colored operad. Then there is an evident forgetful functor from $\mathcal{O}^\otimes$ to the ordinary category $\text{Fin}_*$ (regarded as a simplicial category). This forgetful functor induces a canonical map $N^\otimes(\mathcal{O}) \to N(\text{Fin}_*)$. We may therefore regard $N^\otimes$ as a functor from the category $\text{MCat}_\Delta$ of simplicial colored operads to the category $(\text{Set}_\Delta)/_N(\text{Fin}_*)$.

\textbf{Remark 2.1.1.25.} Let $\mathcal{O}$ be a simplicial colored operad. The fiber product $N^\otimes(\mathcal{O}) \times_{N(\text{Fin}_*)} \{(1)\}$ is canonically isomorphic to the nerve of the simplicial category underlying $\mathcal{O}$; we will denote this simplicial set by $N(\mathcal{O})$.

\textbf{Definition 2.1.1.26.} We will say that a simplicial colored operad $\mathcal{O}$ is \textit{fibrant} if each of the simplicial sets $\text{Mul}_\mathcal{O}(\{X_i\}_{i \in I}, Y)$ is fibrant.

\textbf{Proposition 2.1.1.27.} Let $\mathcal{O}$ be a fibrant simplicial colored operad. Then the operadic nerve $N^\otimes(\mathcal{O})$ is an $\infty$-operad.
Proof. If $\mathcal{O}$ is a fibrant simplicial colored operad, then $\mathcal{O}^\otimes$ is a fibrant simplicial category so that $N^\otimes(\mathcal{O})$ is an $\infty$-category. Let $C = (\langle m \rangle, (C_1, \ldots, C_m))$ be an object of $N^\otimes(\mathcal{O})$ and let $\alpha : \langle m \rangle \to \langle n \rangle$ be an inert morphism in $\Fin_*$. Then we have a canonical map $C \to C' = (\langle n \rangle, (C_{\alpha^{-1}(1)}, \ldots, C_{\alpha^{-1}(n)}))$ in $\mathcal{O}^\otimes$, which we can identify with an edge $\pi$ of $N^\otimes(\mathcal{O})$ lying over $\alpha$. Using Proposition T.2.4.1.10, we deduce that $\pi$ is $p$-coCartesian, where $p : N^\otimes(\mathcal{O}) \to N(\Fin_*)$.

As a special case, we observe that there are $p$-coCartesian morphisms $\pi_{i,\langle m \rangle} : C \to (\langle 1 \rangle, C_1)$ covering $\rho^i : C \to C_i$ for $1 \leq i \leq m$. To prove that $N^\otimes(\mathcal{O})$ is an $\infty$-operad, we must show that these maps determine a $p$-limit diagram $(\langle m \rangle)^{\otimes^q} \to N^\otimes(\mathcal{O})$. Unwinding the definitions, we must show that for every object $D = (\langle n \rangle, (D_1, \ldots, D_n))$ and every morphism $\beta : \langle n \rangle \to \langle m \rangle$, the canonical map

$$\text{Map}^\beta_{\mathcal{O}^\otimes}(D, C) \to \prod_{1 \leq i \leq m} \text{Map}^{\rho^i \circ \beta}_{\mathcal{O}^\otimes}(D, (\langle 1 \rangle, C_i))$$

is a homotopy equivalence; here $\text{Map}^\beta_{\mathcal{O}^\otimes}(D, C)$ denotes the inverse image of $\{\beta\}$ in $\text{Map}_{\mathcal{O}^\otimes}(D, C)$ and $\text{Map}^{\rho^i \circ \beta}_{\mathcal{O}^\otimes}(D, (\langle 1 \rangle, C_i))$ the inverse image of $\{\rho^i \circ \beta\}$ in $\text{Map}_{\mathcal{O}^\otimes}(D, (\langle 1 \rangle, C_i))$. We now observe that this map is an isomorphism of simplicial sets.

To complete the proof that $N^\otimes(\mathcal{O})$ is an $\infty$-operad, it suffices to show that for each $m \geq 0$ the functors $\rho^i$ associated to $p$ induces an essentially surjective map

$$N^\otimes(\mathcal{O}) \times_{N(\Fin_*)} \{\langle m \rangle\} \to \prod_{1 \leq i \leq m} N(\mathcal{O}).$$

In fact, $N^\otimes(\mathcal{O}) \times_{N(\Fin_*)} \{\langle m \rangle\}$ is canonically isomorphic with $N(\mathcal{O})^m$ and this isomorphism identifies the above map with the identity. \qed

### 2.1.2 Maps of $\infty$-Operads

In order to make effective use of the theory of $\infty$-operads, we must understand them not only in isolation but also in relation to one another. To this end, we will introduce the notion of $\infty$-operad fibration (Definition 2.1.2.10). We begin with the more general notion of an $\infty$-operad map, which we will study in more detail in §2.1.3.

We begin with a brief digression on the structure of morphisms in an $\infty$-operad. According to Definition 2.1.1.8, a morphism $\gamma : \langle m \rangle \to \langle n \rangle$ in $\Fin_*$ is inert if exhibits $\langle n \rangle$ as the quotient of $\langle m \rangle$ obtained by identifying a subset of $\langle m \rangle^\circ$ with the base point $\ast$. In this case, $\gamma^{-1}$ determines an injective map from $\langle n \rangle^\circ$ to $\langle m \rangle^\circ$. By design, for any $\infty$-operad $\mathcal{O}^\otimes$, the morphism $\gamma$ induces a functor $\gamma : \mathcal{O}_{\langle \alpha \rangle}^\otimes \to \mathcal{O}_{\langle \gamma \rangle}^\otimes$. This functor can be identified with the projection map $\mathcal{O}^\otimes \to \mathcal{O}^\circ$ determined by $\gamma^{-1}$. Our choice of terminology is intended to emphasize the role of $\gamma$ as a forgetful functor, which is not really encoding the essential structure of $\mathcal{O}^\otimes$. We now introduce a class of morphisms which lies at the other extreme:

**Definition 2.1.2.1.** A morphism $f : \langle m \rangle \to \langle n \rangle$ in $\Fin_*$ is active if $f^{-1}\{\ast\} = \{\ast\}$.

**Remark 2.1.2.2.** Every morphism $f$ in $\Fin_*$ admits a factorization $f = f' \circ f''$, where $f''$ is inert and $f'$ is active; moreover, this factorization is unique up to (unique) isomorphism. In other words, the collections of inert and active morphisms determine a factorization system on $\Fin_*$.

The classes of active and inert morphisms determine a factorization system on the category $\Fin_*$ which induces an analogous factorization system on any $\infty$-operad $\mathcal{O}^\otimes$.

**Definition 2.1.2.3.** Let $p : \mathcal{O}^\otimes \to N(\Fin_*)$ be an $\infty$-operad. We will say that a morphism $f$ in $\mathcal{O}^\otimes$ is inert if $p(f)$ is inert and $f$ is $p$-coCartesian. We will say that a morphism $f$ in $\mathcal{O}^\otimes$ is active if $p(f)$ is active.

**Proposition 2.1.2.4.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad. Then the collections of active and inert morphisms determine a factorization system on $\mathcal{O}^\otimes$. 
Proposition 2.1.2.4 is an immediate consequence of Remark 2.1.2.2 together with the following general assertion:

**Proposition 2.1.2.5.** Let \( p : \mathcal{C} \rightarrow \mathcal{D} \) be an inner fibration of \( \infty \)-categories. Suppose that \( \mathcal{D} \) admits a factorization system \((S_L, S_R)\) satisfying the following condition:

\((\ast)\) For every object \( C \in \mathcal{C} \) and every morphism \( \alpha : p(C) \rightarrow D \) in \( \mathcal{D} \) which belongs to \( S_L \), there exists a \( p \)-coCartesian morphism \( \overline{\alpha} : C \rightarrow \mathcal{D} \) lifting \( \alpha \).

Let \( \overline{S}_L \) denote the collection of all \( p \)-coCartesian morphisms \( \overline{\alpha} \) in \( \mathcal{C} \) such that \( p(\overline{\alpha}) \in S_L \), and let \( \overline{S}_R = p^{-1}S_R \). Then \((\overline{S}_L, \overline{S}_R)\) is a factorization system on \( \mathcal{C} \).

**Proof.** We will prove that \((\overline{S}_L, \overline{S}_R)\) satisfies conditions (1) through (3) of Definition T.5.2.8.8:

1. The collections \( \overline{S}_L \) and \( \overline{S}_R \) are stable under retracts. This follows from the stability of \( S_L \) and \( S_R \) under retracts, together with the observation that the collection of \( p \)-coCartesian morphisms is stable under retracts.

2. Every morphism in \( \overline{S}_L \) is left orthogonal to every morphism in \( \overline{S}_R \). To prove this, let \( \overline{\alpha} : A \rightarrow B \) belong to \( \overline{S}_L \) and \( \overline{\beta} : X \rightarrow Y \) belong to \( \overline{S}_R \). Let \( \alpha : A \rightarrow B \) and \( \beta : X \rightarrow Y \) denote the images of \( \overline{\alpha} \) and \( \overline{\beta} \) under the functor \( p \). We wish to prove that the space \( \text{Map}_{\mathcal{C}/\mathcal{P}}(B, X) \) is contractible. Using the fact that \( \overline{\alpha} \) is \( p \)-coCartesian, we deduce that the map \( \text{Map}_{\mathcal{C}/\mathcal{P}}(B, X) \rightarrow \text{Map}_{\mathcal{D}/\mathcal{K}'}(B, X) \) is a trivial Kan fibration. The desired result now follows from the fact that \( \alpha \in S_L \) is left orthogonal to \( \beta \in S_R \).

3. Every morphism \( \overline{\alpha} : X \rightarrow Z \) admits a factorization \( \overline{\alpha} = \overline{\beta} \circ \overline{\gamma} \), where \( \overline{\gamma} \in \overline{S}_L \) and \( \overline{\beta} \in \overline{S}_R \). To prove this, let \( \alpha : X \rightarrow Z \) denote the image of \( \overline{\alpha} \) under \( p \). Using the fact that \((\overline{S}_L, \overline{S}_R)\) is a factorization system on \( \mathcal{D} \), we deduce that \( \alpha \) fits into a commutative diagram

\[
\begin{array}{ccc}
\gamma & \to & Y \\
\downarrow & & \downarrow \beta \\
X & \rightarrow & Z
\end{array}
\]

where \( \gamma \in S_L \) and \( \beta \in S_R \). Using assumption \((\ast)\), we can lift \( \gamma \) to a \( p \)-coCartesian morphism \( \overline{\gamma} \in \overline{S}_L \). Using the fact that \( \overline{\alpha} \) is \( p \)-coCartesian, we can lift the above diagram to a commutative triangle

\[
\begin{array}{ccc}
\gamma & \to & Y \\
\downarrow & & \downarrow \beta \\
X & \rightarrow & Z
\end{array}
\]

in \( \mathcal{C} \) having the desired properties.

\[\square\]

**Remark 2.1.2.6.** Let \( p : \mathcal{O}^{\otimes} \rightarrow \mathcal{N}(\text{Fin}_n) \) be an \( \infty \)-operad, and suppose we are given a collection of inert morphisms \( \{f_i : X \rightarrow X_i\}_{1 \leq i \leq m} \) in \( \mathcal{O}^{\otimes} \) covering maps \( \langle n \rangle \rightarrow \langle n_i \rangle \) in \( \mathcal{N}(\text{Fin}_n) \) which induce a bijection \( \coprod_{1 \leq i \leq m} \langle n_i \rangle^{\otimes} \rightarrow \langle n \rangle^{\otimes} \). These morphisms determine a \( p \)-limit diagram \( q : \langle (m)^{\otimes} \rangle^{\otimes} \rightarrow \mathcal{O}^{\otimes} \). To prove this, choose inert morphisms \( g_{i,j} : X_i \rightarrow X_{i,j} \) covering the maps \( \rho_j : \langle n_i \rangle \rightarrow \langle 1 \rangle \) for \( 1 \leq j \leq n_i \). Using the fact that \( \mathcal{O}^{\otimes} \) is an \( \infty \)-category, we obtain a diagram \( \overline{q} : \langle \coprod_{1 \leq i \leq m} \langle n_i \rangle^{\otimes} \rangle^{\otimes} \rightarrow \mathcal{O}^{\otimes} \). Since the inclusion \( \langle m \rangle^{\otimes} \subseteq \coprod_{1 \leq i \leq m} \langle n_i \rangle^{\otimes} \) is left cofinal, it will suffice to show that \( \overline{q} \) is a \( p \)-limit diagram. Using the assumption that \( \mathcal{O}^{\otimes} \) is an \( \infty \)-operad, we deduce that \( \overline{q}(\coprod_{1 \leq i \leq m} \langle n_i \rangle^{\otimes}) \) is a \( p \)-right Kan extension of \( \overline{q}(\langle n \rangle^{\otimes}) \). According to Lemma T.4.3.2.7, it will suffice to show that \( \overline{q}(\langle n \rangle^{\otimes}) \) is a \( p \)-limit diagram, which again follows from the assumption that \( \mathcal{O}^{\otimes} \) is an \( \infty \)-operad.
2.1. FOUNDATIONS

We are now ready to discuss a notion of map between $\infty$-operads.

**Definition 2.1.2.7.** Let $\mathcal{O}^\otimes$ and $\mathcal{O'}^\otimes$ be $\infty$-operads. An $\infty$-operad map from $\mathcal{O}^\otimes$ to $\mathcal{O'}^\otimes$ is a map of simplicial sets $f : \mathcal{O}^\otimes \rightarrow \mathcal{O'}^\otimes$ satisfying the following conditions:

1. The diagram

$$
\begin{array}{ccc}
\mathcal{O}^\otimes & \xrightarrow{f} & \mathcal{O'}^\otimes \\
\downarrow & & \downarrow \\
\mathcal{N}(\mathcal{Fin}_\ast) & \xrightarrow{N(\mathcal{Fin}_\ast)} & \mathcal{N}(\mathcal{Fin}_\ast)
\end{array}
$$

commutes.

2. The functor $f$ carries inert morphisms in $\mathcal{O}^\otimes$ to inert morphisms in $\mathcal{O'}^\otimes$.

We let $\text{Alg}_\mathcal{O}(\mathcal{O'})$ denote the full subcategory of $\text{Fun}_{\mathcal{N}(\mathcal{Fin}_\ast)}(\mathcal{O}^\otimes, \mathcal{O'}^\otimes)$ spanned by the $\infty$-operad maps.

**Warning 2.1.2.8.** The notation $\text{Alg}_\mathcal{O}(\mathcal{O'})$ is somewhat abusive, since it depends on the $\infty$-operads $\mathcal{O}^\otimes$ and $\mathcal{O'}^\otimes$ (and their maps to $\mathcal{N}(\mathcal{Fin}_\ast)$) and not only on the underlying $\infty$-categories $\mathcal{O}$ and $\mathcal{O'}$.

**Remark 2.1.2.9.** Let $\mathcal{O}^\otimes$ and $\mathcal{O'}^\otimes$ be $\infty$-operads, and let $F : \mathcal{O}^\otimes \rightarrow \mathcal{O'}^\otimes$ be a functor satisfying condition (1) of Definition 2.1.2.7. Then $F$ preserves all inert morphisms if and only if it preserves inert morphisms in $\mathcal{O}^\otimes$ lying over the maps $\rho^i : \langle n \rangle \rightarrow \langle 1 \rangle$. Suppose that $X \rightarrow Y$ is an inert morphism in $\mathcal{O}^\otimes$ lying over $\beta : \langle m \rangle \rightarrow \langle n \rangle$: we wish to prove that the induced map $\beta X \rightarrow F(Y)$ is an equivalence. Since $\mathcal{O'}^\otimes$ is an $\infty$-operad, it suffices to show that the induced map $\rho^i \beta X \rightarrow \rho^i F(Y)$ is an equivalence in $\mathcal{O'}^\otimes$ for $1 \leq i \leq n$. Our hypothesis allows us to identify this with the morphism $F(\rho^i \beta X) \rightarrow F(\rho^i Y)$, which is an equivalence since $Y \simeq \beta X$.

**Definition 2.1.2.10.** We will say that a map of $\infty$-operads $q : \mathcal{C}^\otimes \rightarrow \mathcal{O}^\otimes$ is a fibration of $\infty$-operads if $q$ is a categorical fibration.

**Remark 2.1.2.11.** Let $p : \mathcal{C}^\otimes \rightarrow \mathcal{O}^\otimes$ be a fibration of $\infty$-operads, and suppose we are given a collection of inert morphisms $\{f_i : X_i \rightarrow X\}_{1 \leq i \leq m}$ in $\mathcal{C}^\otimes$ covering maps $\langle n \rangle \rightarrow \langle n_i \rangle$ in $\mathcal{Fin}_\ast$, which induce a bijection $\prod_{1 \leq i \leq m} \langle n_i \rangle^\otimes \rightarrow \langle n \rangle^\otimes$. Then these morphisms determine a $p$-limit diagram $q : \langle m \rangle^\otimes \rightarrow \mathcal{C}^\otimes$. This follows from Remark 2.1.2.6 and Proposition T.4.3.1.5.

The following result describes an important special class of $\infty$-operad fibrations:

**Proposition 2.1.2.12.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad, and let $p : \mathcal{C}^\otimes \rightarrow \mathcal{O}^\otimes$ be a coCartesian fibration. The following conditions are equivalent:

(a) The composite map $q : \mathcal{C}^\otimes \rightarrow \mathcal{O}^\otimes \rightarrow \mathcal{N}(\mathcal{Fin}_\ast)$ exhibits $\mathcal{C}^\otimes$ as an $\infty$-operad.

(b) For every object $T \simeq T_1 \oplus \cdots \oplus T_n \in \mathcal{O}^\otimes$, the inert morphisms $T \rightarrow T_i$ induce an equivalence of $\infty$-categories $\mathcal{C}^\otimes_T \rightarrow \prod_{1 \leq i \leq n} \mathcal{C}^\otimes_{T_i}$.

**Proof.** Suppose that (a) is satisfied. We first claim that $p$ preserves inert morphisms. To prove this, choose an inert morphism $f : C \rightarrow C'$ in $\mathcal{C}^\otimes$. Let $g : p(C) \rightarrow X$ be an inert morphism in $\mathcal{O}^\otimes$ lifting $q(f)$, and let $\overline{g} : C \rightarrow X$ be a $p$-coCartesian lift of $g$. It follows from Proposition T.2.4.1.3 that $\overline{g}$ is a $q$-coCartesian lift of $q(f)$ and therefore equivalent to $f$. We conclude that $p(f)$ is equivalent to $p(\overline{g}) = g$ and is therefore inert.

The above argument guarantees that for each $n \geq 0$, the maps $\{\rho^i\}_{1 \leq i \leq n}$ determine a homotopy commutative diagram

$$
\begin{array}{ccc}
\mathcal{C}^\otimes_{\langle n \rangle} & \xrightarrow{\rho^i} & \mathcal{O}^\otimes_{\langle n \rangle} \\
\downarrow & & \downarrow \\
\mathcal{C}^\otimes & \xrightarrow{\rho^i} & \mathcal{O}^\otimes
\end{array}
$$
and the assumption that $\mathcal{C}^\otimes$ and $\mathcal{O}^\otimes$ are $\infty$-operads guarantees that the vertical maps are categorical equivalences. Let $T$ be an object of $\mathcal{O}^\otimes_{(n)}$. Passing to the homotopy fibers over the vertices $T$ and $(T_i)_{1 \leq i \leq n}$ (which are equivalent to the actual fibers by virtue of Corollary T.3.3.1.4), we deduce that the canonical map $\mathcal{C}^\otimes_T \to \prod_{1 \leq i \leq n} \mathcal{C}^\otimes_{T_i}$ is an equivalence, which proves (b).

Now suppose that (b) is satisfied. We will prove that the functor $q : \mathcal{C}^\otimes \to N(\mathcal{F}\text{in}_*)$ satisfies the conditions of Definition 2.1.1.10. To prove (1), consider an object $C \in \mathcal{C}^\otimes$ and an inert morphism $\alpha : q(C) \to \langle n \rangle$ in $\mathcal{F}\text{in}_*$. Since $\mathcal{O}^\otimes \to N(\mathcal{F}\text{in}_*)$ is an $\infty$-operad, there exists an inert morphism $\tilde{\alpha} : p(C) \to X$ in $\mathcal{O}^\otimes$ lying over $\alpha$. Since $p$ is a coCartesian fibration, we can lift $\tilde{\alpha}$ to a $p$-coCartesian morphism $\tilde{\pi} : C \to X$ in $\mathcal{C}^\otimes$. Proposition T.2.4.1.3 implies that $\tilde{\pi}$ is $p$-coCartesian, which proves (1).

Now let $C \in \mathcal{O}^\otimes_{(m)}$, $C' \in \mathcal{O}^\otimes_{(n)}$, and $f : \langle m \rangle \to \langle n \rangle$ be as in condition (2) of Definition 2.1.1.10. Set $T = p(C)$, set $T' = p(C')$, choose inert morphisms $g_i : T \to T'_i$ lying over $\rho^i$ for $1 \leq i \leq n$, and choose $p$-coCartesian morphisms $\tilde{g}_i : C \to C'_i$ lying over $g_i$ for $1 \leq i \leq n$. Let $f_i = \rho^i \circ f$ for $1 \leq i \leq n$. We have a homotopy coherent diagram

$$
\begin{array}{ccc}
\text{Map}_{\mathcal{C}^\otimes}(C, C') & \longrightarrow & \prod_{1 \leq i \leq n} \text{Map}_{\mathcal{C}^\otimes}(C, C'_i) \\
\downarrow & & \downarrow \\
\text{Map}_{\mathcal{O}^\otimes}(T, T') & \longrightarrow & \prod_{1 \leq i \leq n} \text{Map}_{\mathcal{O}^\otimes}(T, T'_i).
\end{array}
$$

Since $\mathcal{O}^\otimes$ is an $\infty$-operad, the bottom horizontal map is a homotopy equivalence. Consequently, to prove that the top map is a homotopy equivalence, it will suffice to show that it induces a homotopy equivalence after passing to the homotopy fiber over any $h : T \to T'$ lying over $f$. Let $D = hC$ and let $D_i = (g_i)_*D$ for $1 \leq i \leq n$. Using the assumption that $p$ is a coCartesian fibration and Proposition T.2.4.4.2, we see that the map of homotopy fibers can be identified with

$$
\text{Map}_{\mathcal{C}^\otimes_T}(D, C) \to \prod_{1 \leq i \leq n} \text{Map}_{\mathcal{C}^\otimes_{T_i}}(D_i, C_i),
$$

which is a homotopy equivalence by virtue of assumption (b).

We now prove (3). Fix a sequence of objects $\{C_i \in \mathcal{C}^\otimes_{(1)}\}_{1 \leq i \leq n}$, and set $T_i = p(C_i)$. Since $\mathcal{O}^\otimes$ is an $\infty$-operad, we can choose an object $T \in \mathcal{O}^\otimes$ equipped with inert morphisms $f_i : T \to T_i$ lifting $\rho^i$ for $1 \leq i \leq n$. Invoking (b), we conclude that there exists an object $C$ together with $p$-coCartesian morphisms $\tilde{f}_i : C \to C_i$ lifting $f_i$. It follows from Proposition T.2.4.1.3 that each $\tilde{f}_i$ is $q$-coCartesian, so that condition (3) is satisfied and the proof is complete.

**Definition 2.1.2.13.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad. We will say that a map $p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ is a coCartesian fibration of $\infty$-operads if it satisfies the hypotheses of Proposition 2.1.2.12. In this case, we also say that $p$ exhibits $\mathcal{C}^\otimes$ as a $\mathcal{O}$-monoidal $\infty$-category.

**Remark 2.1.2.14.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad and let $p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a coCartesian fibration of $\infty$-operads. Then $p$ is a map of $\infty$-operads: this follows from the first step of the proof of Proposition 2.1.2.12. Combining this observation with Proposition T.3.3.1.7, we conclude that $p$ is a fibration of $\infty$-operads in the sense of Definition 2.1.2.10.

**Remark 2.1.2.15.** In the situation of Definition 2.1.2.13, we will generally denote the fiber product $\mathcal{C}^\otimes \times_{\mathcal{O}^\otimes} \mathcal{O}$ by $\mathcal{C}$, and abuse terminology by saying that $\mathcal{C}$ is an $\mathcal{O}$-monoidal $\infty$-category.

**Remark 2.1.2.16.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad and let $p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a coCartesian fibration of $\infty$-operads. For every object $X \in \mathcal{O}^\otimes$, we let $\mathcal{C}_X^\otimes$ denote the inverse image of $T$ under $p$. If $X \in \mathcal{O}$, we will also denote this $\infty$-category by $\mathcal{C}_X$. Note that if $X \in \mathcal{O}^\otimes_{(n)}$ corresponds to a sequence of objects $\{X_i\}_{1 \leq i \leq n}$ in $\mathcal{O}$, then we have a canonical equivalence $\mathcal{C}_X^\otimes \simeq \prod_{1 \leq i \leq n} \mathcal{C}_{X_i}$. 
Given a morphism \( f \in \text{Mul}_\mathcal{O}(\{X_i\}_{1 \leq i \leq n}, Y) \) in \( \mathcal{O} \), the coCartesian fibration \( p \) determines a functor

\[
\prod_{1 \leq i \leq n} \mathcal{E}_{X_i} \simeq \mathcal{E}_X^\otimes \to \mathcal{E}_Y
\]

which is well-defined up to equivalence; we will sometimes denote this functor by \( \otimes_f \).

**Remark 2.1.2.17.** Let \( \mathcal{O}^\otimes \) be an \( \infty \)-operad, and let \( \mathcal{E}^\otimes \to \mathcal{O}^\otimes \) be a \( \mathcal{O} \)-monoidal \( \infty \)-category. Then the underlying map \( \mathcal{E} \to \mathcal{O} \) is a coCartesian fibration of \( \infty \)-categories, which is classified by a functor \( \chi : \mathcal{O} \to \mathcal{C} \text{at}_\infty \). In other words, we can think of a \( \mathcal{O} \)-monoidal \( \infty \)-category as assigning to each color \( X \in \mathcal{O} \) an \( \infty \)-category \( \chi(X) \) of \( X \)-colored objects. We will later see that \( \chi \) can be extended to a map of \( \infty \)-operads, and that this map of \( \infty \)-operads determines \( \mathcal{E}^\otimes \) up to equivalence (Example 2.4.2.4 and Proposition 2.4.2.5).

**Example 2.1.2.18.** A symmetric monoidal \( \infty \)-category is an \( \infty \)-category \( \mathcal{C}^\otimes \) equipped with a coCartesian fibration of \( \infty \)-operads \( p : \mathcal{C}^\otimes \to N(\text{Fin}_n) \) (Definition 2.0.0.7).

**Remark 2.1.2.19.** In other words, a symmetric monoidal \( \infty \)-category is a coCartesian fibration \( p : \mathcal{C}^\otimes \to N(\text{Fin}_n) \) which induces equivalences of \( \infty \)-categories \( \mathcal{C}^\otimes_{(n)} \simeq \mathcal{C}^n \) for each \( n \geq 0 \), where \( \mathcal{C} \) denotes the \( \infty \)-category \( \mathcal{C}^\otimes_{(1)} \).

**Remark 2.1.2.20.** Let \( \mathcal{C}^\otimes \to N(\text{Fin}_n) \) be a symmetric monoidal \( \infty \)-category. We will refer to the fiber \( \mathcal{C}^\otimes_{(n)} \) as the underlying \( \infty \)-category of \( \mathcal{C}^\otimes \); it will often be denoted by \( \mathcal{C} \). We will sometimes abuse terminology by referring to \( \mathcal{C} \) as a symmetric monoidal \( \infty \)-category, or say that \( \mathcal{C}^\otimes \) determines a symmetric monoidal structure on \( \mathcal{C} \).

Using the constructions of Remark 2.1.2.16, we see that the active morphisms \( \alpha : \langle 0 \rangle \to \langle 1 \rangle \) and \( \beta : \langle 2 \rangle \to \langle 1 \rangle \) determine functors

\[
\Delta^0 \to \mathcal{C} \quad \mathcal{C} \times \mathcal{C} \to \mathcal{C},
\]

which are well-defined up to a contractible space of choice. The first of these functors determines an object of \( \mathcal{C} \) which we will denote by \( 1 \) (or sometimes \( 1_{\mathcal{C}} \) if we wish to emphasize the dependence on \( \mathcal{C} \)) and refer to as the unit object of \( \mathcal{C} \).

It is not difficult to verify that the unit object \( 1 \in \mathcal{C} \) and the tensor product \( \otimes \) on \( \mathcal{C} \) satisfy all of the usual axioms for a symmetric monoidal category up to homotopy. In particular, these operations endow the homotopy category \( \text{hC} \) with a symmetric monoidal structure.

**Example 2.1.2.21.** Let \( \mathcal{C} \) be a symmetric monoidal category (see [99]), so that we can regard \( \mathcal{C} \) as a colored operad as in Example 2.1.1.5. The \( \infty \)-operad \( N(\mathcal{C}^\otimes) \) of Example 2.1.1.21 is a symmetric monoidal \( \infty \)-category (whose underlying \( \infty \)-category is the nerve \( N(\mathcal{C}) \)).

We conclude this section with a useful criterion for detecting \( \infty \)-operad fibrations:

**Proposition 2.1.2.22.** Let \( q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a map of \( \infty \)-operads which is an inner fibration. The following conditions are equivalent:

(1) The map \( q \) is a fibration of \( \infty \)-operads.

(2) For every object \( C \in \mathcal{C}^\otimes \) and every inert morphism \( f : q(C) \to X \) in \( \mathcal{O}^\otimes \), there exists an inert morphism \( \tilde{f} : C \to X \) in \( \mathcal{C}^\otimes \) such that \( f = q(\tilde{f}) \).

Moreover, if these conditions are satisfied, then the inert morphisms of \( \mathcal{C}^\otimes \) are precisely the \( q \)-coCartesian morphisms in \( \mathcal{C}^\otimes \) whose image in \( \mathcal{O}^\otimes \) is inert.

**Proof.** According to Corollary T.2.4.6.5, condition (1) is satisfied if and only if condition (2) is satisfied whenever \( f \) is an equivalence; this proves that \( (2) \Rightarrow (1) \). For the reverse implication, suppose that \( q \) is a categorical fibration and let \( f : q(C) \to X \) be as in (2). Let \( f_0 : \langle m \rangle \to \langle n \rangle \) denote the image of \( f \) in \( N(\text{Fin}_n) \),
and let $f : C \to X'$ be an inert morphism in $\mathcal{O}^\otimes$ lifting $f_0$. Since $f$ and $q(f')$ are both inert lifts of the morphism $f_0$, we can find a 2-simplex

\[
\begin{array}{ccc}
C & \xrightarrow{\pi} & X \\
\downarrow{f} & & \downarrow{\pi} \\
\pi(C) & \xrightarrow{q} & X'
\end{array}
\]

in $\mathcal{O}^\otimes$ where $q$ is an equivalence. Since $q$ is a categorical fibration, Corollary T.2.4.6.5 guarantees that we can choose an equivalence $\pi : X' \to X$ in $\mathcal{O}^\otimes$ lifting $g$. Using the fact that $q$ is an inner fibration, we can lift the above diagram to a 2-simplex

\[
\begin{array}{ccc}
C & \xrightarrow{f} & X \\
\downarrow{\pi} & & \downarrow{\pi} \\
\pi(C) & \xrightarrow{q} & X'
\end{array}
\]

in $\mathcal{O}^\otimes$. Since $f$ is the composition of an inert morphism with an equivalence, it is an inert morphism which lifts $f$, as desired. This completes the proof of the implication (1) $\Rightarrow$ (2); the final assertion follows immediately from Proposition T.2.4.1.3 (and the assumption that $q$ preserves inert morphisms).

\textbf{2.1.3 Algebra Objects}

In this section, we will undertake a more systematic study of maps between $\infty$-operads. We begin by introducing a variation on Definition 2.1.2.7.

\textbf{Definition 2.1.3.1.} Let $p : \mathcal{E}^\otimes \to \mathcal{O}^\otimes$ be a fibration of $\infty$-operads, and suppose we are given $\infty$-operads $\alpha : \mathcal{O}'^\otimes \to \mathcal{O}^\otimes$. We let $\text{Alg}_{\mathcal{O}'^\otimes / \mathcal{O}}(\mathcal{E})$ denote the full subcategory of $\text{Fun}_{\mathcal{O}^\otimes}(\mathcal{E}^\otimes, \mathcal{O}^\otimes)$ spanned by the maps of $\infty$-operads. Equivalently, $\text{Alg}_{\mathcal{O}'^\otimes / \mathcal{O}}(\mathcal{E})$ can be described as the fiber over the vertex $\alpha$ of the categorical fibration $\text{Alg}_{\mathcal{O}}(\mathcal{E}) \to \text{Alg}_{\mathcal{O}}(\mathcal{O})$ given by composition with $p$. In the special case where $\mathcal{O}'^\otimes = \mathcal{O}^\otimes$ and $\alpha$ is the identity map, we will denote the $\infty$-category $\text{Alg}_{\mathcal{O}'^\otimes / \mathcal{O}}(\mathcal{E})$ by $\text{Alg}_{/ \mathcal{O}}(\mathcal{E})$.

In the special case where $\mathcal{O}'^\otimes = \mathcal{O}^\otimes = N(\text{Fin}_\ast)$, we will denote the $\infty$-category $\text{Alg}_{\mathcal{O}'^\otimes / \mathcal{O}}(\mathcal{E})$ as $\text{Alg}_{/ \mathcal{O}}(\mathcal{E}) = \text{Alg}_{\mathcal{O}}(\mathcal{E})$ by $\text{CAlg}(\mathcal{E})$. We will refer to $\text{CAlg}(\mathcal{E})$ as the $\infty$-category of commutative algebra objects of $\mathcal{E}$.

\textbf{Remark 2.1.3.2.} In the situation of Definition 2.1.3.1, we will sometimes abuse terminology by referring to $\text{Alg}_{\mathcal{O}'^\otimes / \mathcal{O}}(\mathcal{E})$ as the $\infty$-category of $\mathcal{O}'$-algebra objects of $\mathcal{E}$. Note that this $\infty$-category is generally not equivalent to the $\infty$-category $\text{Alg}_{\mathcal{O}'}(\mathcal{E})$ of Definition 2.1.2.7 (except in the special case $\mathcal{O}'^\otimes = N(\text{Fin}_\ast)$).

\textbf{Example 2.1.3.3.} Let $\mathcal{E}$ be a symmetric monoidal category, and let us regard $N(\mathcal{E})$ as a symmetric monoidal $\infty$-category via the construction described in Example 2.1.2.21. Then $\text{CAlg}(N(\mathcal{E}))$ can be identified with the nerve of the category of commutative algebra objects of $\mathcal{E}$: that is, objects $A \in \mathcal{E}$ equipped with a unit map $1_A \to A$ and a multiplication $A \otimes A \to A$ which is commutative, unital, and associative.

\textbf{Remark 2.1.3.4.} Let $\mathcal{O}^\otimes$ be an $\infty$-operad, let $\mathcal{E}^\otimes \to \mathcal{O}^\otimes$ be a coCartesian fibration of $\infty$-operads, and let $K$ be an arbitrary simplicial set. Then the induced map

$$
\text{Fun}(K, \mathcal{E}^\otimes) \times_{\text{Fun}(K, \mathcal{O}^\otimes)} \mathcal{O}^\otimes \to \mathcal{O}^\otimes
$$

is again a coCartesian fibration of $\infty$-operads. For every object $X \in \mathcal{O}$, we have a canonical isomorphism $\mathcal{D}_X \simeq \text{Fun}(K, \mathcal{E}_X)$, and the operations $\otimes_f$ of Remark 2.1.2.16 are computed pointwise. We have a canonical isomorphism

$$
\text{Alg}_{/ \mathcal{O}}(\mathcal{D}) \simeq \text{Fun}(K, \text{Alg}_{/ \mathcal{O}}(\mathcal{E})).
$$
Example 2.1.3.5. Let \( q : O^\otimes \to N(\text{Fin}_*) \) be an \( \infty \)-operad such that the image of \( q \) is contained in \( \text{Triv}^\otimes \subseteq N(\text{Fin}_*) \), and let \( p : C^\otimes \to O^\otimes \) be a \( O \)-monoidal \( \infty \)-category. We observe that a section \( A : O^\otimes \to C^\otimes \) of \( p \) is a \( O \)-algebra if and only if \( A \) is a \( p \)-right Kan extension of its restriction to \( O \subseteq O^\otimes \). Using Proposition T.4.3.2.15, we deduce that the restriction map \( \text{Alg}_{/O}(\mathcal{C}) \to \text{Fun}_O(O, \mathcal{C}) \) is a trivial Kan fibration. In particular, taking \( O^\otimes \) to be the trivial \( \infty \)-operad \( \text{Triv}^\otimes \), we obtain a trivial Kan fibration \( \text{Alg}_{/\text{Triv}}(\mathcal{C}) \to \mathcal{C} \).

Remark 2.1.3.6. Let \( O^\otimes \) be an \( \infty \)-operad. Since \( \text{Triv}^\otimes \) can be identified with a simplicial subset of \( N(\text{Fin}_*) \), an \( \infty \)-operad map \( p : O^\otimes \to \text{Triv}^\otimes \) is unique if it exists. If this condition is satisfied, then \( p \) is automatically a coCartesian fibration.

Now let \( O^\otimes \) be a general \( \infty \)-operad. The \( \infty \)-category \( \text{Alg}_{/\text{Triv}}(O) \) can be identified with the collection of \( \text{Triv} \)-algebras in \( \infty \)-category \( O^\otimes \times N(\text{Fin}_*) \text{Triv}^\otimes \). By virtue of Example 2.1.3.5, we deduce that evaluation at \( \langle 1 \rangle \) induces a trivial Kan fibration \( \text{Alg}_{/\text{Triv}}(O) \to O \).

Suppose that \( p : C^\otimes \to N(\text{Fin}_*) \) and \( q : D^\otimes \to N(\text{Fin}_*) \) are symmetric monoidal \( \infty \)-categories. An \( \infty \)-operad map \( F \in \text{Alg}_C(D) \) can be thought of as a functor \( F : C \to D \) which is compatible with the symmetric monoidal structures in the lax sense that we are given maps

\[
F(C) \otimes F(C') \to F(C \otimes C') \quad 1 \to F(1)
\]

which are compatible with the commutativity and associativity properties of the tensor products on \( C \) and \( D \). Our next definition singles out a special class of \( \infty \)-category maps for which the morphisms above are required to be equivalences.

Definition 2.1.3.7. Let \( O^\otimes \) be an \( \infty \)-operad, and let \( p : C^\otimes \to O^\otimes \) and \( q : D^\otimes \to O^\otimes \) be coCartesian fibrations of \( \infty \)-operads. We will say that an \( \infty \)-operad map \( f \in \text{Alg}_C(D) \) is a \( O \)-monoidal functor if it carries \( p \)-coCartesian morphisms to \( q \)-coCartesian morphisms. We let \( \text{Fun}_{O^\otimes}(C, D) \) denote the full subcategories \( \text{Fun}_{O^\otimes}(C^\otimes, D^\otimes) \) spanned by the \( O \)-monoidal functors.

In the special case where \( O^\otimes = N(\text{Fin}_*) \), we will denote \( \text{Fun}_{O^\otimes}(C, D) \) by \( \text{Fun}^O(C, D) \); we will refer to objects of \( \text{Fun}^O(C, D) \) as symmetric monoidal functors from \( O^\otimes \) to \( D^\otimes \).

Remark 2.1.3.8. Let \( F : C^\otimes \to D^\otimes \) be a \( O \)-monoidal functor between \( O \)-monoidal \( \infty \)-categories, where \( O^\otimes \) is an \( \infty \)-operad. Using Corollary T.2.4.4.4, we deduce that the following conditions are equivalent:

1. The functor \( F \) is an equivalence.
2. The underlying map of \( \infty \)-categories \( C \to D \) is an equivalence.
3. For every object \( X \in O \), the induced map of fibers \( C_X \to D_X \) is an equivalence.

The analogous statement fails if we assume only that \( F \in \text{Alg}_{/O}(D) \).

We conclude this section by considering a variant on Example 2.1.3.5, which can be used to describe algebras over the \( \infty \)-operad \( E^\otimes_0 \) of Example 2.1.1.19.

Proposition 2.1.3.9. Let \( p : O^\otimes \to E^\otimes_0 \) be a fibration of \( \infty \)-operads, and consider the map \( \Delta^1 \to E^\otimes_0 \) corresponding to the unique morphism \( \alpha : \langle 0 \rangle \to \langle 1 \rangle \) of \( \text{Fin}_* \inj \subseteq \text{Fin}_* \). Then the restriction functor

\[
\theta : \text{Alg}_{/E_0}(O) \to \text{Fun}_{E_0^\otimes}(\Delta^1, O^\otimes)
\]

is a trivial Kan fibration.

Remark 2.1.3.10. Suppose that \( C^\otimes \) is a symmetric monoidal \( \infty \)-category with unit object \( 1 \). Proposition 2.1.3.9 implies that we can identify \( \text{Alg}_{/E_0}(C) \) with the \( \infty \)-category \( C_{/A} \) consisting of maps \( 1 \to A \) in \( C \). In other words, an \( E_0 \)-algebra object of \( C \) is an object \( A \in C \) equipped with a unit map \( 1 \to A \), but no other additional structures.
We observe that a functor $F_i$ is a $p$-right Kan extension of $E_i$ spanned by those functors $F$ satisfying the following conditions:

(a) For $i \in [1]$, the morphism $F(s(i)) \to F(i)$ is an equivalence in $\Op^{\otimes}$.

(b) The restriction $F|_{\Op^{0}}$ belongs to $\Alg_{/\Op}(\Cc$).

We observe that a functor $F$ satisfies condition $(\ast)$ if and only if it is a left Kan extension of $F|_{\Op^{0}}$. Using Proposition T.4.3.2.15, we deduce that the restriction map $\phi : \Cc \to \Alg_{/\Op}(\Cc)$ is a trivial Kan fibration. Let $\theta' : \Cc \to \Alg_{/\Op}(\D, \Op^{\otimes})$ be the map given by restriction to $\D \simeq N([1])$. The map $\theta'$ can be written as a composition

$$\Alg_{/\Op}(\Op) \to \Cc \xrightarrow{\theta'} \Alg_{/\Op}(\D, \Op^{\otimes}),$$

where the first map is the section of $\phi$ given by composition with $r$ (and therefore a categorical equivalence). By a two-out-of-three argument, we are reduced to proving that $\theta'$ is a categorical equivalence.

We will show that $\theta'$ is a trivial Kan fibration. By virtue of Proposition T.4.3.2.15, it will suffice to prove the following:

(i) A functor $\Alg_{/\Op}(N(\D), \Op^{\otimes})$ belongs to $\Cc$ if and only if $F$ is a $p$-right Kan extension of $F|_{\D}$.

(ii) Every functor $F_0 \in \Alg_{/\Op}(\D, \Op^{\otimes})$ admits a $p$-right Kan extension $F \in \Alg_{/\Op}(N(\D), \Op^{\otimes})$.

To see this, fix an object $F \in \Alg_{/\Op}(N(\D), \Op^{\otimes})$ and consider an object $\langle n \rangle \in \Fin^{\leq 1}_{*}$. Let $J_0$ denote the full subcategory of $\D$ obtained by omitting the map $\langle n \rangle \to 1$ corresponding to the nonsurjective map $\langle n \rangle \to 0$ in $\Fin^{\leq 1}_{*}$, and let $J_1$ denote the full subcategory of $J_0$ obtained by omitting the unique map $\langle n \rangle \to 0$. We observe that the inclusion $N(J_0) \subseteq N(\D)$ is right cofinal and that the restriction $F|_{N(J_0)}$ is a $p$-right Kan extension of $F|_{N(\D)}$. Using Lemma T.4.3.2.7, we deduce that $F$ is a $p$-right Kan extension of $F|_{\D}$ at $\langle n \rangle$ if and only if the induced map

$$N(J_1)^n \to N(\D) \xrightarrow{F} \Op^{\otimes}$$

is a $p$-limit diagram. Combining this with the observation that $J_1$ is a discrete category (whose objects can be identified with the elements of $\langle n \rangle$), we obtain the following version of (i):

(i') A functor $F \in \Alg_{/\Op}(N(\D), \Op^{\otimes})$ is a $p$-right Kan extension of $F|_{\D}$ if and only if, for every nonnegative integer $n$, the maps $F(\rho^n) : F(\langle n \rangle) \to F(1)$ exhibit $F(\langle n \rangle)$ as a $p$-product of the objects $\{F(1)\}_{1 \leq i \leq n}$.

Since $\Op^{\otimes}$ is an $\infty$-operad, condition (i') is equivalent to the requirement that each of the maps $F(\rho^n) : F(\langle n \rangle) \to F(1)$ is inert.

We now prove (i). Suppose first that $F$ is a $p$-right Kan extension of $F|_{\D}$. We will show that $F \in \Cc$. We first show that the map $F(s(i)) \to F(i)$ is an equivalence in $\Op^{\otimes}$ for $i \in [1]$. If $i = 0$ this is clear (the $\infty$-category $\Op^{\otimes}(0)$ is a contractible Kan complex, so every morphism in $\Op^{\otimes}(0)$ is an equivalence). If $i = 1$, we
apply condition (i') in the case $n = 1$. Using this observation, we see that the condition of (i') is equivalent to the requirement that the maps $\rho^i : \langle n \rangle \to \langle 1 \rangle$ induce inert morphisms $F(\langle n \rangle) \to F(\langle 1 \rangle)$ for $1 \leq i \leq n$, so that $F|E_0^S \in \text{Alg}_{/S}(0)$. This proves that $F \in \mathcal{C}$ as desired.

Conversely, suppose that $F \in \mathcal{C}$. If $1 \leq i \leq n$, then the map $F(\rho^i) : F(\langle n \rangle) \to F(\langle 1 \rangle)$ factors as a composition

$$F(\langle n \rangle) \to F(\langle 1 \rangle) \to F(1).$$

The first map is inert by virtue of our assumption that $F|E_0^S \in \text{Alg}_{/S}(0)$, and the second map is an equivalence since $F$ satisfies condition (a). It follows that $F$ satisfies the hypothesis of (i') and is therefore a $p$-right Kan extension of $F|\Delta^1$. This completes the proof of (i).

The proof of (ii) is similar: using Lemma T.4.3.2.7, we can reduce to showing that for each $n \geq 0$ the composite map

$$N(\mathcal{J}_1) \to \{1\} \subseteq \Delta^1 \xrightarrow{F_1} \mathcal{O}^S$$

can be extended to a $p$-limit diagram (lying over the canonical map $N(\mathcal{J}_1)^o \to N(\beta) \to E_0^S$). The existence of such a diagram follows immediately from Proposition 2.1.2.12.

### 2.1.4 $\infty$-Preoperads

The collection of all $\infty$-operads can be organized into a simplicial category $\text{Op}_\infty^\Delta$, which we define as follows:

- The objects of $\text{Op}_\infty^\Delta$ are (small) $\infty$-operads $\mathcal{O}^S \to N(\text{Fin}_*)$.
- For every pair of $\infty$-operads $\mathcal{O}^S, \mathcal{O}'^S \in \text{Op}_\infty^\Delta$, we define $\text{Map}_{\text{Op}_\infty^\Delta}(\mathcal{O}^S, \mathcal{O}'^S)$ to be the Kan complex $\text{Alg}_S(\mathcal{O}'^S)^{\infty}_{\mathcal{O}}$ of $\infty$-operad maps from $\mathcal{O}^S$ to $\mathcal{O}'^S$.

**Definition 2.1.4.1.** We define $\text{Op}_\infty$ to be the nerve of the simplicial category $\text{Op}_\infty^\Delta$. We will refer to $\text{Op}_\infty$ as the $\infty$-category of $\infty$-operads.

Because the mapping spaces in $\text{Op}_\infty^\Delta$ are Kan complexes, the simplicial set $\text{Op}_\infty$ is an $\infty$-category (Proposition T.1.1.5.10). Our goal in this section is to study the $\infty$-category $\text{Op}_\infty$. We will show that $\text{Op}_\infty$ is a presentable $\infty$-category: in particular, it admits small limits and colimits. To prove this, we will exhibit $\text{Op}_\infty$ as the underlying $\infty$-category of a combinatorial simplicial model category $\mathcal{P} \text{Op}_\infty$, which we call the category of $\infty$-preoperads.

Recall that a marked simplicial set is a pair $(X, M)$, where $X$ is a simplicial set and $M$ is a collection of edges of $X$, which contains all degenerate edges (see §T.3.1). If $X$ is a simplicial set, we let $X^\dagger$ denote the marked simplicial set $(X, M)$ where $M$ consists of all edges of $X$, and $X^\flat$ the marked simplicial set $(X, M)$ where $M$ consists of all the degenerate edges of $X$. The category of marked simplicial sets will be denoted by $\text{Set}_\Delta^+$.

**Definition 2.1.4.2.** An $\infty$-preoperad is a marked simplicial set $(X, M)$ equipped with a map of simplicial sets $f : X \to N(\text{Fin}_*)$ with the following property: for each edge $e$ of $X$ which belongs to $M$, the image $f(e)$ is an inert morphism in $\text{Fin}_*$.

A morphism from an $\infty$-preoperad $(X, M)$ to an $\infty$-preoperad $(Y, N)$ is a map of marked simplicial sets $(X, M) \to (Y, N)$ such that the diagram

$$
\begin{array}{ccc}
X & \to & Y \\
\downarrow & & \downarrow \\
N(\text{Fin}_*) & \to & N(\text{Fin}_*)
\end{array}
$$

commutes. The collection of $\infty$-preoperads (and $\infty$-preoperad morphisms) forms a category, which we will denote by $\mathcal{P} \text{Op}_\infty$. 

**Remark 2.1.4.3.** The category \( \mathcal{P} \text{Op}_\infty \) can be identified with the overcategory \( \text{Set}^+_\text{N(Flin_\ast)} \), where \( M \) is the collection of all inert morphisms in \( \text{N(Flin_\ast)} \).

**Remark 2.1.4.4.** The category \( \mathcal{P} \text{Op}_\infty \) of \( \infty \)-preoperads is naturally tensored over simplicial sets: if \( \mathcal{X} \) is an \( \infty \)-preoperad and \( K \) is a simplicial set, we let \( \mathcal{X} \otimes K = \mathcal{X} \times K^2 \). This construction endows \( \mathcal{P} \text{Op}_\infty \) with the structure of a simplicial category.

**Notation 2.1.4.5.** Let \( \mathcal{O}^\infty \) be an \( \infty \)-operad. We let \( \mathcal{O}^\infty,^\ast \) denote the \( \infty \)-preoperad \( (\mathcal{O}^\infty, M) \), where \( M \) is the collection of all inert morphisms in \( \mathcal{O}^\infty \).

**Proposition 2.1.4.6.** There exists a left proper combinatorial simplicial model structure on \( \mathcal{P} \text{Op}_\infty \) which may be characterized as follows:

(C) A morphism \( f : \mathcal{X} \to \mathcal{Y} \) in \( \mathcal{P} \text{Op}_\infty \) is a cofibration if and only if it induces a monomorphism between the underlying simplicial sets of \( \mathcal{X} \) and \( \mathcal{Y} \).

(W) A morphism \( f : \mathcal{X} \to \mathcal{Y} \) in \( \mathcal{P} \text{Op}_\infty \) is a weak equivalence if and only if, for every \( \infty \)-operad \( \mathcal{O}^\infty \), the induced map
\[
\text{Map}_{\mathcal{P} \text{Op}_\infty}(\mathcal{Y}, \mathcal{O}^\infty,^\ast) \to \text{Map}_{\mathcal{P} \text{Op}_\infty}(\mathcal{X}, \mathcal{O}^\infty,^\ast)
\]

is a weak homotopy equivalence of simplicial sets.

This model structure is compatible with the simplicial structure of Remark 2.1.4.4. Moreover, if \( \mathcal{O}^\infty \) is an \( \infty \)-operad, then a map \( \alpha : \mathcal{X} \to \mathcal{O}^\infty,^\ast \) in \( \mathcal{P} \text{Op}_\infty \) is a fibration if and only if there exists a fibration of \( \infty \)-operads \( \mathcal{O}^\infty \to \mathcal{O}^\infty \) (see Definition 2.1.2.10) such that \( \alpha \) is induced by an equivalence \( \mathcal{X} \simeq \mathcal{O}^\infty,^\ast \). In particular (taking \( \mathcal{O}^\infty = N(\text{Fin_\ast}) \)), we deduce that an object \( \mathcal{X} \in \mathcal{P} \text{Op}_\infty \) is fibrant if and only if it has the form \( \mathcal{C}^\infty,^\ast \), for some \( \infty \)-operad \( \mathcal{C}^\infty \).

Proposition 2.1.4.6 can be deduced from much more general results which we will prove in §B.4. In what follows, we will freely use the terminology developed in the appendix.

**Proof of Proposition 2.1.4.6.** Let \( \mathfrak{P} = (M, T, \{p_\alpha : A_{\alpha}^2 \to N(\text{Fin_\ast})\}_{\alpha \in A}) \) be the categorical pattern on \( N(\text{Fin_\ast}) \) where \( M \) consists of all inert morphisms, \( T \) the collection of all 2-simplices, and \( A \) ranges over all diagrams
\[
\langle p \rangle \leftarrow \langle n \rangle \to \langle q \rangle
\]
where the maps are inert and determine a bijection \( \langle p \rangle^\ast \coprod \langle q \rangle^\ast \to \langle n \rangle^\ast \). The main result now follows from Theorem B.0.20, and the characterization of fibrations between fibrant objects follows from Proposition B.2.7. \( \square \)

**Remark 2.1.4.7.** We will refer to the model structure of Proposition 2.1.4.6 as the \( \infty \)-operadic model structure on \( \mathcal{P} \text{Op}_\infty \).

**Example 2.1.4.8.** The inclusion \( \{(1)\}^b \subseteq \text{Triv}^\infty,^\infty \) is a weak equivalence of \( \infty \)-preoperads. This is an immediate consequence of Example 2.1.3.5. In other words, we can view \( \text{Triv}^\infty,^\infty \) as a fibrant replacement for the object \( \{(1)\}^b \in \mathcal{P} \text{Op}_\infty \).

**Example 2.1.4.9.** Using Proposition 2.1.3.9, we deduce that the morphism \( (0) \to (1) \) in \( \text{Fin_\ast} \) induces a weak equivalence of \( \infty \)-preoperads \( (\Delta^1)^b \subseteq \mathcal{E}^\infty_0,^\infty \), so that \( \mathcal{E}^\infty_0,^\infty \) can be viewed as a fibrant replacement for the \( \infty \)-preoperad \( (\Delta^1)^b \).

**Remark 2.1.4.10.** The \( \infty \)-operadic model structure on \( \mathcal{P} \text{Op}_\infty \) induces a model structure on the category \( \mathcal{P} \text{Op}_\infty/\{(1)\}^b \simeq \text{Set}_\Delta^+ \). Unwinding the definitions, we see that a morphism of marked simplicial sets \( \alpha : (X, M) \to (X', M') \) is a cofibration (with respect to this model structure) if and only if the underlying map of simplicial sets \( X \to X' \) is a monomorphism, and is a weak equivalence if and only if it induces a homotopy equivalence \( \text{Map}_{\text{Set}_\Delta^+}(\mathcal{Y}, M') \to \text{Map}_{\text{Set}_\Delta^+}(\mathcal{Y}) \) whenever \( \mathcal{Y} \) is a marked simplicial set of the form...
2.1. FOUNDATIONS

\(\mathcal{O}^\otimes \times_{\mathcal{N}(\mathrm{Fin}_*)} \{\langle 1 \rangle\}^b\), for some \(\infty\)-operad \(\mathcal{O}^\otimes\). This is true if and only if \(\mathcal{Y}\) has the form \((\mathcal{C}, M)\), where \(\mathcal{C}\) is an \(\infty\)-category and \(M\) is the collection of all equivalences in \(\mathcal{C}\) (the "only if" assertion is obvious, and the converse implication follows by taking \(\mathcal{O}^\otimes\) to be the \(\infty\)-operad \(\mathcal{C}^\otimes\) of Proposition 2.4.1.5). It follows that the induced model structure on \(\mathsf{Set}_\Delta\) coincides with the marked model structure of \(\mathfrak{T}_3\).1, so that we can identify the underlying \(\infty\)-category \(\mathcal{N}(\mathsf{Set}_\Delta^\otimes)\) with \(\mathcal{C}^\otimes\).

Composing with the inclusion \(\{\langle 1 \rangle\}^b \to \mathcal{N}(\mathsf{Fin}_*)^b\), we obtain a left Quillen functor

\[ F : \mathsf{Set}_\Delta^\otimes \simeq (\mathcal{P}^\otimes_\infty)/(\{\langle 1 \rangle\}^b) \to \mathcal{P}_\infty^\otimes. \]

This functor has a right adjoint \(G : \mathcal{P}_\infty^\otimes \to \mathsf{Set}_\Delta^\otimes\), which assigns to an \(\infty\)-preoperad \(\mathcal{X}\) the fiber product \(\mathcal{X} \times_{\mathcal{N}(\mathsf{Fin}_*)} \{\langle 1 \rangle\}^b\). Passing to the underlying \(\infty\)-categories, we see that \(G\) induces the functor \(g : \mathcal{P}_\infty^\otimes \to \mathcal{C}^\otimes\) which assigns to each \(\infty\)-operad \(\mathcal{O}^\otimes\) its underlying \(\infty\)-category \(\mathcal{O}\). The left Quillen functor \(F\) induces a left adjoint \(f : \mathcal{C}^\otimes \to \mathcal{P}_\infty^\otimes\).

**Proposition 2.1.4.11.** The functor \(f : \mathcal{C}^\otimes \to \mathcal{P}_\infty^\otimes\) is fully faithful. An \(\infty\)-operad \(q : \mathcal{O}^\otimes \to \mathcal{N}(\mathsf{Fin}_*)\) belongs to the essential image of \(f\) if and only if the functor \(q\) factors through the subcategory \(\mathfrak{T}_2^\otimes \subset \mathcal{N}(\mathsf{Fin}_*)\).

**Proof.** Let \(\mathcal{O}_\infty^\prime \subseteq \mathcal{P}_\infty^\otimes\) be the full subcategory spanned by those \(\infty\)-operads \(q : \mathcal{O}^\otimes \to \mathcal{N}(\mathsf{Fin}_*)\) such that \(q\) factors through \(\mathfrak{T}_2^\otimes\). It is easy to see that the inclusion \(f' : \mathcal{O}_\infty^\prime \subseteq \mathcal{P}_\infty^\otimes\) admits a right adjoint \(g'\), given by \(\mathcal{O}^\otimes \to \mathcal{O}^\otimes \times_{\mathcal{N}(\mathsf{Fin}_*)} \mathfrak{T}_2^\otimes\). The evaluation functor \(q : \mathcal{P}_\infty^\otimes \to \mathcal{C}^\otimes\) factors as a composition

\[ \mathcal{O}^\otimes \xrightarrow{q} \mathcal{O}_\infty^\prime \to \mathcal{O}_\infty^\prime \to \mathcal{C}^\otimes, \]

where \(g'' = g|_{\mathcal{O}_\infty^\prime}\). It follows that \(f \simeq f' \circ f''\), where \(f''\) is a left adjoint to \(g''\). Note that if \(q : \mathcal{O}^\otimes \to \mathcal{N}(\mathsf{Fin}_*)\) belongs to \(\mathcal{O}_\infty^\prime\), then \(q\) is a coCartesian fibration; moreover, every morphism in \(\mathcal{O}_\infty^\prime\) corresponds to a commutative diagram

\[ \mathcal{O}^\otimes \xrightarrow{T} \mathcal{O}^\otimes \]

where \(T\) carries \(q\)-coCartesian morphisms to \(q'\)-coCartesian morphisms. Using Theorem T.3.2.0.1, we deduce that \(\mathcal{O}_\infty^\prime\) is equivalent to a full subcategory \(\mathsf{Fun}'(\mathfrak{T}_2^\otimes, \mathcal{C}^\otimes) \to \mathsf{Fun}(\mathfrak{T}_2^\otimes, \mathcal{C}^\otimes)\): namely, the full subcategory consisting of those functors \(\chi : \mathfrak{T}_2^\otimes \to \mathcal{C}^\otimes\) which are right Kan extensions of \(\chi|_{\{\langle 1 \rangle\}}\).

Using Proposition T.4.3.2.15, we deduce that evaluation at \(\{\langle 1 \rangle\}\) induces an equivalence of \(\infty\)-categories \(\mathsf{Fun}'(\mathfrak{T}_2^\otimes, \mathcal{C}^\otimes) \to \mathcal{C}^\otimes\). It follows that \(g''\) is an equivalence of \(\infty\)-categories, so that \(f'' \simeq (g'')^{-1}\) is an equivalence and \(f \simeq f' \circ f''\) is fully faithful. \(\blacksquare\)

**Remark 2.1.4.12.** Proposition 2.1.4.11 is equivalent to the assertion that the weak equivalence \(\{\langle 1 \rangle\}^b \subseteq \mathfrak{T}_2^\otimes\) of Example 2.1.4.8 induces a left Quillen equivalence of model categories

\[ (\mathcal{P}_\infty^\otimes)/(\{\langle 1 \rangle\}^b) \to (\mathcal{P}_\infty^\otimes)/\mathfrak{T}_2^\otimes_{1}. \]

This statement is not completely formal: the model category \(\mathcal{P}_\infty^\otimes\) is not right proper, and the object \(\{\langle 1 \rangle\}^b \in \mathcal{P}_\infty^\otimes\) is not fibrant.

**Variant 2.1.4.13.** We define a subcategory \(\mathcal{C}^\otimes \subset \mathcal{P}_\infty^\otimes\) as follows:

- An object \(\mathcal{C}^\otimes\) of \(\mathcal{P}_\infty^\otimes\) belongs to \(\mathcal{C}^\otimes\) if and only if it is a symmetric monoidal \(\infty\)-category.

- A morphism \(\mathcal{C}^\otimes \to \mathcal{O}^\otimes\) in \(\mathcal{P}_\infty^\otimes\) belongs to \(\mathcal{C}^\otimes\) if and only if it is a symmetric monoidal functor.

We will refer to \(\mathcal{C}^\otimes\) as the **\(\infty\)**-category of symmetric monoidal \(\infty\)-categories. Using Theorem B.0.20, we deduce that \(\mathcal{C}^\otimes\) can be realized as the underlying \(\infty\)-category of the combinatorial simplicial model category \((\mathsf{Set}_\Delta^+)^{\mathfrak{P}}\), where \(\mathfrak{P}\) denotes the categorical pattern \((\mathcal{M}', \mathcal{T}; \{p_\alpha : A^2_0 \to \mathcal{N}(\mathsf{Fin}_*)\}_{\alpha \in A})\) on the simplicial set \(\mathcal{N}(\mathsf{Fin}_*)\), where \(\mathcal{T}\) and \(\{p_\alpha : A^2_0 \to \mathcal{N}(\mathsf{Fin}_*)\}_{\alpha \in A}\) are defined as in the proof of Proposition 2.1.4.6, while \(\mathcal{M}'\) consists of all edges of \(\mathfrak{P}\)
2.2 Constructions of $\infty$-Operads

In this section, we will describe how various categorical constructions can be generalized to the setting of symmetric monoidal $\infty$-categories (or the more general setting of $\infty$-operads). Suppose that $\mathcal{C}$ is an $\infty$-category equipped with a symmetric monoidal structure, and that $\mathcal{D}$ is another $\infty$-category which is obtained from $\mathcal{C}$ via some natural procedure; under what conditions does $\mathcal{D}$ inherit a symmetric monoidal structure?

We will begin in §2.2.1 by considering the construction of full subcategories. If $\mathcal{C}$ is a symmetric monoidal $\infty$-category and $S$ is a collection of objects of $\mathcal{C}$, then we can consider the full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ spanned by the objects of $S$ (see §T.1.2.11). If the collection of objects $S$ is stable under tensor products, then $\mathcal{C}_0$ inherits a symmetric monoidal structure (Proposition 2.2.1.1). However, there are other situations where the same phenomenon occurs: for example, if $\mathcal{C}_0$ is a localization of $\mathcal{C}$, then a symmetric monoidal structure on $\mathcal{C}$ sometimes yields a symmetric monoidal structure on $\mathcal{C}_0$ by passage to the quotient (Proposition 2.2.1.9).

If $\mathcal{C}$ is a symmetric monoidal $\infty$-category and $X \in \mathcal{C}$ is an object, then the $\infty$-categories $\mathcal{C}_{X/}$ and $\mathcal{C}/_X$ generally do not inherit symmetric monoidal structures. However, if $X$ is a commutative algebra object of $\mathcal{C}$, then the situation is somewhat better. In §2.2.2, we will show that the overcategory $\mathcal{C}_{/X}$ inherits a symmetric monoidal structure when $X$ is a commutative algebra object of $\mathcal{C}$. In this situation, the undercategory $\mathcal{C}_{X/}$ generally does not inherit a symmetric monoidal structure, but it can nevertheless be regarded as an $\infty$-operad (see Theorem 2.2.2.4). Some other categorical constructions are better behaved at the level of $\infty$-operads. For example, suppose we are given a pair of $\infty$-operad $\mathcal{O}^\otimes$ and $\mathcal{O}'^\otimes$, having underlying $\infty$-categories $\mathcal{O}$ and $\mathcal{O}'$. In §2.2.3, we will show that the disjoint union $\mathcal{O} \sqcup \mathcal{O}'$ is equivalent to the underlying $\infty$-category of an $\infty$-operad which we will denote by $\mathcal{O}^\otimes \boxtimes \mathcal{O}'^\otimes$. Moreover, the $\infty$-operad $\mathcal{O}^\otimes \boxtimes \mathcal{O}'^\otimes$ plays the role of the coproduct in the setting of $\infty$-operads (Theorem 2.2.3.6).

In §2.2.4, we will study the interplay between the theories of symmetric monoidal $\infty$-categories and $\infty$-operads. By definition, every symmetric monoidal $\infty$-category $\mathcal{O}^\otimes \to \mathcal{N}(\mathcal{F}_{\mathcal{M}})$ can be regarded as an $\infty$-operad. The resulting forgetful functor from symmetric monoidal $\infty$-categories to $\infty$-operads has a left adjoint: that is, to every $\infty$-operad $\mathcal{O}^\otimes$, one can associate a symmetric monoidal $\infty$-category $\mathcal{O}^\otimes_{\mathcal{M}}$, so that $\mathcal{F}_\mathcal{O}(\mathcal{O}, \mathcal{C}) \simeq \mathcal{O}^\otimes_{\mathcal{M}}(\mathcal{C})$ for any symmetric monoidal $\infty$-category $\mathcal{C}^\otimes$ (see Proposition 2.2.4.9).

Some categorical constructions admit more than one generalization to the $\infty$-operadic setting. For example, the formation of Cartesian products of $\infty$-categories admits two natural generalizations: in addition to the Cartesian product, the $\infty$-category $\mathcal{O}_\mathcal{M}^\otimes$ admits a symmetric monoidal structure $\otimes$ which can be described informally as follows: for every pair of $\infty$-operads $\mathcal{O}^\otimes$ and $\mathcal{O}'^\otimes$, the tensor product $\mathcal{O}^\otimes \otimes \mathcal{O}'^\otimes = \mathcal{O}^\otimes_{\mathcal{M}} \otimes \mathcal{O}'^\otimes_{\mathcal{M}}$ is characterized by the requirement that for every symmetric monoidal $\infty$-category $\mathcal{C}^\otimes$, we have an equivalence of $\infty$-categories

$$\mathcal{O}^\otimes_{\mathcal{M}}(\mathcal{C}) \simeq \mathcal{O}^\otimes_{\mathcal{M}}(\mathcal{C}) \simeq \mathcal{O}^\otimes_{\mathcal{M}}(\mathcal{C});$$

here we view $\mathcal{O}^\otimes_{\mathcal{M}}(\mathcal{C})$ as a symmetric monoidal $\infty$-category via pointwise tensor product. We will give a careful definition of this tensor product (and prove that it endows $\mathcal{O}_\mathcal{M}^\otimes$ with a symmetric monoidal structure) in §2.2.5, essentially by formalizing the universal property stated above.

**Remark 2.2.0.1.** Our tensor product of $\infty$-operads $\mathcal{O}^\otimes \otimes \mathcal{O}'^\otimes$ is a version of the Boardman-Vogt tensor product. For more details, we refer the reader to [19], [20], and [41].

2.2.1 Subcategories of $\mathcal{O}$-Monoidal $\infty$-Categories

Let $\mathcal{C}^\otimes$ be an $\infty$-operad, and let $\mathcal{D} \subseteq \mathcal{C}$ be a full subcategory of the underlying $\infty$-category of $\mathcal{C}^\otimes$ which is stable under equivalence. In this case, we let $\mathcal{D}^\otimes$ denote the full subcategory of $\mathcal{C}^\otimes$ spanned by those objects $D \in \mathcal{C}^\otimes$ having the form $D_1 \oplus \cdots \oplus D_n$, where each object $D_i$ belongs to $\mathcal{D}$. It follows immediately from the definitions that $\mathcal{D}^\otimes$ is again an $\infty$-operad, and that the inclusion $\mathcal{D}^\otimes \subseteq \mathcal{C}^\otimes$ is a map of $\infty$-operads. In this section, we will consider some refinements of the preceding statement: namely, we will suppose that there exists a coCartesian fibration of $\infty$-operads $p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$, and obtain criteria which guarantee that $p|\mathcal{D}^\otimes$ is
2.2. CONSTRUCTIONS OF ∞-OPERADS

again a coCartesian fibration of ∞-operads. The most obvious case to consider is that in which \( \mathcal{D} \) is stable under the relevant tensor product operations on \( \mathcal{C} \).

**Proposition 2.2.1.1.** Let \( p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a coCartesian fibration of ∞-operads, let \( \mathcal{D} \subseteq \mathcal{C} \) be a full subcategory which is stable under equivalence, and let \( \mathcal{D}^\otimes \subseteq \mathcal{C}^\otimes \) be defined as above. Suppose that, for every operation \( f \in \text{Mul}_0(\{X_i\}, Y) \), the functor \( \otimes_f : \prod_{1 \leq i \leq n} \mathcal{C}_{X_i} \to \mathcal{C}_Y \) defined in Remark 2.1.2.16 carries \( \prod_{1 \leq i \leq n} \mathcal{D}_{X_i} \), into \( \mathcal{D}_Y \). Then:

1. The restricted map \( \mathcal{D}^\otimes \to \mathcal{O}^\otimes \) is a coCartesian fibration of ∞-operads.
2. The inclusion \( \mathcal{D}^\otimes \subseteq \mathcal{C}^\otimes \) is a \( \mathcal{O} \)-monoidal functor.

3. Suppose that, for every object \( X \in \mathcal{O} \), the inclusion \( \mathcal{D}_X \subseteq \mathcal{C}_X \) admits a right adjoint \( L_X \) (so that \( \mathcal{D}_X \) is a colocalization of \( \mathcal{C}_X \)). Then there exists a commutative diagram

\[
\begin{array}{ccc}
\mathcal{C}^\otimes & \xrightarrow{L^\otimes} & \mathcal{D}^\otimes \\
p & & ↓ \\
\mathcal{O}^\otimes & \xrightarrow{id} & \mathcal{D}^\otimes
\end{array}
\]

and a natural transformation of functors \( \alpha : L^\otimes \to \text{id}_{\mathcal{C}^\otimes} \) which exhibits \( L^\otimes \) as a colocalization functor (see Proposition T.5.2.7.4) and such that, for every object \( C \in \mathcal{C}^\otimes \), the image \( p(\alpha(C)) \) is a degenerate edge of \( \mathcal{O}^\otimes \).

4. Under the hypothesis of (3), the functor \( L^\otimes \) is a map of ∞-operads.

**Remark 2.2.1.2.** Assume that \( \mathcal{O}^\otimes \) is the commutative ∞-operad, and let \( \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a symmetric monoidal ∞-category. A full subcategory \( \mathcal{D} \subseteq \mathcal{C} \) (stable under equivalence) satisfies the hypotheses of Proposition 2.2.1.1 if and only if \( \mathcal{D} \) contains the unit object of \( \mathcal{C} \) and is closed under the tensor product functor \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \).

**Example 2.2.1.3.** Let \( \mathcal{O}^\otimes \) be an ∞-operad, and suppose we are given a coCartesian fibration of ∞-operads \( p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \). Assume that for each \( X \in \mathcal{O} \), the ∞-category \( \mathcal{C}_X \) is stable, and that for every operation \( \phi \in \text{Mul}_0(\{X_i\}, Y) \) the associated functor \( \otimes_{\phi} : \prod_{i \in I} \mathcal{C}_{X_i} \to \mathcal{C}_Y \) is exact in each variable. We will say that a family of t-structures \((\mathcal{C}_X_{\geq 0}, (\mathcal{C}_X)_{<0})\) is compatible with \( p \) if, for each \( \phi \in \text{Mul}_0(\{X_i\}, Y) \), the functor \( \otimes_{\phi} \) carries \( \prod_{i \in I} \mathcal{C}_{X_i} \) into \( (\mathcal{C}_Y_{\geq 0}, (\mathcal{C}_Y)_{<0}) \). Let \( \mathcal{C}^\otimes_{\geq 0} \subseteq \mathcal{C}^\otimes \) be the full subcategory spanned by the objects \( C \in \mathcal{C}^\otimes \) such that, for every inert morphism \( C \to C' \), where \( C' \in \mathcal{C}_X \) for some \( X \in \mathcal{O} \), the object \( C' \) belongs to \( (\mathcal{C}_X)_{\geq 0} \). Proposition 2.2.1.1 implies that the induced map \( \mathcal{C}^\otimes_{\geq 0} \to \mathcal{O}^\otimes \) is again a coCartesian fibration of ∞-operads.

**Remark 2.2.1.4.** Let \( \mathcal{C}^\otimes \to \text{Ass}^\otimes \) be a coCartesian fibration of ∞-operads satisfying the hypotheses of Example 2.2.1.3. Then, for every pair of integers \( m, n \in \mathbb{Z} \), the tensor product functor \( \otimes \) carries \( \mathcal{C}_{\geq m} \times \mathcal{C}_{\geq n} \) into \( \mathcal{C}_{\geq m+n} \). This follows immediately from the exactness of the tensor product in each variable, and the assumption that the desired result holds in the case \( m = n = 0 \).

**Proof of Proposition 2.2.1.1.** Assertions (1) and (2) follow immediately from the definitions. Now suppose that the hypotheses of (3) are satisfied. Let us say that a morphism \( f : D \to C \) in \( \mathcal{C}^\otimes \) is colocalizing if \( D \in \mathcal{D}^\otimes \), and the projection map

\[
\psi : \mathcal{D}^\otimes \times_{\mathcal{C}^\otimes} \mathcal{C}^\otimes_{/f} \to \mathcal{D}^\otimes \times_{\mathcal{C}^\otimes} \mathcal{C}^\otimes_{/C}
\]

is a trivial Kan fibration. Since \( \psi \) is automatically a right fibration (Proposition T.2.1.2.1), the map \( f \) is colocalizing if and only if the fibers of \( \psi \) are contractible (Lemma T.2.1.3.4). For this, it suffices to show that for each \( D' \in \mathcal{D}^\otimes \), the induced map of fibers

\[
\psi_{D'} : \{D'\} \times_{\mathcal{C}^\otimes} \mathcal{C}^\otimes_{/f} \to \{D'\} \times_{\mathcal{C}^\otimes} \mathcal{C}^\otimes_{/C}
\]
has contractible fibers. Since \( \psi_{D'} \) is a right fibration between Kan complexes, it is a Kan fibration (Lemma T.2.1.3.3). Consequently, \( \psi_{D'} \) has contractible fibers if and only if it is a homotopy equivalence. In other words, \( f \) is colocalizing if and only if composition with \( f \) induces a homotopy equivalence \( \text{Map}_{\mathcal{C}}(D', D) \to \text{Map}_{\mathcal{C}}(D, C) \) for all \( D' \in \mathcal{D}^\otimes \).

Suppose now that \( f : D \to C \) is a morphism belonging to a particular fiber \( \mathcal{C}^\otimes_X \) of \( p \). Then, for every object \( D' \in \mathcal{C}^\otimes_Y \), we have canonical maps

\[
\text{Map}_{\mathcal{C}}(D', D) \to \text{Map}_{\mathcal{C}}(Y, X) \leftarrow \text{Map}_{\mathcal{C}}(D', C)
\]

whose homotopy fibers over a morphisms \( g : Y \to X \) in \( \mathcal{O}^\otimes \) can be identified with \( \text{Map}_{\mathcal{C}}(g D', D) \) and \( \text{Map}_{\mathcal{C}}(g D', C) \) (Proposition T.2.4.4.2). Our hypothesis that \( \mathcal{D} \) is stable under the tensor operations on \( \mathcal{C} \) implies that \( g D' \in \mathcal{D}^\otimes \). It follows that \( f \) is colocalizing in \( \mathcal{C}^\otimes \) if and only if it is colocalizing in \( \mathcal{C}^\otimes_X \).

To prove (3), we need to construct a commutative diagram

\[
\begin{array}{ccc}
\mathcal{C}^\otimes \times \Delta^1 & \xrightarrow{\alpha} & \mathcal{C}^\otimes \\
\downarrow{\partial \Delta^1} & & \downarrow{p} \\
\partial \mathcal{C}^\otimes \times \Delta^1 & \xrightarrow{\alpha_0} & \partial \mathcal{C}^\otimes
\end{array}
\]

with \( \alpha|_{\mathcal{C}^\otimes \times \{1\}} \) equal to the identity, and having the property that, for every object \( C \in \mathcal{C}^\otimes \), the restriction \( \alpha|_{\{C\} \times \Delta^1} \) is colocalizing. For this, we construct \( \alpha \) one simplex at a time. To define \( \alpha \) on a vertex \( C \in \mathcal{C}^\otimes_X \) where \( X \in \mathcal{O}^\otimes_{(n)} \) corresponds to a sequence of objects \( \{X_i\}_{1 \leq i \leq n} \) in \( \mathcal{O} \), we use the equivalence \( \mathcal{C}^\otimes_X \simeq \prod_{1 \leq i \leq n} \mathcal{C}_X \) and the assumption that each \( \mathcal{D}_X \subseteq \mathcal{C}_X \) is a colocalization. For simplices of higher dimension, we need to solve extensions problems of the form

\[
(\partial \Delta^n \times \Delta^1) \coprod_{\theta \Delta^n \times \{1\}} (\Delta^n \times \{1\}) \xrightarrow{\alpha_0} \mathcal{C}^\otimes
\]

where \( n > 0 \) and \( \alpha_0 \) carries each of the edges \( \{i\} \times \Delta^1 \) to a colocalizing morphism in \( \mathcal{C}^\otimes \). We now observe that \( \Delta^n \times \Delta^1 \) admits a filtration

\[
X_0 \subseteq X_1 \subseteq \ldots \subseteq X_n \subseteq X_{n+1} = \Delta^n \times \Delta^1,
\]

where \( X_0 = (\partial \Delta^n \times \Delta^1) \coprod_{\theta \Delta^n \times \{1\}} (\Delta^n \times \{1\}) \) and there exist pushout diagrams

\[
\begin{array}{ccc}
\Lambda^{n+1}_{i+1} & \to & \Delta^{n+1} \\
\downarrow & & \downarrow \\
X_i & \to & X_{i+1}
\end{array}
\]

We now argue, by induction on \( i \), that the map \( \alpha_0 \) admits an extension to \( X_i \) (compatible with the projection \( p \)). For \( i \leq n \), this follows from the fact that \( p \) is an inner fibration. For \( i = n+1 \), it follows from the definition of a colocalizing morphism. This completes the proof of (3). Assertion (4) follows from the construction. \( \square \)

**Remark 2.2.1.5.** Let \( \mathcal{D}^\otimes \subseteq \mathcal{C}^\otimes \) be as in the statement of Proposition 2.2.1.1, and suppose that each inclusion \( \mathcal{D}_X \subseteq \mathcal{C}_X \) admits a right adjoint \( L_X \). The inclusion \( i : \mathcal{D}^\otimes \subseteq \mathcal{C}^\otimes \) is a \( \mathcal{O} \)-monoidal functor, and therefore induces a fully faithful embedding \( \text{Alg}_{/\mathcal{O}}(\mathcal{D}) \subseteq \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \). Let \( L^\otimes \) be the functor constructed in Proposition 2.2.1.1. Since \( L^\otimes \) is a map of \( \infty \)-operads, it also induces a functor \( f : \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \to \text{Alg}_{/\mathcal{O}}(\mathcal{D}) \). It is not difficult to see that \( f \) is right adjoint to the inclusion \( \text{Alg}_{/\mathcal{O}}(\mathcal{D}) \subseteq \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \). Moreover, if \( \theta : \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \to \mathcal{C}_X \) denotes the evaluation functor associated to an object \( X \in \mathcal{O} \), then for each \( A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \) the map \( \theta(f(A)) \to \theta(A) \) induced by the colocalization map \( f(A) \to A \) determines an equivalence \( \theta(f(A)) \simeq L_X \theta(A) \).
Proposition 2.2.1.1 has an obvious converse: if \( i : \mathcal{D}^\otimes \to \mathcal{C}^\otimes \) is a fully faithful \( \mathcal{O} \)-monoidal functor between \( \mathcal{O} \)-monoidal \( \infty \)-categories, then the essential image of \( \mathcal{D} \) in \( \mathcal{C} \) is stable under the tensor operations of Remark 2.1.2.16. However, it is possible for this converse to fail if we assume only that \( i \) is lax monoidal.

We now discuss a general class of examples where \( \mathcal{D} \) is not stable under tensor products, yet \( \mathcal{D} \) nonetheless inherits a \( \mathcal{O} \)-monoidal structure from that of \( \mathcal{C} \).

**Definition 2.2.1.6.** Let \( \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a coCartesian fibration of \( \infty \)-operads and suppose we are given a family of localization functors \( L_X : \mathcal{C}_X \to \mathcal{C}_X \) for \( X \in \mathcal{O} \). We will say that the family \( \{ L_X \}_X \in \mathcal{O} \) is compatible with the \( \mathcal{O} \)-monoidal structure on \( \mathcal{C} \) if the following condition is satisfied:

\[
(*) \text{ Let } f \in \text{Mul}_\mathcal{O} \{ \{ X_i \} \}_{1 \leq i \leq n}, Y \text{ be an operation in } \mathcal{O}, \text{ and suppose we are given morphisms } g_i \in \mathcal{C}_{X_i} \text{ for } 1 \leq i \leq n. \text{ If each } g_i \text{ is a } L_{X_i} \text{-equivalence, then the morphism } \otimes_f \{ g_i \} \}_{1 \leq i \leq n} \text{ in } \mathcal{C}_Y \text{ is an } L_Y \text{-equivalence.}
\]

**Example 2.2.1.7.** In the situation where \( \mathcal{O}^\otimes \) is the commutative \( \infty \)-operad, the condition of Definition 2.2.1.6 can be simplified: a localization functor \( L : \mathcal{C} \to \mathcal{C} \) is compatible with a symmetric monoidal structure on \( \mathcal{C} \) if and only if, for every \( L \)-equivalence \( X \to Y \) in \( \mathcal{C} \) and every object \( Z \in \mathcal{C} \), the induced map \( X \otimes Z \to Y \otimes Z \) is again an \( L \)-equivalence.

**Proposition 2.2.1.8.** Let \( p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a coCartesian fibration of \( \infty \)-operads. Assume that for each \( X \in \mathcal{O} \), the \( \infty \)-category \( \mathcal{C}_X \) is stable, and that for every operation \( \phi \in \text{Mul}_\mathcal{O} \{ \{ X_i \}_i \}, Y \) the associated functor \( \otimes_\phi : \prod_{i \in I} \mathcal{C}_{X_i} \to \mathcal{C}_Y \) is exact in each variable. Suppose we are given a collection of t-structures on the \( \infty \)-categories \( \mathcal{C}_X \) which are compatible with \( p \) (in the sense of Example 2.2.1.3), so that we have an induced coCartesian fibration \( \mathcal{C}^\otimes_\mathcal{O} \to \mathcal{O}^\otimes \). Then the collection of localization functors \( \tau_{\leq n} : (\mathcal{C}_X)_{\geq 0} \to (\mathcal{C}_X)_{\geq 0} \) is compatible with the \( \mathcal{O} \)-monoidal structure on \( \mathcal{C}_{\geq 0} \) (in the sense of Definition 2.2.1.6).

**Proof.** Suppose we are given an operation \( \phi \in \text{Mul}_\mathcal{O} \{ \{ X_i \}_i \}, Y \), so that \( \phi \) induces a tensor product functor \( \otimes_\phi : \prod_{i \in I} \mathcal{C}_{X_i} \to \mathcal{C}_Y \). We must show that if we are given a collection of morphisms \( \alpha_i : C_i \to C_i' \) in \( (\mathcal{C}_X)_{\geq 0} \) which induce equivalences \( \tau_{\leq k} C_i \to \tau_{\leq k} C_i' \), then the induced map

\[
\tau_{\leq k} \otimes_\phi (\{ C_i \}) \to \tau_{\leq k} \otimes_\phi (\{ C_i' \})
\]

is an equivalence in \( \mathcal{C}_Y \). Without loss of generality, we may assume that there exists an element \( j \in I \) such that \( \alpha_i \) is an equivalence for \( i \neq j \), and that \( C_j' = \tau_{\leq k} C_j \). We have a fiber sequence

\[
C_j'[k + 1] \to C_j \to C_j'
\]

for some \( C_j'' \in (\mathcal{C}_X)_{\geq 0} \). Let \( C_i'' = C_i \) for \( i \neq j \). Since \( \otimes_\phi \) is exact in each variable, we conclude that there is a fiber sequence

\[
\otimes_\phi (\{ C_i'' \}[k + 1] \to \otimes_\phi (\{ C_i \}) \to \otimes_\phi (\{ C_i' \}).
\]

Since our t-structures are assumed to be compatible with \( p \), the object \( \otimes_\phi (\{ C_i'' \}) \) belongs to \( (\mathcal{C}_Y)_{\geq 0} \), from which it follows that \( \tau_{\leq k} (\beta) \) is an equivalence.

**Proposition 2.2.1.9.** Let \( p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a be a coCartesian fibration of \( \infty \)-operads and suppose we are given a family of localization functors \( \{ L_X : \mathcal{C}_X \to \mathcal{C}_X \}_{X \in \mathcal{O}} \) which are compatible with the \( \mathcal{O} \)-monoidal structure on \( \mathcal{C} \). Let \( \mathcal{D} \) denote the collection of all objects of \( \mathcal{C} \) which lie in the image of some \( L_X \), and let \( \mathcal{D}^\otimes \) be defined as above. Then:

1. There exists a commutative diagram

\[
\begin{array}{ccc}
\mathcal{C}^\otimes & \xrightarrow{L^\otimes} & \mathcal{D}^\otimes \\
p \downarrow & & \downarrow \\
\mathcal{O}^\otimes & \xrightarrow{} & \mathcal{C}^\otimes \\
\end{array}
\]

and a natural transformation \( \alpha : \text{id}_{\mathcal{C}^\otimes} \to L^\otimes \) which exhibits \( L^\otimes \) as a left adjoint to the inclusion \( \mathcal{D}^\otimes \subseteq \mathcal{C}^\otimes \) and such that \( p(\alpha) \) is the identity natural transformation from \( p \) to itself.
(2) The restriction \( p|\mathcal{D}^\circ : \mathcal{D}^\circ \to \mathcal{N}(\mathcal{F}\mathcal{I}\mathcal{N}_n) \) is a coCartesian fibration of \( \infty \)-operads.

(3) The inclusion functor \( \mathcal{C}^\circ \subseteq \mathcal{C}^\circ \) is a map of \( \infty \)-operads and \( L^\circ : \mathcal{C}^\circ \to \mathcal{D}^\circ \) is a \( \Omega \)-monoidal functor.

**Example 2.2.1.10.** Let \( \mathcal{E} \) be a stable \( \infty \)-category equipped with a t-structure and a compatible symmetric monoidal structure, in the sense of Example 2.2.1.3. Applying Proposition 2.2.1.8, we deduce that the truncation functors \( \tau_{\leq n} : \mathcal{E}_{\geq 0} \to (\mathcal{E}_{\geq 0})_{\leq n} \) are compatible with the symmetric monoidal structure on \( \mathcal{E}_{\geq 0} \). Consequently, Proposition 2.2.1.9 implies that \( (\mathcal{E}_{\geq 0})_{\leq n} \) inherits the structure of a symmetric monoidal \( \infty \)-category. Taking \( n = 0 \), we deduce that the heart of \( \mathcal{E} \) inherits the structure of a symmetric monoidal category (in the sense of classical category theory).

The proof of Proposition 2.2.1.9 relies on the following observation:

**Lemma 2.2.1.11.** Let \( p : \mathcal{C} \to \mathcal{D} \) be a coCartesian fibration of \( \infty \)-categories. Let \( L : \mathcal{C} \to \mathcal{C} \) and \( L' : \mathcal{D} \to \mathcal{D} \) be localization functors, with essential images \( L \mathcal{C} \) and \( L' \mathcal{D} \). Suppose that \( L \) and \( L' \) are compatible in the following sense:

(i) The functor \( p \) restricts to a functor \( p' : L \mathcal{C} \to L' \mathcal{D} \).

(ii) If \( f \) is a morphism in \( \mathcal{C} \) such that \( Lf \) is an equivalence, then \( L'p(f) \) is an equivalence in \( \mathcal{D} \).

Then:

(1) The functor \( L \) carries p-coCartesian morphisms of \( \mathcal{C} \) to \( p' \)-coCartesian morphisms of \( L \mathcal{C} \).

(2) The functor \( p' \) is a coCartesian fibration.

**Proof.** Let \( f : X \to Y \) be a p-coCartesian morphism of \( \mathcal{C} \). We wish to prove that \( Lf \) is \( p' \)-coCartesian. According to Proposition T.2.4.4.3, it will suffice to show that for every \( Z' \in L \mathcal{C} \), the diagram of Kan complexes

\[
\begin{array}{ccc}
\mathcal{E}_{Lf/} \times_{\mathcal{C}} Z' & \longrightarrow & \mathcal{E}_{LX/} \times_{\mathcal{C}} Z' \\
\downarrow & & \downarrow \\
\mathcal{D}_{p(Lf)/} \times_{\mathcal{D}} p(Z') & \longrightarrow & \mathcal{D}_{p(LX)/} \times_{\mathcal{D}} p(Z')
\end{array}
\]

is homotopy Cartesian. Let \( Z' = LZ \). Since \( L^2 \simeq L \), we can assume without loss of generality that \( Z \in L \mathcal{C} \).

Since \( f \) is p-coCartesian, Proposition T.2.4.4.3 implies that the diagram

\[
\begin{array}{ccc}
\mathcal{E}_{f/} \times_{\mathcal{C}} Z & \longrightarrow & \mathcal{E}_{X/} \times_{\mathcal{C}} Z \\
\downarrow & & \downarrow \\
\mathcal{D}_{p(f)/} \times_{\mathcal{D}} p(Z) & \longrightarrow & \mathcal{D}_{p(X)/} \times_{\mathcal{D}} p(Z)
\end{array}
\]

is homotopy Cartesian. Choose a natural transformation \( \alpha : \text{id}_{\mathcal{C}} \to L \) which exhibits \( L \) as a localization functor. Then \( \alpha \) induces a natural transformation between the above diagrams. It will therefore suffice to show that each of the induced maps

\[
\begin{align*}
\mathcal{E}_{f/} \times_{\mathcal{C}} Z & \to \mathcal{E}_{Lf/} \times_{\mathcal{C}} LZ \\
\mathcal{E}_{X/} \times_{\mathcal{C}} Z & \to \mathcal{E}_{LX/} \times_{\mathcal{C}} LZ \\
\mathcal{D}_{p(f)/} \times_{\mathcal{D}} p(Z) & \to \mathcal{D}_{p(Lf)/} \times_{\mathcal{D}} p(LZ) \\
\mathcal{D}_{p(X)/} \times_{\mathcal{D}} p(Z) & \to \mathcal{D}_{p(LX)/} \times_{\mathcal{D}} p(LZ)
\end{align*}
\]

is a homotopy equivalence. For the first pair of maps, this follows from the fact that \( Z \in L \mathcal{C} \). For the second pair, we observe that (i) and (ii) imply that for every \( C \in \mathcal{C} \), the map \( p(\alpha(C)) : p(C) \to p(LC) \) is equivalent to the \( L' \)-localization \( p(C) \to L'p(C) \), and \( p(Z) \in L' \mathcal{D} \). This completes the proof of (1).

To prove (2), choose any object \( C \in L \mathcal{C} \) and a morphism \( f : p(C) \to D \) in \( L' \mathcal{D} \). Choose a p-coCartesian morphism \( \overline{f} : C \to \overline{D} \) in \( \mathcal{E} \). According to (1), the morphism \( L(\overline{f}) : LC \to LD \) is \( p' \)-coCartesian. We now use the fact that \( p' \) is a categorical fibration to lift the equivalence \( p(\alpha(\overline{f})) \) to an equivalence \( L(\overline{f}) \simeq \overline{f}' \), where \( \overline{f}' : C \to \overline{D}' \) is a \( p' \)-coCartesian morphism lifting \( f \). \( \square \)
2.2. CONSTRUCTIONS OF $\infty$-OPERADS

Proof of Proposition 2.2.1.9. We first prove (1). Let us say that a map $f : C \to D$ in $\mathcal{C}^\otimes$ is localizing if it induces a trivial Kan fibration

$$\mathcal{D}^\otimes \times \mathcal{C}^\otimes_f \to \mathcal{D}^\otimes \times \mathcal{C}^\otimes_{D^\otimes}.$$ 

Arguing as in the proof of Proposition 2.2.1.1, we see that $f$ is localizing if and only if, for every object $D' \in \mathcal{D}^\otimes$, composition with $f$ induces a homotopy equivalence $\text{Map}_{\mathcal{C}^\otimes}(D, D') \to \text{Map}_{\mathcal{C}^\otimes}(C, D')$. Suppose that $f$ lies in a fiber $\mathcal{C}^\otimes_X$ of $p$, and let $D' \in \mathcal{C}^\otimes_{D^\otimes}$. We have canonical maps

$$\text{Map}_{\mathcal{C}^\otimes}(D, D') \to \text{Map}_{\mathcal{C}^\otimes}(X, Y) \leftarrow \text{Map}_{\mathcal{C}^\otimes}(C, D')$$

and Proposition T.2.4.4.2 allows us to identify the homotopy fibers of these maps over a morphism $g : X \to Y$ in $\mathcal{O}^\otimes$ with $\text{Map}_{\mathcal{C}^\otimes_Y}(g_1 D, D')$ and $\text{Map}_{\mathcal{C}^\otimes_Y}(g C, D')$. It follows that $f$ is localizing in $\mathcal{C}^\otimes$ if and only if $g_1(f)$ is localizing in $\mathcal{C}^\otimes_Y$ for every map $g : X \to Y$ in $\mathcal{O}^\otimes$. Let $X \in \mathcal{O}^\otimes(n)$ and $Y \in \mathcal{O}^\otimes(m)$ correspond to sequences of objects $\{X_i\}_{1 \leq i \leq n}$ and $\{Y_j\}_{1 \leq j \leq m}$ in $\mathcal{O}$. Using the equivalence $\mathcal{C}^\otimes_Y \simeq \prod_{1 \leq j \leq m} \mathcal{C}^\otimes{Y_j}$, we see that it suffices to check this in the case $m = 1$. Invoking the assumption that the localization functors $\mathcal{C}^\otimes_Y \simeq \prod_{1 \leq j \leq m} \mathcal{C}^\otimes{Y_j}$ are compatible with the $\mathcal{O}$-monoidal structure on $\mathcal{C}^\otimes$, we see that $f$ is localizing if and only if it induces a $L_X$-localizing morphism in $\mathcal{C}^\otimes_X$, for $1 \leq i \leq n$.

We now argue as in the proof of Proposition 2.2.1.1. To prove (1), we need to construct a commutative diagram

$$\begin{array}{ccc}
\mathcal{C}^\otimes \times \Delta^1 & \xrightarrow{\alpha} & \mathcal{C}^\otimes \\
\downarrow \alpha \downarrow \downarrow \downarrow \alpha & & \downarrow \downarrow \downarrow \downarrow \alpha \\
\mathcal{N}(\text{Fin}^\ast) & \xrightarrow{p} & \mathcal{O}^\otimes \\
\end{array}$$

with $\alpha|\mathcal{C}^\otimes \times \{0\}$ equal to the identity, and having the property that, for every object $C \in \mathcal{C}^\otimes$, the restriction $\alpha|\{C\} \times \Delta^1$ is localizing. For this, we construct $\alpha$ one simplex at a time. To define $\alpha$ on a vertex $C \in \mathcal{C}^\otimes_X$ for $X \in \mathcal{O}^\otimes(n)$, we choose a morphism $f : C \to C'$ corresponding to the localization morphisms $C_i \to L_X C_i$ under the equivalence $\mathcal{C}^\otimes_X \simeq \prod_{1 \leq i \leq n} \mathcal{C}^\otimes_X$, and apply the argument above. For simplices of higher dimension, we need to solve extensions problems of the form

$$(\partial \Delta^n \times \Delta^1) \coprod_{\partial \Delta^n \times \{0\}} (\Delta^n \times \{0\}) \xrightarrow{\alpha_0} \mathcal{C}^\otimes,$$

where $n > 0$ and $\alpha_0$ carries each of the edges $\{i\} \times \Delta^1$ to a localizing morphism in $\mathcal{C}^\otimes$. We now observe that $\Delta^n \times \Delta^1$ admits a filtration

$$X_0 \subseteq X_1 \subseteq \ldots \subseteq X_n \subseteq X_{n+1} = \Delta^n \times \Delta^1,$$

where $X_0 = (\partial \Delta^n \times \Delta^1) \coprod_{\partial \Delta^n \times \{0\}} (\Delta^n \times \{0\})$ and there exist pushout diagrams

$$\begin{array}{ccc}
\Lambda^{n+1}_{n-i} & \xrightarrow{} & \Delta^{n+1} \\
\downarrow & & \downarrow \\
X_i & \xrightarrow{} & X_{i+1} \\
\end{array}$$

We now argue, by induction on $i$, that the map $\alpha_0$ admits an extension to $X_i$ (compatible with the projection $p$). For $i \leq n$, this follows from the fact that $p$ is an inner fibration. For $i = n + 1$, it follows from the definition of a localizing morphism. This completes the proof of (1).

Lemma 2.2.1.11 implies that $p' = p|\mathcal{D}^\otimes$ is a coCartesian fibration. It follows immediately from the definition that for every object $X \in \mathcal{O}^\otimes(n)$ corresponding to $\{X_i \in \mathcal{O}\}_{1 \leq i \leq m}$, the equivalence $\mathcal{C}^\otimes_X \simeq \prod_{1 \leq i \leq m} \mathcal{C}^\otimes_X$,
restricts to an equivalence $\mathcal{D}_{X}^{\otimes} \simeq \prod_{1 \leq i \leq m} \mathcal{D}_{X_i}$. This proves that $p^{' \otimes} : \mathcal{D}_{X}^{\otimes} \to \mathcal{O}_{Y}^{\otimes}$ is a coCartesian fibration of $\infty$-operads and that the inclusion $\mathcal{D}_{X}^{\otimes} \subseteq \mathcal{O}_{Y}^{\otimes}$ is a map of $\infty$-operads. Lemma 2.2.1.11 implies that $L_{X}^{\otimes}$ carries $p$-coCartesian edges to $p^{' \otimes}$-coCartesian edges and is therefore a $\otimes$-monoidal functor. \hfill \square

2.2.2 Slicing $\infty$-Operads

Let $\mathcal{C}$ be a symmetric monoidal category and let $A$ be a commutative algebra object of $\mathcal{C}$. Then the overcategory $\mathcal{C}/A$ inherits the structure of a symmetric monoidal category: the tensor product of a map $X \to A$ with a map $Y \to A$ is given by the composition

$$X \otimes Y \to A \otimes A \overset{m}{\to} A,$$

where $m$ denotes the multiplication on $A$. Our goal in this section is to establish an $\infty$-categorical analogue of this observation (and a weaker result concerning undercategories). Before we can state our result, we need to introduce a bit of notation.

**Definition 2.2.2.1.** Let $q : X \to S$ be a map of simplicial sets, and suppose we are given a commutative diagram

$$\begin{array}{ccc}
X & \xrightarrow{p} & \mathcal{S} \\
\downarrow{q} & & \downarrow{q} \\
S \times K & \xrightarrow{p} & S.
\end{array}$$

We define a simplicial set $X_{ps/}$ equipped with a map $q' : X_{ps/} \to S$ so that the following universal property is satisfied: for every map of simplicial sets $Y \to S$, there is a canonical bijection of $\text{Fun}_S(Y, X_{ps/})$ with the collection of commutative diagrams

$$\begin{array}{ccc}
Y \times K & \xrightarrow{p} & Y \times K^p \xrightarrow{q} Y \\
\downarrow & & \downarrow \\
S \times K & \xrightarrow{p} & X \xrightarrow{q} S.
\end{array}$$

Similarly, we define a map of simplicial sets $X_{ps} \to S$ so that $\text{Fun}_S(Y, X_{ps})$ is in bijection with the set of diagrams

$$\begin{array}{ccc}
Y \times K & \xrightarrow{p} & Y \times K^q \xrightarrow{q} Y \\
\downarrow & & \downarrow \\
S \times K & \xrightarrow{p} & X \xrightarrow{q} S.
\end{array}$$

**Remark 2.2.2.** If $S$ consists of a single point, then $X_{ps/}$ and $X_{ps}$ coincide with the usual overcategory and undercategory constructions $X_{p/}$ and $X_{p}$, respectively. In general, the fiber of the morphism $X_{ps/} \to S$ over a vertex $s \in S$ can be identified with $(X_{s})_{ps/}$, where $X_{s} = X \times_{S} \{s\}$ and $p_{s} : K \to X_{s}$ is the induced map; similarly, we can identify $X_{ps} \times_{S} \{s\}$ with $(X_{s})_{ps}$.

**Notation 2.2.2.3.** Let $q : \mathcal{C}^{\otimes} \to \mathcal{O}_{Y}^{\otimes}$ be a fibration of $\infty$-operads, and let $p : K \to \text{Alg}_{/ \mathcal{C}}$ be a diagram. We let $\mathcal{C}_{p_{A}}^{\otimes}$ and $\mathcal{C}_{/ \mathcal{C}}^{\otimes}$ denote the simplicial sets $(\mathcal{C}_{p_{\mathcal{C}}}/)_{\mathcal{O}_{A}^{\otimes}}$ and $(\mathcal{C}_{/ \mathcal{C}})^{\otimes}_{\mathcal{O}_{A}^{\otimes}}$ described in Definition 2.2.2.1.

In the special case where $K = \Delta^{0}$, the diagram $p$ is simply given by a $\mathcal{O}$-algebra object $A \in \text{Alg}_{/ \mathcal{C}}$; in this case, we will denote $\mathcal{C}_{p_{A}}^{\otimes}$ and $\mathcal{C}_{/ \mathcal{C}}^{\otimes}$ by $\mathcal{C}_{/ \mathcal{A}_{\mathcal{O}}}^{\otimes}$ and $\mathcal{C}_{/ \mathcal{A}_{\mathcal{O}}}^{\otimes}$, respectively.

We can now state the main result of this section.

**Theorem 2.2.2.4.** Let $q : \mathcal{C}^{\otimes} \to \mathcal{O}_{Y}^{\otimes}$ be a fibration of $\infty$-operads, and let $p : K \to \text{Alg}_{/ \mathcal{C}}(\mathcal{C})$ be a diagram.

Then:
2.2. CONSTRUCTIONS OF ∞-OPERADS

(1) The maps \( C^\otimes_{p_{0}/} \to \Omega^\otimes \to C_{p_{0}/}^\otimes \) are fibrations of ∞-operads.

(2) A morphism in \( C^\otimes_{p_{0}/} \) is inert if and only if its image in \( C^\otimes \) is inert; similarly, a morphism in \( C_{p_{0}/}^\otimes \) is inert if and only if its image in \( C^\otimes \) is inert.

(3) If \( q \) is a coCartesian fibration of ∞-operads, then \( q'' \) is a coCartesian fibration of ∞-operads. If, in addition, \( p(k) : \Omega^\otimes \to C^\otimes \) is a \( \Omega \)-monoidal functor for each vertex \( k \in K \), then \( q' \) is also a coCartesian fibration of ∞-operads.

Remark 2.2.2.5. In the special case where \( \Omega^\otimes \) is the commutative ∞-operad and \( K = \Delta^0 \), we can state Theorem 2.2.2.4 more informally as follows: let \( C^\otimes \) be an ∞-operad equipped with a commutative algebra object \( A \in \text{CAlg}(C) \). Then the ∞-categories \( C^\otimes_{A/} \) and \( C_{A/}^\otimes \) can be regarded as the underlying ∞-categories of ∞-operads \( C^\otimes_{A_{\Delta^0}/} \) and \( C^\otimes_{A_{\Delta^0}}_{/} \). Moreover, if \( C \) is a symmetric monoidal ∞-category, then \( C_{A/}^\otimes \) is a symmetric monoidal ∞-category; the same result holds for \( C^\otimes_{A/} \) if we assume that \( A \) is a trivial algebra in the sense of Definition 3.2.1.7.

The remainder of this section is devoted to the proof of Theorem 2.2.2.4. We will need a few lemmas.

Lemma 2.2.2.6. Suppose we are given a diagram of simplicial sets

\[
\begin{array}{ccc}
X & \xrightarrow{q} & S \\
\downarrow^{p} & & \downarrow^{q} \\
S \times K & \xrightarrow{q'} & S
\end{array}
\]

where \( q \) is an inner fibration, and let \( q' : X_{ps/} \to S \) be the induced map. Then \( q' \) is an inner fibration. Similarly, if \( q \) is a categorical fibration, then \( q' \) is a categorical fibration.

Proof. We will prove the assertion regarding inner fibrations; the case of categorical fibrations is handled similarly. We wish to show that every lifting problem of the form

\[
\begin{array}{ccc}
A & \xrightarrow{j} & X_{ps/} \\
\downarrow^{i} & & \downarrow^{q'} \\
B & \xrightarrow{q'} & S
\end{array}
\]

admits a solution, provided that \( j \) is inner anodyne. Unwinding the definitions, we arrive at an equivalent lifting problem

\[
\begin{array}{ccc}
(A \times K^\circ) \coprod_{A \times K} (B \times K) & \xrightarrow{j'} & X \\
\downarrow^{j'} & & \downarrow^{q} \\
B \times K^\circ & \xrightarrow{q} & S
\end{array}
\]

which admits a solution by virtue of the fact that \( q \) is an inner fibration and \( j' \) is inner anodyne (Corollary T.2.3.2.4).

Lemma 2.2.2.7. Let \( q : X \to S \) be an inner fibration of simplicial sets and let \( K \) and \( Y \) be simplicial sets. Suppose that \( \overline{h} : K \times Y^\circ \to X \) is a map such that, for each \( k \in K \), the induced map \( \{k\} \times Y^\circ \to X \) is a \( q \)-colimit diagram. Let \( h = \overline{h}|K \times Y \). Then the map

\[
X_{\overline{h}/} \to X_{h/} \times_{S_{h/}} S_{qK/}
\]

is a trivial Kan fibration.
Proof. We will prove more generally that if \( K_0 \subseteq K \) is a simplicial subset and \( \mathcal{F}_0 = \mathcal{F}(K \times Y) \coprod_{K_0 \times Y}(K \times Y^\circ) \), then the induced map \( \theta : X_{\mathcal{F}_0} \to X_{\mathcal{F}_0} \times S_{\partial_\mathcal{F}/} S_{\partial_\mathcal{F}/} \) is a trivial Kan fibration. Working simplex-by-simplex, we can reduce to the case where \( K = \partial \Delta^n \) and \( K' = \partial \Delta^n \). Let us identify \( Y \star \Delta^n \) with the full simplicial subset of \( Y^\circ \times \Delta^n \) spanned by \( \Delta^n \) and \( Y^\circ \times \{0\} \). Let \( \mathcal{F} = \mathcal{F}(Y \star \Delta^n) \), and let \( g = \mathcal{F}Y \star \partial \Delta^n \). Then \( \theta \) is a pullback of the map

\[
\theta' : X_{\mathcal{F}/} \to X_{\mathcal{F}/} \times S_{\partial_{\mathcal{F}/}} S_{\partial_{\mathcal{F}/}}.
\]

It will now suffice to show that \( \theta' \) has the right lifting property with respect to every inclusion \( \partial \Delta^m \subseteq \Delta^n \). Unwinding the definition, this is equivalent to solving a lifting problem of the form

\[
\begin{array}{ccc}
Y \star \partial \Delta^{n+m+1} & \rightarrow & X \\
\downarrow & & \downarrow q \\
Y \star \Delta^{n+m+1} & \rightarrow & S.
\end{array}
\]

This lifting problem admits a solution by virtue of our assumption that \( \mathcal{F}[\{0\} \times Y^\circ] \) is a \( q \)-colimit diagram. \( \square \)

Lemma 2.2.2.8. Let

\[
\begin{array}{ccc}
& & X \\
& p \swarrow & \\
S \times K & \rightarrow & S \\
& q \searrow & \\
& & S
\end{array}
\]

be a diagram of simplicial sets, where \( q \) is an inner fibration, let \( q' : X^{ps/} \to S \) be the induced map, and suppose we are given a commutative diagram

\[
\begin{array}{ccc}
Y & \xrightarrow{f} & X^{ps/} \\
\downarrow & \searrow & \downarrow q' \\
Y^\circ & \xrightarrow{g} & S
\end{array}
\]

satisfying the following conditions:

(i) For each vertex \( k \in K \), the diagram

\[
Y^\circ \xrightarrow{\theta} S \simeq S \times \{k\} \rightarrow S \times K \xrightarrow{p} X
\]

is a \( q \)-colimit diagram.

(ii) The composite map \( Y \xrightarrow{f} X^{ps/} \to X \) can be extended to a \( q \)-colimit diagram \( Y^\circ \to X \) lying over \( g \).

Then:

(1) Let \( f : Y^\circ \to X^{ps/} \) be a map rendering the diagram commutative. Then \( f \) is a \( q' \)-colimit diagram if and only if the composite map \( Y^\circ \xrightarrow{\mathcal{F}} X^{ps/} \to X \) is a \( q \)-colimit diagram.

(2) There exists a map \( \mathcal{F} \) satisfying the equivalent conditions of (1).

Proof. Let \( Z \) be the full simplicial subset of \( K^\circ \times Y^\circ \) obtained by removing the final object, so we have a canonical isomorphism \( Z^\circ \simeq K^\circ \times Y^\circ \). The maps \( f \) and \( g \) determine a diagram \( h : Z \to X \). We claim that \( h \) can be extended to a \( q \)-colimit diagram \( \mathcal{F} : Z^\circ \to X \) lying over the map \( Z^\circ \to Y^\circ \xrightarrow{\theta} S \). To prove this, let \( h_0 = h|K^\circ \times Y \), \( h_1 = h|K \times Y^\circ \), and \( h_2 = h|K \times Y \). Using (i) we deduce that the map \( \theta : X_{h_0} \to X_{h_1} \times S_{\phi_0} S_{\phi_1} \) is a trivial Kan fibration (Lemma 2.2.2.7). The map \( X_{h_1} \to X_{h_0} \times S_{\phi_0} S_{\phi_1} \) is a pullback of \( \theta \), and therefore also a trivial Kan fibration. Consequently, to show that \( h \) admits a \( q \)-colimit
diagram compatible with $g$, it suffices to show that $h_0$ admits a $q$-colimit diagram compatible with $g$. Since the inclusion $Y \hookrightarrow K^\circ \times Y$ is left cofinal, this follows immediately from (ii). This proves the existence of $\overline{h}$: moreover, it shows that an arbitrary extension $\overline{h}$ of $h$ (compatible with $g$) is a $p$-colimit diagram if and only if it restricts to a $p$-colimit diagram $Y^n \to Z$.

The map $\overline{h}$ determines an extension $\overline{f} : Y^\circ \to X_{ps/}$ of $f$. We will show that $\overline{f}$ is a $q'$-colimit diagram. This will prove the “if” direction of (1) and (2); the “only if” direction of (1) will then follow from the uniqueness properties of $q'$-colimit diagrams.

We wish to show that every lifting problem of the form

$$
\begin{array}{c}
Y \star \Delta^n \xrightarrow{f} X_{ps/} \\
\downarrow \\
Y \star \Delta^n \\
\downarrow \\
S
\end{array}
$$

admits a solution, provided that $n > 0$ and $F|Y \star \{0\}$ coincides with $\overline{f}$. This is equivalent to a lifting problem of the form

$$
\begin{array}{c}
((Y \star \partial \Delta^n) \times K^\circ) \coprod_{(Y \star \Delta^n) \times K} (Y \star \Delta^n) \xrightarrow{j} X \\
\downarrow \\
(Y \star \Delta^n) \times K^\circ \\
\downarrow \\
S
\end{array}
$$

It now suffices to observe that the map $j$ is a pushout of the inclusion $Z \star \partial \Delta^n \hookrightarrow Z \star \Delta^n$, so the desired lifting problem can be solved by virtue of our assumption that $\overline{h}$ is a $q$-colimit diagram.

The following result is formally similar to Lemma 2.2.2.8 but requires a slightly different proof:

**Lemma 2.2.2.9.** Let

$$
\begin{array}{c}
X \\
p \\
\downarrow q \\
S \times K \\
\downarrow \\
S
\end{array}
$$

be a diagram of simplicial sets, where $q$ is an inner fibration, let $q' : X_{ps/} \to S$ be the induced map, and suppose we are given a commutative diagram

$$
\begin{array}{c}
Y \\
f \\
\downarrow \\
X_{ps/}
\end{array}
\quad
\begin{array}{c}
Y^\circ \\
g \\
\downarrow \\
S
\end{array}
\quad
\begin{array}{c}
X \\
p \\
\downarrow q \\
S \times K \\
\downarrow \\
S
\end{array}
$$

satisfying the following condition:

(\ast) The composite map $Y \xrightarrow{f} X_{ps/} \to X$ can be extended to a $q$-limit diagram $g' : Y^\circ \to X$ lying over $g$.

Then:

(1) Let $\overline{f} : Y^\circ \to X_{ps/}$ be a map rendering the diagram commutative. Then $\overline{f}$ is a $q'$-limit diagram if and only if the composite map $Y^\circ \xrightarrow{\overline{f}} X_{ps/} \to X$ is a $q$-limit diagram.

(2) There exists a map $\overline{f}$ satisfying the equivalent conditions of (1).
Proof. Let \( v \) be the cone point of \( K^\partial \) and \( v' \) the cone point of \( Y^q \). Let \( Z \) be the full subcategory of \( K^\partial \times Y^q \) obtained by removing the vertex \((v, v')\). The maps \( f \) and \( g \) determine a map \( h : Z \to X \). Choose any map \( g' \) as in (i), and let \( g'_0 = g'|Y \). We claim that there exists an extension \( \overline{h} : K^\partial \times Y^q \to X \) of \( h \) which is compatible with \( g \), such that \( \overline{h}(\{v\} \times Y^q) = g' \). Unwinding the definitions, we see that providing such a map \( \overline{h} \) is equivalent to solving a lifting problem of the form

\[
\begin{array}{ccc}
\emptyset & \to & X_{g'} \\
\downarrow & & \downarrow \\
K & \to & X_{g'_0} \times S_{/g'_0} S_{/g},
\end{array}
\]

which is possible since the left vertical map is a trivial Kan fibration (since \( g' \) is a \( q \)-limit diagram).

The map \( \overline{h} \) determines a diagram \( \overline{f} : Y^q \to X_{p/} \). We will prove that \( \overline{f} \) is a \( q' \)-limit diagram. This will prove the “if” direction of (1) and (2); the “only if” direction of (1) will then follow from the uniqueness properties of \( q \)-limit diagrams.

To show that \( \overline{f} \) is a \( q \)-limit diagram, we must show that every lifting problem of the form

\[
\begin{array}{ccc}
\partial \Delta^n \ast Y & \to & X_{p/} \\
\downarrow & \swarrow & \downarrow \overline{f} \\
\Delta^n \ast Y & \to & S
\end{array}
\]

admits a solution, provided that \( n > 0 \) and \( F|\{n\} \ast Y = \overline{f} \). Unwinding the definitions, we obtain an equivalent lifting problem

\[
\begin{array}{ccc}
(\partial \Delta^n \ast Y) \times K^\partial & \longleftarrow & X \\
\downarrow & & \downarrow j \\
(\Delta^n \ast Y) \times K^\partial & \longleftarrow & S
\end{array}
\]

It now suffices to observe that \( j \) is a pushout of the inclusion \( K \ast \partial \Delta^n \ast Y \to K \ast \Delta^n \ast Y \), so that the desired extension exists because \( \overline{h}(\{v\} \times Y^q) = g' \) is a \( q \)-limit diagram. \( \square \)

Proof of Theorem 2.2.2.4. We will prove (1), (2), and (3) for the simplicial set \( \mathcal{C}_{p/o}^\otimes \); the analogous assertions for \( \mathcal{C}_{p/o}^\otimes \) will follow by the same reasoning. We first observe that \( q' \) is a categorical fibration (Lemma 2.2.2.6). Let \( \overline{X} \in \mathcal{C}_{p/o}^\otimes \), and suppose we are given an inert morphism \( \alpha : q(\overline{X}) \to Y \) in \( \mathcal{O}^\otimes \); we wish to show that there exists a \( q' \)-coCartesian morphism \( \overline{X} \to \overline{Y} \) in \( \mathcal{C}_{p/o}^\otimes \) lifting \( \alpha \). This follows immediately from Lemma 2.2.2.8.

Suppose next that we are given an object \( X \in \mathcal{O}^\otimes \) lying over \( \langle n \rangle \in \mathit{Fin}_* \), and a collection of inert morphisms \( \alpha^i : X \to X_i \) lying over \( \rho^i : \langle n \rangle \to \langle 1 \rangle \) for \( 1 \leq i \leq n \). We wish to prove that the maps \( \alpha^i \) induce an equivalence

\[
\theta : (\mathcal{C}_{p/o}^\otimes)_X \cong \prod_{1 \leq i \leq n} (\mathcal{C}_{p/o}^\otimes)_{X_i}.
\]

Let \( p_X : K \to \mathcal{C}_{X}^\otimes \) be the map induced by \( p \), and define maps \( p_X^i : K \to \mathcal{C}_{X_i} \), similarly. We observe that \( p_{X_i} \) can be identified with the composition of \( p_X \) with \( \alpha^i : \mathcal{C}_{X} \to \mathcal{C}_{X_i} \). Since \( q \) is a fibration of \( \infty \)-operads, we have an equivalence of \( \infty \)-categories

\[
\mathcal{C}_{X}^\otimes \to \prod_{1 \leq i \leq n} \mathcal{C}_{X_i}.
\]

Passing to the \( \infty \)-categories of objects under \( p \), we deduce that \( \theta \) is also an equivalence.

Now suppose that \( X \) is as above, that \( \overline{X} \in \mathcal{C}_{p/o}^\otimes \) is a preimage of \( X \), and that we are given \( q' \)-coCartesian morphisms \( \overline{X} \to \overline{X}_i \) lying over the maps \( \alpha^i \). We wish to show that the induced map \( \delta : \langle n \rangle^< \mathcal{C}_{p/o}^\otimes \) is a

$q'$-limit diagram. This follows from Lemma 2.2.2.9, since the image of $\delta$ in $\mathcal{C}^\otimes$ is a $q'$-limit diagram. This completes the proof of (1). Moreover, our characterization of $q'$-coCartesian morphisms immediately implies (2). Assertion (3) follows immediately from Lemma 2.2.2.8.

### 2.2.3 Coproducts of $\infty$-Operads

Let $\mathbf{Op}_\infty$ denote the $\infty$-category of $\infty$-operads (Definition 2.1.4.1). Because $\mathbf{Op}_\infty$ can be realized as underlying $\infty$-category of the combinatorial simplicial model category $\mathcal{P}\mathbf{Op}_\infty$ of $\infty$-preoperads, it admits all small limits and colimits (Corollary T.4.2.4.8). The limit of a diagram $\sigma$ in $\mathbf{Op}_\infty$ can usually be described fairly explicitly: namely, choose an injectively fibrant diagram $\sigma'$ in $\mathcal{P}\mathbf{Op}_\infty$ representing $\sigma$, and then take the limit of $\sigma'$ in the ordinary category of $\infty$-preoperads. The case of colimits is more difficult: we can apply the same procedure to construct an $\infty$-preoperad which represents $\lim_{\infty}(\sigma)$, but this representative will generally not be fibrant and the process of “fibrant replacement” is fairly inexplicit. Our goal in this section is to give a more direct construction of colimits in a special case: namely, the case of coproducts. We can summarize our main results as follows: for every pair of $\infty$-operads $\mathcal{C}^\otimes$ and $\mathcal{D}^\otimes$, we can explicitly construct a new $\infty$-operad $\mathcal{C}^\otimes \boxplus \mathcal{D}^\otimes$. This $\infty$-category comes equipped with fully faithful embeddings

$$\mathcal{C}^\otimes \to \mathcal{C}^\otimes \boxplus \mathcal{D}^\otimes \to \mathcal{D}^\otimes$$

(well-defined up to homotopy) which exhibit $\mathcal{C}^\otimes \boxplus \mathcal{D}^\otimes$ as a coproduct of $\mathcal{C}^\otimes$ and $\mathcal{D}^\otimes$ in the $\infty$-category $\mathbf{Op}_\infty$ (Theorem 2.2.3.6), and exhibit the underlying $\infty$-category of $\mathcal{C}^\otimes \boxplus \mathcal{D}^\otimes$ as a coproduct of $\mathcal{C}$ and $\mathcal{D}$ in $\mathcal{C}\mathbf{at}_\infty$.

Before describing the construction of $\mathcal{C}^\otimes \boxplus \mathcal{D}^\otimes$, we need to establish some notation.

**Notation 2.2.3.1.** Given an object $\langle n \rangle \in \mathbf{Fin}_*$ and a subset $S \subseteq \langle n \rangle$ which contains the base point, there is a unique integer $k$ and bijection $\langle k \rangle \simeq S$ whose restriction to $\langle k \rangle^\circ$ is order-preserving; we will denote the corresponding object of $\mathbf{Fin}_*$ by $[S]$.

**Definition 2.2.3.2.** We define a category $\text{Sub}$ as follows:

1. The objects of $\text{Sub}$ are triples $\langle n \rangle, S, T$ where $\langle n \rangle \in \mathbf{Fin}_*$, $S$ and $T$ are subsets of $\langle n \rangle$ such that $S \cup T = \langle n \rangle$ and $S \cap T = \{ * \}$.

2. A morphism from $\langle (n), S, T \rangle$ to $\langle (n'), S', T' \rangle$ in $\text{Sub}$ is a morphism $f : \langle n \rangle \to \langle n' \rangle$ in $\mathbf{Fin}_*$ such that $f(S) \subseteq S'$ and $f(T) \subseteq T'$.

There is an evident triple of functors $\pi, \pi_-, \pi_+ : \text{Sub} \to \mathbf{Fin}_*$ given by the formulas

$$\pi_- (\langle n \rangle, S, T) = [S] \quad \pi(\langle n \rangle, S, T) = \langle n \rangle \quad \pi_+ (\langle n \rangle, S, T) = [T].$$

**Construction 2.2.3.3.** For any pair of simplicial sets $\mathcal{C}^\otimes$ and $\mathcal{D}^\otimes$ equipped with maps $\mathcal{C}^\otimes \to N(\mathbf{Fin}_*) \leftarrow \mathcal{D}^\otimes$, we define a new simplicial set $\mathcal{C}^\otimes \boxplus \mathcal{D}^\otimes$ so that we have a pullback diagram

$$
\begin{array}{ccc}
\mathcal{C}^\otimes \boxplus \mathcal{D}^\otimes & \to & \mathcal{C}^\otimes \times \mathcal{D}^\otimes \\
\downarrow & & \downarrow \\
N(\text{Sub}) & \xrightarrow{\pi_- \times \pi_+} & N(\mathbf{Fin}_*) \times N(\mathbf{Fin}_*)
\end{array}
$$

We regard $\mathcal{C}^\otimes \boxplus \mathcal{D}^\otimes$ as equipped with a map to $N(\mathbf{Fin}_*)$, given by the composition

$$\mathcal{C}^\otimes \boxplus \mathcal{D}^\otimes \to N(\text{Sub}) \xrightarrow{\pi_-} N(\mathbf{Fin}_*).$$

**Remark 2.2.3.4.** The product functor $(\pi_- \times \pi_+) : \text{Sub} \to \mathbf{Fin}_* \times \mathbf{Fin}_*$ is an equivalence of categories. Consequently, $\mathcal{C}^\otimes \boxplus \mathcal{D}^\otimes$ is equivalent (as an $\infty$-category) to the product $\mathcal{C}^\otimes \times \mathcal{D}^\otimes$. However, it is slightly better behaved in the following sense: the composite map

$$\mathcal{C}^\otimes \boxplus \mathcal{D}^\otimes \to N(\text{Sub}) \to N(\mathbf{Fin}_*)$$
is a categorical fibration, since it is the composition of a pullback of the categorical fibration $\mathcal{C} \otimes \mathcal{D} \rightarrow N(\text{Fin}_*) \times N(\text{Fin}_*)$ with the categorical fibration $N(\text{Sub}) \rightarrow N(\text{Fin}_*)$.

The main results of this section can now be stated as follows:

**Proposition 2.2.3.5.** Let $\mathcal{C} \otimes$ and $\mathcal{D} \otimes$ be $\infty$-operads. Then $\mathcal{C} \otimes \mathcal{D} \otimes$ is an $\infty$-operad.

**Theorem 2.2.3.6.** Let $\mathcal{C} \otimes$ and $\mathcal{D} \otimes$ be $\infty$-operads. We let $(\mathcal{C} \otimes \mathcal{D} \otimes)_-$ denote the full subcategory spanned by those objects whose image in $\text{Sub}$ has the form $(\langle n \rangle, \langle n \rangle, \{\ast\})$, and let $(\mathcal{C} \otimes \mathcal{D} \otimes)_+$ denote the full subcategory spanned by those objects whose image in $\text{Sub}$ has the form $(\langle n \rangle, \{\ast\}, \langle n \rangle)$. Then:

1. The projection maps $(\mathcal{C} \otimes \mathcal{D} \otimes)_- \rightarrow \mathcal{C} \otimes$ and $(\mathcal{C} \otimes \mathcal{D} \otimes)_+ \rightarrow \mathcal{D} \otimes$ are trivial Kan fibrations.
2. The map $\mathcal{C} \otimes \mathcal{D} \otimes \rightarrow N(\text{Fin}_*)$ exhibits both $(\mathcal{C} \otimes \mathcal{D} \otimes)_-$ and $(\mathcal{C} \otimes \mathcal{D} \otimes)_+$ as $\infty$-operads.
3. For any $\infty$-operad $\mathcal{E}$, the inclusions

   $$((\mathcal{C} \otimes \mathcal{D} \otimes)_- \hookrightarrow \mathcal{C} \otimes \otimes \mathcal{D} \otimes \hookrightarrow (\mathcal{C} \otimes \mathcal{D} \otimes)_+)$$

   induce an equivalence of $\infty$-categories

   $$\text{Fun}^{\text{lax}}(\mathcal{C} \otimes \mathcal{D} \otimes, \mathcal{E}) \rightarrow \text{Fun}^{\text{lax}}((\mathcal{C} \otimes \mathcal{D} \otimes)_-, \mathcal{E}) \times \text{Fun}^{\text{lax}}((\mathcal{C} \otimes \mathcal{D} \otimes)_+, \mathcal{E});$$

   here we let $\text{Fun}^{\text{lax}}(\mathcal{C} \otimes \mathcal{D} \otimes, \mathcal{E})$ denote the $\infty$-category $\text{Alg}_\mathcal{O}(\mathcal{O}')$ of $\infty$-operad maps from $\mathcal{O} \otimes$ to $\mathcal{O}' \otimes$, for any pair of $\infty$-operads $\mathcal{O} \otimes$, $\mathcal{O}' \otimes$. In particular, $i$ and $j$ exhibit $\mathcal{C} \otimes \mathcal{D} \otimes$ as a coproduct of $(\mathcal{C} \otimes \mathcal{D} \otimes)_- \simeq \mathcal{C} \otimes$ and $(\mathcal{C} \otimes \mathcal{D} \otimes)_+ \simeq \mathcal{D} \otimes$ in the $\infty$-category $\text{Op}_\infty$.

**Remark 2.2.3.7.** The operation $\boxtimes$ of Construction 2.2.3.3 is commutative and associative up to coherent isomorphism, and determines a symmetric monoidal structure on the category $(\text{Set}_{\Delta})_{/N(\text{Fin}_*)}$ of simplicial sets $X$ endowed with a map $X \rightarrow N(\text{Fin}_*)$. This restricts to a symmetric monoidal structure on the (ordinary) category of $\infty$-operads and maps of $\infty$-operads.

**Remark 2.2.3.8.** We can informally summarize Theorem 2.2.3.6 as follows: for every triple of $\infty$-operads $\mathcal{O}_-, \mathcal{O}_+, \mathcal{E}_\otimes$, we can have a canonical equivalence of $\infty$-categories

$$\text{Alg}_{\mathcal{O}_-}(\mathcal{E}) \rightarrow \text{Alg}_{\mathcal{O}_+}(\mathcal{E}) \times \text{Alg}_{\mathcal{O}_+}(\mathcal{E}),$$

where $\mathcal{O} \otimes = \mathcal{O}_- \boxtimes \mathcal{O}_+ \boxtimes \mathcal{O}_+$.  

**Proof of Proposition 2.2.3.5.** Let $X$ be an object of $(\mathcal{C} \otimes \mathcal{D} \otimes)_{(n)}$, given by a quintuple $(\langle n \rangle, S, T, C, D)$ where $(\langle n \rangle, S, T) \subset \text{Sub}$, $C \subset \mathcal{E}^{\{s\}}$, and $D \subset \mathcal{D}^{\{t\}}$. Suppose we are given an inert map $\alpha : (n) \rightarrow (n')$ in $\mathcal{S}_\text{Fin}_*$. Let $S' = \alpha(S)$ and $T' = \alpha(T)$. Then $\alpha$ induces inert morphisms $\alpha_- : [S] \rightarrow [S']$ and $\alpha_+ : [T] \rightarrow [T']$. Choose an inert morphism $\alpha_+ : C \rightarrow C'$ in $\mathcal{E}^{\otimes}$ lifting $\alpha_-$. Then our maps exhibit an inert morphism $\alpha_+ : \mathcal{C} \rightarrow \mathcal{C}'$ such that $\alpha(\mathcal{C}) \subset \mathcal{C}'$, and an inert morphism $f_+ : D \rightarrow D'$ in $\mathcal{D}^{\otimes}$ lifting $\alpha_+$. These maps together determine a morphism $f : (\langle n \rangle, S, T, C, D) \rightarrow (\langle n' \rangle, S', T', C', D')$. Since $(f_-, f_+)$ is coCartesian with respect to the projection $\mathcal{E}^{\otimes} \times \mathcal{D}^{\otimes} \rightarrow N(\mathcal{S}_\text{Fin}_*) \times N(\mathcal{S}_\text{Fin}_*)$, the map $f$ is $p$-coCartesian, where $p$ denotes the map $\mathcal{E} \otimes \mathcal{D} \otimes \rightarrow N(\mathcal{S}_\text{Fin}_*)$. Let $\pi : N(\text{Sub}) \rightarrow N(\mathcal{S}_\text{Fin}_*)$ be as in Definition 2.2.3.2. It is easy to see that $\pi(f)$ is $p$-coCartesian, so that $f$ is $(\pi \circ p)$-coCartesian by virtue of Proposition T.2.4.1.3.

Choose $(\pi \circ p)$-coCartesian morphisms $X \rightarrow X_i$ covering the inert morphisms $\rho_i : (n) \rightarrow (1)$ for $1 \leq i \leq n$. We claim that these maps exhibit an object of $(\mathcal{C} \otimes \mathcal{D} \otimes)^{(n)}$-product of the objects $X_i$. Using our assumption that $\mathcal{C} \otimes$ and $\mathcal{D} \otimes$ are $\infty$-operads, we deduce that these maps exhibit $X$ as a $p$-product of the objects $\{X_i\}$. It therefore suffices to show that they exhibit $X$ as a product of the objects $p(X_i)$ in the $\infty$-category $N(\text{Sub})$, which follows immediately from the definitions.

It remains only to show that for each $n \geq 0$, the canonical functor $\phi : (\mathcal{C} \otimes \mathcal{D} \otimes)_{(n)} \rightarrow (\mathcal{C} \otimes \mathcal{D} \otimes)^{(n)}_{(n)}$ is essentially surjective. We can identify the latter with $(\mathcal{C} \otimes \mathcal{D} \otimes)^{(n)}_{(n)}$. Given a collection of objects $X_1, \ldots, X_n$ of $\mathcal{C} \otimes \mathcal{D}$, we let $S = \{\ast\} \cup \{i : X_i \in \mathcal{C}\}$ and $T = \{\ast\} \cup \{i : X_i \in \mathcal{D}\}$. Let $C = \bigoplus_{X_i \in \mathcal{C}} X_i \in \mathcal{C}^{\{s\}}$ and let $D = \bigoplus_{X_i \in \mathcal{D}} X_i \in \mathcal{D}^{\{t\}}$. Then $X = (\langle n \rangle, S, T, C, D)$ is an object of $(\mathcal{C} \otimes \mathcal{D} \otimes)_{(n)}$ such that $\phi(X) \simeq (X_1, \ldots, X_n)$. □
Proof of Theorem 2.2.3.6. Assertion (1) follows from the evident isomorphisms
\[(e^\circ \boxplus d^\circ)_- \simeq e^\circ \times d^\circ_{(0)} \quad (e^\circ \boxplus d^\circ)_+ \simeq e^\circ_{(0)} \times d^\circ,\]
together with the observation that \(e^\circ_{(0)}\) and \(d^\circ_{(0)}\) are contractible Kan complexes. Assertion (2) follows immediately from (1). To prove (3), let \(X\) determine a map \(\varphi\) immediately from (1). To prove (3), let \(X = (e^\circ \boxplus d^\circ)_- \cap (e^\circ \boxplus d^\circ)_+ \simeq e^\circ_{(0)} \times d^\circ_{(0)}\) and let \(\mathcal{Y} = (e^\circ \boxplus d^\circ)_- \cup (e^\circ \boxplus d^\circ)_+\). Let \(A\) denote the full subcategory of \(\text{Fun}_{N(\mathcal{J}_{\text{fin}})}(\mathcal{Y}, e^\circ)\) spanned by those functors whose restriction to both \((e^\circ \boxplus d^\circ)_-\) and \((e^\circ \boxplus d^\circ)_+\) are \(\infty\)-operad maps. We have homotopy pullback diagram

\[
\begin{array}{ccc}
A & \rightarrow & \text{Fun}^{lax}((e^\circ \boxplus d^\circ)_-, e^\circ) \\
\downarrow & & \downarrow \\
\text{Fun}^{lax}((e^\circ \boxplus d^\circ)_+, e^\circ) & \rightarrow & \text{Fun}_{N(\mathcal{J}_{\text{fin}}})(\mathcal{X}, e^\circ).
\end{array}
\]

Since \(e^\circ_{(0)}\) is a contractible Kan complex, the simplicial set \(\text{Fun}_{N(\mathcal{J}_{\text{fin}})}(\mathcal{X}, e^\circ)\) is also a contractible Kan complex, so the map
\[A \rightarrow \text{Fun}^{lax}((e^\circ \boxplus d^\circ)_-, e^\circ) \times \text{Fun}^{lax}((e^\circ \boxplus d^\circ)_+, e^\circ)\]
is a categorical equivalence. We will complete the proof by showing that the map \(\text{Fun}^{lax}((e^\circ \boxplus d^\circ), e^\circ) \rightarrow A\) is a trivial Kan fibration.

Let \(q : e^\circ \rightarrow N(\mathcal{J}_{\text{fin}})\) denote the projection map. In view of Proposition T.4.3.2.15, it will suffice to show the following:

(a) An arbitrary map \(A \in \text{Fun}_{N(\mathcal{J}_{\text{fin}})}(e^\circ \boxplus d^\circ, e^\circ)\) is an \(\infty\)-operad map if and only if it satisfies the following conditions:

(i) The restriction \(A_0 = A|\mathcal{Y}\) belongs to \(A\).

(ii) The map \(A\) is a \(q\)-right Kan extension of \(A_0\).

(b) For every object \(A_0 \in A\), there exists an extension \(A \in \text{Fun}_{N(\mathcal{J}_{\text{fin}})}(e^\circ \boxplus d^\circ, e^\circ)\) of \(A_0\) which satisfies the equivalent conditions of (a).

To prove (a), consider an object \(A \in \text{Fun}_{N(\mathcal{J}_{\text{fin}})}(e^\circ \boxplus d^\circ, e^\circ)\) and an object \(X = ([n], S, T, C, D) \in e^\circ \boxplus d^\circ\). Choose morphisms \(\alpha : C \rightarrow C_0\) and \(\beta : D \rightarrow D_0\), where \(C_0 \in e^\circ_{(0)}\) and \(D_0 \in d^\circ_{(0)}\). Set
\[X_- = ([S], [S], \{\ast\}, C, D_0) \quad X_0 = ([0], \{\ast\}, \{\ast\}, C_0, D_0) \quad X_+ = ([T], \{\ast\}, [T], C_0, D).
\]
Then \(\alpha\) and \(\beta\) determine a commutative diagram

\[
\begin{array}{ccc}
X & \rightarrow & X_-
\downarrow & & \downarrow \\
X_+ & \rightarrow & X_0.
\end{array}
\]

Using Theorem T.4.1.3.1, we deduce that this diagram determines a map
\[\phi : A^2_2 \rightarrow \mathcal{Y} \times e^\circ \boxplus d^\circ (e^\circ \boxplus d^\circ),\]
such that \(\phi\) is right cofinal. It follows that \(A\) is a \(q\)-right Kan extension of \(A_0\) at \(X\) if and only if the diagram

\[
\begin{array}{ccc}
A(X) & \rightarrow & A(X_-) \\
\downarrow & & \downarrow \\
A(X_+) & \rightarrow & A(X_0)
\end{array}
\]
is a \(q\)-pullback diagram. Since \(q : \mathcal{E}^\otimes \to N(\mathcal{F}\text{in}_n)\) is an \(\infty\)-operad, this is equivalent to the requirement that the maps \(A(X_-) \leftarrow A(X) \to A(X_+)\) are inert. In other words, we obtain the following version of (a):

\[(a')\] A map \(A \in \text{Fun}_N(\mathcal{F}\text{in}_n)(\mathcal{E}^\otimes \boxtimes \mathcal{D}^\otimes, \mathcal{E}^\otimes)\) is a \(q\)-right Kan extension of \(A_0 = A|_{\mathcal{F}}\) if and only if, for every object \(X \in \mathcal{E}^\otimes \boxtimes \mathcal{D}^\otimes\) as above, the maps \(A(X_-) \leftarrow A(X) \to A(X_+)\) are inert.

We now prove (a) Suppose first that \(A\) is an \(\infty\)-operad map; we wish to prove that \(A\) satisfies conditions (i) and (ii). Condition (i) follows immediately from the description of the inert morphisms in \(\mathcal{E}^\otimes \boxtimes \mathcal{D}^\otimes\) provided by the proof of Proposition 2.2.3.5, and condition (ii) follows from (a'). Conversely, suppose that (i) and (ii) are satisfied. We wish to prove that \(A\) preserves inert morphisms. In view of Remark 2.1.2.9, it will suffice to show that \(A(X) \to A(Y)\) is inert whenever \(X \to Y\) is an inert morphism such that \(Y \in (\mathcal{E}^\otimes \boxtimes \mathcal{D}^\otimes)_{(1)}\). It follows that \(Y \in \mathcal{Y}\); we may therefore assume without loss of generality that \(Y \in (\mathcal{E}^\otimes \boxtimes \mathcal{D}^\otimes)_-\). The map \(X \to Y\) then factors as a composition of inert morphisms \(X \to X_- \to Y\), where \(X_-\) is defined as above. Then \(A(X) \to A(X_-)\) is inert by virtue of (ii) and (a'), while \(A(X_-) \to A(Y)\) is inert by virtue of assumption (i).

To prove (b), it will suffice (by virtue of Lemma T.4.3.2.13) to show that for each \(X \in \mathcal{E}^\otimes \boxtimes \mathcal{D}^\otimes\), the induced diagram

\[
y_X/ \to y \xrightarrow{\phi} \mathcal{E}^\otimes
\]

admits a \(q\)-limit. Since \(\phi\) is right cofinal, it suffices to show that there exists a \(q\)-limit of the diagram

\[
A_0(X_-) \to A_0(X_0) \leftarrow A_0(X_+).
\]

The existence of this \(q\)-limit follows immediately from the assumption that \(\mathcal{E}^\otimes\) is an \(\infty\)-operad. \(\square\)

### 2.2.4 Monoidal Envelopes

Every symmetric monoidal \(\infty\)-category \(\mathcal{C}^\otimes \to N(\mathcal{F}\text{in}_n)\) can be regarded as an \(\infty\)-operad, and every symmetric monoidal functor determines a map between the underlying \(\infty\)-operads. This observation provides a forgetful functor from the \(\infty\)-category \(\mathcal{C}\text{at}_\infty^\otimes \simeq \mathcal{C}\text{Alg}(\mathcal{C}\text{at}_\infty)\) of symmetric monoidal \(\infty\)-categories to the \(\infty\)-category \(\mathcal{O}_{\mathcal{P}}\) of \(\mathcal{O}\)-operads. Our goal in this section is to construct a left adjoint to this forgetful functor. More generally, we will give a construction which converts an arbitrary fibration of \(\infty\)-operads \(\mathcal{C}^\otimes \to \mathcal{O}^\otimes\) into a coCartesian fibration of \(\infty\)-operads \(\text{Env}_{\mathcal{O}}(\mathcal{C}^\otimes) \to \mathcal{O}^\otimes\).

**Construction 2.2.4.1.** Let \(\mathcal{O}^\otimes\) be an \(\infty\)-operad. We let \(\text{Act}(\mathcal{O}^\otimes)\) denote the full subcategory of \(\text{Fun}(\Delta^1, \mathcal{O}^\otimes)\) spanned by the active morphisms. Suppose that \(p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes\) is a fibration of \(\infty\)-operads. We let \(\text{Env}_{\mathcal{O}}(\mathcal{C}^\otimes)\) denote the fiber product

\[
\mathcal{C}^\otimes \times_{\text{Fun}(\{0\}, \mathcal{O}^\otimes)} \text{Act}(\mathcal{O}^\otimes).
\]

We will refer to \(\text{Env}_{\mathcal{O}}(\mathcal{C}^\otimes)\) as the \(\mathcal{O}\)-monoidal envelope of \(\mathcal{C}^\otimes\). In the special case where \(\mathcal{O}^\otimes\) is the commutative \(\infty\)-operad, we will denote \(\text{Env}_{\mathcal{O}}(\mathcal{C}^\otimes)\) simply by \(\text{Env}(\mathcal{C}^\otimes)\).

**Remark 2.2.4.2.** More informally, we can identify \(\text{Env}_{\mathcal{O}}(\mathcal{C}^\otimes)\) with the \(\infty\)-category of pairs \((C, \alpha)\), where \(C \in \mathcal{C}^\otimes\) and \(\alpha : p(C) \to X\) is an active morphism in \(\mathcal{O}^\otimes\).

**Remark 2.2.4.3.** Let \(\mathcal{O}^\otimes\) be an \(\infty\)-operad. Evaluation at \(\{1\} \subseteq \Delta^1\) induces a map \(\text{Env}(\mathcal{C}^\otimes) \to N(\mathcal{F}\text{in}_n)\). We let \(\text{Env}(\mathcal{C}^\otimes)\) denote the fiber \(\text{Env}(\mathcal{C}^\otimes)_{\{1\}}\). Unwinding the definitions, we deduce that \(\text{Env}(\mathcal{C}^\otimes)\) can be identified with the subcategory \(\mathcal{C}^\otimes_{\mathcal{C}\text{act}} \subseteq \mathcal{C}^\otimes\) spanned by all objects and active morphisms between them.

We will defer the proof of the following basic result until the end of this section:

**Proposition 2.2.4.4.** Let \(p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes\) be a fibration of \(\infty\)-operads. Then evaluation at the vertex \(\{1\} \subseteq \Delta^1\) induces a coCartesian fibration of \(\infty\)-operads \(q : \text{Env}_{\mathcal{O}}(\mathcal{C}^\otimes) \to \mathcal{O}^\otimes\).
2.2. CONSTRUCTIONS OF $\infty$-OPERADS

Taking $\mathcal{O}^\otimes$ to be the commutative $\infty$-operad, we deduce the following:

**Corollary 2.2.4.5.** Let $\mathcal{E}^\otimes$ be an $\infty$-operad. Then there is a canonical symmetric monoidal structure on the $\infty$-category $\mathcal{O}_{\text{act}}^\otimes$ of active morphisms.

**Remark 2.2.4.6.** If $\mathcal{E}^\otimes$ is an $\infty$-operad, we let $\oplus : \mathcal{E}_{\text{act}}^\otimes \times \mathcal{E}_{\text{act}}^\otimes \to \mathcal{E}_{\text{act}}^\otimes$ denote the functor induced by the symmetric monoidal structure described in Corollary 2.2.4.5. This operation can be described informally as follows: if $X \in \mathcal{E}_{(m)}^\otimes$ classifies a sequence of objects $\{X_i \in \mathcal{E}\}_{1 \leq i \leq m}$ and $Y \in \mathcal{E}_{(n)}^\otimes$ classifies a sequence $\{Y_j \in \mathcal{E}\}_{1 \leq j \leq n}$, then $X \oplus Y \in \mathcal{E}_{(m+n)}^\otimes$ corresponds to the sequence of objects $\{X_i \in \mathcal{E}\}_{1 \leq i \leq m} \cup \{Y_j \in \mathcal{E}\}_{1 \leq j \leq n}$ obtained by concatenation.

**Remark 2.2.4.7.** The symmetric monoidal structure on $\mathcal{E}^\otimes$, described in Corollary 2.2.4.5 can actually be extended to a symmetric monoidal structure on $\mathcal{E}^\otimes$ itself, but we will not need this.

**Remark 2.2.4.8.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad, and let $q : \mathcal{E}^\otimes \to \mathcal{O}^\otimes$ be a $\mathcal{O}$-monoidal $\infty$-category. Then the collection of active $q$-coCartesian morphisms in $\mathcal{E}^\otimes$ is stable under the operation $\oplus : \mathcal{E}_{\text{act}}^\otimes \times \mathcal{E}_{\text{act}}^\otimes \to \mathcal{E}_{\text{act}}^\otimes$. To see this, let $\alpha : C \to C'$ and $\beta : D \to D'$ be active $q$-coCartesian morphisms in $\mathcal{E}^\otimes$. Let $\gamma : C \oplus D \to E$ be a $q$-coCartesian morphism lifting $q(\alpha \oplus \beta)$. We have a commutative diagram in $\mathcal{O}^\otimes$

$$
\begin{array}{ccc}
p(C) & \longrightarrow & p(D) \\
\downarrow & & \downarrow \\
p(C') & \longrightarrow & p(D')
\end{array}
$$

We can lift this to a diagram of $q$-coCartesian morphisms

$$
\begin{array}{ccc}
C & \longrightarrow & D \\
\downarrow & & \downarrow \\
C' & \longrightarrow & D'.
\end{array}
$$

Let $\delta : E \to C' \oplus D'$ be the canonical map in $\mathcal{E}^\otimes_{p(C' \oplus D')}$, the above diagram shows that the image of $\delta$ is an equivalence in both $\mathcal{E}^\otimes_{p(C')}$ and $\mathcal{E}^\otimes_{p(D')}$. Since $\mathcal{E}^\otimes_{p(C' \oplus D')} \simeq \mathcal{E}^\otimes_{p(C')} \times \mathcal{E}^\otimes_{p(D')}$, it follows that $\delta$ is an equivalence, so that $\alpha \oplus \beta$ is $q$-coCartesian as desired.

For any $\infty$-operad $\mathcal{O}^\otimes$, the diagonal embedding $\mathcal{O}^\otimes \to \text{Fun}(\Delta^1, \mathcal{O}^\otimes)$ factors through $\text{Act}(\mathcal{O}^\otimes)$. Pullback along this embedding induces an inclusion $\mathcal{E}^\otimes \subseteq \text{Env}_\mathcal{O}(\mathcal{E})^\otimes$ for any fibration of $\infty$-operads $\mathcal{E}^\otimes \to \mathcal{O}^\otimes$. It follows from Proposition 2.2.4.4 and Lemma 2.2.4.16 (below) that this inclusion is a map of $\infty$-operads. The terminology “$\mathcal{O}$-monoidal envelope” is justified by the following result:

**Proposition 2.2.4.9.** Let $p : \mathcal{E}^\otimes \to \mathcal{O}^\otimes$ be a fibration of $\infty$-operads and $p' : \text{Env}_\mathcal{O}(\mathcal{E})^\otimes \to \mathcal{O}^\otimes$ the induced coCartesian fibration of $\infty$-operads, and let $q : \mathcal{D}^\otimes \to \mathcal{O}^\otimes$ be another coCartesian fibration of $\infty$-operads. The inclusion $i : \mathcal{E}^\otimes \subseteq \text{Env}_\mathcal{O}(\mathcal{E})^\otimes$ induces an equivalence of $\infty$-categories

$$
\text{Fun}_\mathcal{O}(\text{Env}_\mathcal{O}(\mathcal{E}), \mathcal{D}) \to \text{Alg}_\mathcal{E}(\mathcal{D}).
$$

Here $\text{Fun}_\mathcal{O}(\mathcal{U}_\mathcal{O}(\mathcal{E}), \mathcal{D})$ denotes the full subcategory of $\text{Fun}_\mathcal{O}(\text{Env}_\mathcal{O}(\mathcal{E})^\otimes, \mathcal{D}^\otimes)$ spanned by those functors which carry $p'$-coCartesian morphisms to $q$-coCartesian morphisms, and $\text{Alg}_\mathcal{E}(\mathcal{D})$ the full subcategory of $\text{Fun}_\mathcal{O}(\mathcal{E}^\otimes, \mathcal{D}^\otimes)$ spanned by the maps of $\infty$-operads.

**Remark 2.2.4.10.** Since every diagonal embedding $\mathcal{O}^\otimes \to \text{Act}(\mathcal{O}^\otimes)$ is fully faithful, we conclude that for every fibration of $\infty$-operads $\mathcal{E}^\otimes \to \mathcal{O}^\otimes$ the inclusion $\mathcal{E}^\otimes \to \text{Env}_\mathcal{O}(\mathcal{E})^\otimes$ is fully faithful. In particular, we deduce that for every $\infty$-operad $\mathcal{E}^\otimes$ there exists a fully faithful $\infty$-operad map $\mathcal{E}^\otimes \to \mathcal{D}^\otimes$, where $\mathcal{D}^\otimes$ is a symmetric monoidal $\infty$-category.
We now turn to the proofs of Propositions 2.2.4.4 and 2.2.4.9. We will need several preliminary results.

**Lemma 2.2.4.11.** Let \( p: \mathcal{E} \to \mathcal{D} \) be a coCartesian fibration of \( \infty \)-categories. Let \( \mathcal{E}' \) be a full subcategory of \( \mathcal{E} \) satisfying the following conditions:

(i) For each \( D \in \mathcal{D} \), the inclusion \( \mathcal{E}'_D \subseteq \mathcal{E}_D \) admits a left adjoint \( L_D \).

(ii) For every morphism \( f: D \to D' \) in \( \mathcal{D} \), the associated functor \( f_1: \mathcal{E}_D \to \mathcal{E}_{D'} \) carries \( L_D \)-equivalences to \( L_{D'} \)-equivalences.

Then:

1. The restriction \( p'|=p|\mathcal{E}' \) is a coCartesian fibration.

2. Let \( f: C \to C' \) be a morphism in \( \mathcal{E}' \) lying over \( g: D \to D' \) in \( \mathcal{D} \), and let \( g_1: \mathcal{E}_D \to \mathcal{E}_{D'} \) be the functor induced by the coCartesian fibration \( p \). Then \( f \) is \( p' \)-coCartesian if and only if the induced map \( \alpha: g_1C \to C' \) is an \( L_{D'} \)-equivalence.

**Proof.** We first prove the “iff” direction of (2). According to Proposition T.2.4.4.3, it will suffice to show that for every object \( C'' \in \mathcal{E}' \) lying over \( D'' \in \mathcal{D} \), the outer square in the homotopy coherent diagram

\[
\begin{array}{ccc}
\text{Map}_\mathcal{E}(C'', C'') & \xrightarrow{\alpha} & \text{Map}_\mathcal{E}(g_1C, C'') \\
\downarrow & & \downarrow \\
\text{Map}_\mathcal{D}(D', D'') & \longrightarrow & \text{Map}_\mathcal{D}(D', D'')
\end{array}
\]

is a homotopy pullback square. Since the right square is a homotopy pullback (Proposition T.2.4.4.3), it will suffice to show that \( \theta \) induces a homotopy equivalence after passing the homotopy fiber over any map \( h: D' \to D'' \). Using Proposition T.2.4.4.2, we see that this is equivalent to the assertion that the map \( h_!(\alpha) \) is an \( L_{D''} \)-equivalence. This follows from (ii), since \( \alpha \) is an \( L_{D''} \)-equivalence.

To prove (1), it will suffice to show that for every \( C \in \mathcal{E}' \) and every \( g: p(C) \to D' \) in \( \mathcal{D} \), there exists a morphism \( f: C \to C'' \) lying over \( g \) satisfying the criterion of (2). We can construct \( f \) as a composition \( C \xrightarrow{f'} C'' \xrightarrow{h'} C' \), where \( f' \) is a \( p \)-coCartesian lift of \( g \) in \( \mathcal{E} \), and \( f'' \) is a \( p' \)-coCartesian lift of \( h' \) in \( \mathcal{E}' \), and \( f'' \) is a morphism in \( \mathcal{E}_{D'} \). The map \( f'' \) admits a factorization as a composition \( C'' \xrightarrow{h} C' \xrightarrow{h'} C' \), where \( h \) exhibits \( C'' \) as a \( \mathcal{E}'_{D'} \)-localization of \( C'' \). The first part of the proof shows that the composition \( h \circ f' \) is a \( p' \)-coCartesian lift of \( g \). Since \( f \) is also a \( p' \)-coCartesian lift of \( g \), we deduce that \( h' \) is an equivalence. It follows that \( f'' = h' \circ h \) exhibits \( C' \) as a \( \mathcal{E}'_{D'} \)-localization of \( C'' \simeq g_1C \), so that \( f \) satisfies the criterion of (2). \( \square \)

**Remark 2.2.4.12.** Let \( \mathcal{E}' \subseteq \mathcal{E} \) and \( p: \mathcal{E} \to \mathcal{D} \) be as in Lemma 2.2.4.11. Hypotheses (i) and (ii) are equivalent to the following:

(i) The inclusion \( \mathcal{E}' \subseteq \mathcal{E} \) admits a left adjoint \( L \).

(ii) The functor \( p \) carries each \( L \)-equivalence in \( \mathcal{E} \) to an equivalence in \( \mathcal{D} \).

Suppose first that (i) and (ii) are satisfied. To prove (i') and (ii'), it will suffice (by virtue of Proposition T.5.2.7.8) to show that for each object \( C \in \mathcal{E}_D \), if \( f: C \to C' \) exhibits \( C' \) as a \( \mathcal{E}'_{D'} \)-localization of \( C \), then \( f \) exhibits \( C' \) as a \( \mathcal{E}'_D \)-localization of \( C \). In other words, we must show that for each \( C'' \in \mathcal{E}' \) lying over \( D'' \in \mathcal{D} \), composition with \( f \) induces a homotopy equivalence \( \text{Map}_\mathcal{E}(C', C'') \to \text{Map}_\mathcal{D}(C, C'') \). Using Proposition T.2.4.4.2, we can reduce to showing that for every morphism \( g: D \to D'' \) in \( \mathcal{D} \), the induced map...
2.2. CONSTRUCTIONS OF $\infty$-OPERADS

$\text{Map}_{\mathcal{E}_D'}(gC', C'') \to \text{Map}_{\mathcal{E}_D'}(gC, C'')$ is a homotopy equivalence. For this, it suffices to show that $g(1)$ is an $L_{D'}$-equivalence, which follows immediately from (ii).

Conversely, suppose that (i) and (ii) are satisfied. We first prove (i). Fix $D \in \mathcal{D}$. To prove that the inclusion $\mathcal{C}_D' \subseteq \mathcal{C}_D$ admits a left adjoint, it will suffice to show that for each object $C' \in \mathcal{C}_D$ there exists a $\mathcal{C}_D'$-localization of $C$. The inclusion $\mathcal{C}_D' \subseteq \mathcal{C}_D$ exhibits a homotopy equivalence $\text{Map}_{\mathcal{C}_D'}(C', C'') \to \text{Map}_{\mathcal{C}_D}(C, C'')$. Using Proposition T.2.4.4.3, we deduce that $\mathcal{C}_D'$-localization of $C$. We claim that $f$ exhibits $C'$ as a $\mathcal{C}_D'$-localization of $C$. To prove this, it suffices to show that for each $C'' \in \mathcal{C}_D'$, composition with $f'$ induces a homotopy equivalence $\text{Map}_{\mathcal{C}_D}(C', C'') \to \text{Map}_{\mathcal{C}_D}(C, C'')$. Using Proposition T.2.4.4.2, we can reduce to showing that $f'$ induces a homotopy equivalence $\text{Map}_{\mathcal{C}_D}(C', C'') \to \text{Map}_{\mathcal{C}_D}(C, C'')$, which follows from the assumption that $f$ exhibits $C'$ as a $\mathcal{C}_D'$-localization of $C$.

We now prove (ii). Let $f : C \to C'$ be an $L_D$-equivalence in $\mathcal{C}_D$, and let $g : D \to D''$ be a morphism in $\mathcal{D}$. We wish to show that $g(1)$ is an $L_{D''}$-equivalence in $\mathcal{C}_{D''}$. In other words, we wish to show that for each object $C'' \in \mathcal{C}_{D''}$, the map $\text{Map}_{\mathcal{C}_{D''}}(gC', C'') \to \text{Map}_{\mathcal{C}_{D''}}(gC, C'')$ is a homotopy equivalence. This follows from Proposition T.2.4.4.2 and the fact that $\text{Map}_{\mathcal{C}_D}(C', C'') \to \text{Map}_{\mathcal{C}_D}(C, C'')$ is a homotopy equivalence.

**Lemma 2.2.4.13.** Let $p : \mathcal{E} \to \mathcal{D}$ be an inner fibration of $\infty$-categories. Let $\mathcal{D}' \subseteq \mathcal{D}$ be a full subcategory and set $\mathcal{C}' = \mathcal{D}' \times_{\mathcal{D}} \mathcal{E}$. Assume that:

(i) The inclusion $\mathcal{D}' \subseteq \mathcal{D}$ admits a left adjoint.

(ii) Let $C \in \mathcal{E}$ be an object and let $g : p(C) \to D$ be a morphism which exhibits $D$ as a $\mathcal{D}'$-localization of $p(C)$. Then $g$ can be lifted to a $p$-coCartesian morphism $C \to C'$.

Then:

1. A morphism $f : C \to C'$ exhibits $C'$ as a $\mathcal{C}'$-localization of $C$ if and only if $p(f)$ exhibits $p(C')$ as a $\mathcal{D}'$-localization of $p(C)$ and $f$ is $p$-coCartesian.

2. The inclusion $\mathcal{C}' \subseteq \mathcal{C}$ admits a left adjoint.

**Proof.** We first prove the “if” direction of (1). Fix an object $C'' \in \mathcal{C}'$; we wish to prove that $f$ induces a homotopy equivalence $\text{Map}_{\mathcal{C}}(C', C'') \to \text{Map}_{\mathcal{C}}(C, C'')$. Using Proposition T.2.4.4.3, we deduce that the homotopy coherent diagram

$$
\begin{array}{ccc}
\text{Map}_{\mathcal{C}}(C', C'') & \xrightarrow{} & \text{Map}_{\mathcal{C}}(C, C'') \\
\downarrow & & \downarrow \\
\text{Map}_{\mathcal{D}}(p(C'), p(C'')) & \xrightarrow{} & \text{Map}_{\mathcal{D}}(p(C), p(C''))
\end{array}
$$

is a homotopy pullback square. It therefore suffices to show that the bottom horizontal map is a homotopy equivalence, which follows from the assumptions that $p(C'') \in \mathcal{D}'$ and $p(f)$ exhibits $p(C')$ as a $\mathcal{D}'$-localization of $p(C)$.

Assertion (2) now follows from (ii) together with Proposition T.5.2.7.8. To complete the proof, we verify the “only if” direction of (1). Let $f : C \to C'$ be a morphism which exhibits $C'$ as a $\mathcal{C}'$-localization of $C$, and let $g : D \to D'$ be the image of $f$ in $\mathcal{D}$. Then $f$ factors as a composition

$$
C \xrightarrow{f'} gC \xrightarrow{f''} C';
$$
we wish to prove that $f''$ is an equivalence. This follows from the first part of the proof, which shows that $f'$ exhibits $gC$ as a $\mathcal{C}'$-localization of $C$.

**Lemma 2.2.4.14.** Let $p : \mathcal{E}^\circ \to \mathcal{O}^\circ$ be a fibration of $\infty$-operads, and let $\mathcal{D} = \mathcal{E}^\circ \times_{\text{Fun}(\{0\}, \mathcal{O}^\circ)} \text{Fun}(\Delta^1, \mathcal{O}^\circ)$. Then the inclusion $\text{Env}_{\mathcal{O}}(\mathcal{C})^\circ \subseteq \mathcal{D}$ admits a left adjoint. Moreover, a morphism $\alpha : D \to D'$ in $\mathcal{D}$ exhibits $D'$ as an $\text{Env}_{\mathcal{O}}(\mathcal{C})^\circ$-localization of $D$ if and only if $D'$ is active, the image of $\alpha$ in $\mathcal{O}^\circ$ is inert, and the image of $\alpha$ in $\mathcal{O}^\circ$ is an equivalence.
Proof. According to Proposition 2.1.2.4, the active and inert morphisms determine a factorization system on $O^\otimes$. It follows from Lemma T.5.2.8.19 that the inclusion $\text{Act}(O^\otimes) \subseteq \text{Fun}(\Delta^1, O^\otimes)$ admits a left adjoint, and that a morphism $\alpha : g \to g'$ in $\text{Fun}(\Delta^1, O^\otimes)$ corresponding to a commutative diagram

$$
\begin{array}{ccc}
X & \xrightarrow{f} & X' \\
\downarrow{g} & & \downarrow{g'} \\
Y & \xrightarrow{f'} & Y'
\end{array}
$$

in $O^\otimes$ exhibits $g'$ as an $\text{Act}(O^\otimes)$-localization of $g$ if and only if $g'$ is active, $f$ is inert, and $f'$ is an equivalence. The desired result now follows from Lemma 2.2.4.13.

Lemma 2.2.4.15. Let $p : C^\otimes \to O^\otimes$ be a fibration of $\infty$-operads, and let $D = C^\otimes \times_{\text{Fun}(\{0\}, O^\otimes)} \text{Fun}(\Delta^1, O^\otimes)$. Then:

1. Evaluation at $\{1\}$ induces a coCartesian fibration $q' : D \to O^\otimes$.
2. A morphism in $D$ is $q'$-coCartesian if and only if its image in $C^\otimes$ is an equivalence.
3. The map $q'$ restricts to a coCartesian fibration $q : \text{Env}_O(C^\otimes) \to O^\otimes$.
4. A morphism $f$ in $\text{Env}_O(C^\otimes)$ is $q$-coCartesian if and only if its image in $C^\otimes$ is inert.

Proof. Assertions (1) and (2) follow from Corollary T.2.4.7.12. Assertions (3) and (4) follow by combining Lemma 2.2.4.14, Remark 2.2.4.12, and Lemma 2.2.4.11.

Lemma 2.2.4.16. Let $C$ denote the full subcategory of $\text{Fun}(\Delta^1, N(\text{Fin}_*))$ spanned by the active morphisms, and let $p : C \to N(\text{Fin}_*)$ be given by evaluation on the vertex 1. Let $X \in C$ be an object with $p(X) = \langle n \rangle$. Choose an active morphism $\beta : \langle m \rangle \to \langle n \rangle$ in $C^\otimes$, and choose $p$-coCartesian morphisms $f_i : X \to X_i$ covering the maps $\rho^i : \langle n \rangle \to \langle 1 \rangle$ for $1 \leq i \leq n$. These morphisms determine a $p$-limit diagram $\langle n \rangle^\otimes \to C$.

Proof. Let $X$ be given by an active morphism $\beta : \langle m \rangle \to \langle n \rangle$. Each of the maps $f_i$ can be identified with a commutative diagram

$$
\begin{array}{ccc}
\langle m \rangle & \xrightarrow{\gamma_i} & \langle m_i \rangle \\
\downarrow{\beta} & & \downarrow{\beta_i} \\
\langle n \rangle & \xrightarrow{\rho^i} & \langle 1 \rangle
\end{array}
$$

where $\beta_i$ is active and $\gamma_i$ is inert. Unwinding the definitions, we must show the following:

(*) Given an active morphism $\beta' : \langle m' \rangle \to \langle n' \rangle$ in $\text{Fin}_*$, a map $\delta : \langle n' \rangle \to \langle n \rangle$, and a collection of commutative diagrams

$$
\begin{array}{ccc}
\langle m' \rangle & \xrightarrow{\epsilon} & \langle m_i \rangle \\
\downarrow{\rho'^i \circ \delta} & & \downarrow{\beta_i} \\
\langle n' \rangle & \xrightarrow{\rho^i \circ \delta} & \langle 1 \rangle
\end{array}
$$

there is a unique morphism $\epsilon : \langle m' \rangle \to \langle m \rangle$ such that $\epsilon_i = \gamma_i \circ \epsilon$.

For each $j \in \langle m' \rangle$, let $j' = (\delta \circ \beta')(j) \in \langle n \rangle$. Then $\epsilon$ is given by the formula

$$
\epsilon(j) = \begin{cases} 
* & \text{if } j' = * \\
\gamma_j^{-1}(\epsilon_i(j)) & \text{if } j' \neq *.
\end{cases}
$$

\qed
2.2. CONSTRUCTIONS OF ∞-OPERADS

Proof of Proposition 2.2.4.4. Lemma 2.2.4.15 implies that \( q \) is a coCartesian fibration. It will therefore suffice to show that Env\(_{(C)}\) is an ∞-operad. Let \( r \) denote the composition

\[
\text{Env}_C(C) \xrightarrow{\mathcal{O}} C \xrightarrow{\mathcal{O}} \text{Fin}_r.
\]

Let \( X \in \text{Env}_C(C) \), and choose \( r \)-coCartesian morphisms \( X \to X_i \) covering \( \rho^i : (n) \to (1) \) for \( 1 \leq i \leq n \). We wish to prove that these morphisms determine an \( r \)-limit diagram \( \alpha : (n)^{\circ \circ} \to \text{Env}_C(C) \).

Let \( \mathcal{D} = C \times_{\text{Fun}(\{0\}, C)} \text{Fun}(\Delta^1, C) \). Then \( r \) extends to a map \( r' : \mathcal{D} \to \text{Fin}_r \). To show that \( \alpha \) is an \( r \)-limit diagram, it will suffice to show that \( \alpha \) is an \( r' \)-limit diagram. Write \( r' \) as a composition

\[
\begin{array}{c}
\mathcal{D} \xrightarrow{r_0} \text{Fun}(\Delta^1, C) \xrightarrow{r_1} \text{Fin}(\Delta^1, \text{Fin}_r) \xrightarrow{r_2} \text{Fin}_r.
\end{array}
\]

In view of Proposition T.4.3.1.5, it will suffice to show that \( \alpha \) is an \( r_0' \)-limit diagram, that \( r_0' \circ \alpha \) is an \( r_1' \)-limit diagram, and that \( r_1' \circ r_0' \circ \alpha \) is an \( r_2' \)-limit diagram. The second of these assertions follows from Remark 2.1.2.6 and Lemma 3.2.2.9, and the last from Lemma 2.2.4.16. To prove that \( \alpha \) is an \( r_0' \)-limit diagram, we consider the pullback diagram

\[
\begin{array}{ccc}
\mathcal{D} & \to & \text{Fun}(\Delta^1, C) \\
\downarrow & & \downarrow \\
\mathcal{E} & \to & C.
\end{array}
\]

Using Proposition T.4.3.1.5, we are reduced to the problem of showing that the induced map \( (n)^{\circ \circ} \to C \) is a \( p \)-limit diagram; this follows from Remark 2.1.2.11.

To complete the proof, it will suffice to show for any finite collection of objects \( X_i \in \text{Env}_C(C) \) \((\text{parametrized by } 1 \leq i \leq n)\), there exists an object \( X \in \text{Env}_C(C) \) and a collection of \( r \)-coCartesian morphisms \( X \to X_i \) covering the maps \( \rho^i : (n) \to (1) \). Each \( X_i \) can be identified with an object \( C_i \in C \) and an active morphism \( \beta_i : p(C_i) \to Y_i \in C \), where \( Y_i \in C \). The objects \( Y_i \) determine a diagram \( g : (n)^{\circ \circ} \to C \).

Using the assumption that \( C \) is an ∞-operad, we deduce the existence of an object \( Y \in C \) and a collection of inert morphisms \( Y \to Y_i \) covering the maps \( \rho^i : (n) \to (1) \). We regard these morphisms as providing an object \( \mathbf{Y} \in C \) lifting \( Y \). To construct the object \( \mathbf{Y} \) and the maps \( X \to X_i \), it suffices to select a morphism \( Z \to \mathbf{Y} \) in \( C \). The existence of such a morphism follows from the observation that \( \mathbf{Y} \) is a final object of \( C \).

Proof of Proposition 2.2.4.9. Let \( E \) denote the essential image of \( i : C \to \text{Env}_C(C) \). We can identify \( E \) with the full subcategory of \( \text{Env}_C(C) \) spanned by those objects \( (X, \alpha : p(X) \to Y) \) for which \( X \in E \) and \( \alpha \) is an equivalence in \( C \). We observe that \( i \) induces an equivalence of ∞-operads \( C \to E \). It will therefore suffice to prove that the restriction functor

\[
\text{Fun}_E(C, \mathcal{D}) \to \text{Alg}_E(C(\mathcal{D}))
\]

is an equivalence of ∞-categories. In view of Proposition T.4.3.2.15, it will suffice to show the following:

(a) Every ∞-operad map \( \theta_0 : E \to D \) admits a q-left Kan extension \( \theta : \text{Env}_C(C) \to D \).

(b) An arbitrary map \( \theta : \text{Env}_C(C) \to D \) in \( (\text{Set}_\Delta)_{/\mathcal{O}} \) is a \( \mathcal{O} \)-monoidal functor if and only if it is a q-left Kan extension of \( \theta_0 = \theta | E \) and \( \theta_0 \) is an ∞-operad map.

To prove (a), we will use criterion of Lemma T.4.3.2.13: it suffices to show that for every object \( \mathbf{X} = (X, \alpha : p(X) \to Y) \) in \( \text{Env}_C(C) \), the induced diagram \( E \times_{\text{Env}_C(C)} \mathbf{X} \to D \) admits a q-colimit.
covering the natural map \( (\mathcal{E} \otimes \times_{\text{Env}_\mathcal{O}(\mathcal{C})} \text{End}_\mathcal{O}(\mathcal{E}) \otimes/X) \rightarrow \mathcal{D} \). To see this, we observe that the \( \infty \)-category \( \mathcal{E} \otimes \times_{\text{Env}_\mathcal{O}(\mathcal{C})} \text{Env}_\mathcal{O}(\mathcal{E}) \otimes/X \) has a final object, given by the pair \((X, \mathrm{id}_{p(X)})\). It therefore suffices to show that there exists a \( q \)-coCartesian morphism \( \theta_0(X, \mathrm{id}_{p(X)}) \rightarrow C \) lifting \( \alpha : p(X) \rightarrow Y \), which follows from the assumption that \( q \) is a coCartesian fibration. This completes the proof of (a) and yields the following version of (b):

(b) Let \( \theta : \text{Env}_\mathcal{O}(\mathcal{C}) \rightarrow \mathcal{D} \) be a morphism in \((\text{Set}_\Delta)_{/\mathcal{O}}\) such that the restriction \( \theta_0 = \theta|_{\mathcal{E}} \) is an \( \infty \)-operad map. Then \( \theta \) is a \( q \)-left Kan extension of \( \theta_0 \) if and only if, for every object \((X, \alpha : p(X) \rightarrow Y) \in \text{Env}(\mathcal{O})\), the canonical map \( \theta(X, \mathrm{id}_{p(X)}) \rightarrow \theta(X, \alpha) \) is \( q \)-coCartesian.

We now prove (b). Let \( \theta : \text{Env}_\mathcal{O}(\mathcal{C}) \rightarrow \mathcal{D} \) be such that the restriction \( \theta_0 = \theta|_{\mathcal{E}} \) is an \( \infty \)-operad map. In view of \((b')\), it will suffice to show that \( \theta \) is a \( \mathcal{O} \)-monoidal functor if and only if \( \theta(X, \mathrm{id}_{p(X)}) \rightarrow \theta(X, \alpha) \) is \( q \)-coCartesian, for each \((X, \alpha) \in \text{Env}_\mathcal{O}(\mathcal{C})\). The “only if” direction is clear, since Lemma 2.2.4.16 implies that the morphism \((X, \mathrm{id}_{p(X)}) \rightarrow (X, \alpha) \in \text{Env}_\mathcal{O}(\mathcal{C})\) is \( p' \)-coCartesian, where \( p' : \text{Env}_\mathcal{O}(\mathcal{C}) \rightarrow \mathcal{O} \) denotes the projection. For the converse, suppose that we are given a \( p' \)-coCartesian morphism \( f : (X, \alpha) \rightarrow (Y, \alpha') \) in \( \text{Env}_\mathcal{O}(\mathcal{C})\). Let \( \beta : p(X) \rightarrow p(Y) \) be the induced map in \( \mathcal{O}\), and choose a factorization \( \beta \sim \beta'' \circ \beta' \) where \( \beta' \) is inert and \( \beta'' \) is active. Choose a \( p \)-coCartesian morphism \( \overline{\beta} : X \rightarrow X'' \) lifting \( \beta' \). We then have a commutative diagram

\[
\begin{array}{ccc}
(X, \mathrm{id}_{p(X)}) & \xrightarrow{f'} & (X'', \mathrm{id}_{p(X''')}) \\
| & & | \\
(Y, \alpha) & \xrightarrow{f} & (Y', \alpha').
\end{array}
\]

The description of \( p' \)-coCartesian morphisms supplied by Lemma 2.2.4.16 shows that the map \( X'' \rightarrow X' \) is an equivalence in \( \mathcal{O}\). If \( \theta \) satisfies the hypotheses of \((b')\), then \( \theta(g) \) and \( \theta(g') \) are \( q \)-coCartesian. The assumption that \( \theta_0 \) is an \( \infty \)-operad map guarantees that \( \theta(f') \) is \( q \)-coCartesian. It follows from Proposition T.2.4.1.7 that \( \theta(f) \) is \( q \)-coCartesian. By allowing \( f \) to range over all morphisms in \( \text{Env}_\mathcal{O}(\mathcal{C}) \) we deduce that \( \theta \) is a \( \mathcal{O} \)-monoidal functor, as desired.

\[\square\]

### 2.2.5 Tensor Products of \( \infty \)-Operads

Let \( \mathcal{O} \) and \( \mathcal{O}' \) be a pair of \( \infty \)-operads. Our goal in this section is to introduce a new \( \infty \)-operad \( \mathcal{O} \otimes \mathcal{O}' \), which we call the tensor product of \( \mathcal{O} \) and \( \mathcal{O}' \). This tensor product is characterized (up to equivalence) by the existence of a map \( \mathcal{O} \otimes \mathcal{O}' \rightarrow \mathcal{O} \otimes \mathcal{O}' \) with a certain universal property: see Definition 2.2.5.3. This universal property guarantees the existence of an equivalence of \( \infty \)-categories \( \text{Alg}_{\mathcal{O}'(\mathcal{C})} \rightarrow \text{Alg}_{\mathcal{O}}(\text{Alg}_{\mathcal{O}'(\mathcal{C})}) \), for every symmetric monoidal \( \infty \)-category \( \mathcal{C} \): here \( \text{Alg}_{\mathcal{O}'(\mathcal{C})} \) is endowed with a symmetric monoidal structure determined by the tensor product in \( \mathcal{C} \).

**Notation 2.2.5.1.** We define a functor \( \wedge : \mathcal{F} \otimes \mathcal{F} \rightarrow \mathcal{F} \otimes \mathcal{F} \) as follows:

(i) On objects, \( \wedge \) is given by the formula \( \langle m \rangle \wedge \langle n \rangle = \langle mn \rangle \).

(ii) If \( f : \langle m \rangle \rightarrow \langle m' \rangle \) and \( g : \langle n \rangle \rightarrow \langle n' \rangle \) are morphisms in \( \mathcal{F} \otimes \mathcal{F} \), then \( f \wedge g \) is given by the formula

\[
(f \wedge g)(an + b - n) = \begin{cases} \ast & \text{if } f(a) = \ast \text{ or } g(b) = \ast \\ f(a)n' + g(b) - n' & \text{otherwise.} \end{cases}
\]

In other words, \( \wedge \) is given by the formula \( \langle m \rangle \wedge \langle n \rangle = ((m) \otimes (n))_{\ast} \), where we identify \( (m)^{\otimes} \times (n)^{\otimes} \) with \( (mn)^{\otimes} \) via the lexicographical ordering.

**Remark 2.2.5.2.** The operation \( \wedge \) of Notation 2.2.5.1 is associative, and endows \( \mathcal{F} \otimes \mathcal{F} \) with the structure of a strict monoidal category (that is, we have equalities \( (l \wedge \langle m \rangle) \wedge \langle n \rangle = (l \wedge \langle m \rangle) \wedge \langle n \rangle \), rather than just isomorphisms). In particular, the nerve \( N(\mathcal{F} \otimes \mathcal{F}) \) has the structure of a simplicial monoid.
2.2. CONSTRUCTIONS OF $\infty$-OPERADS

**Definition 2.2.5.3.** Let $\mathcal{O}^\otimes$, $\mathcal{O}'^\otimes$, and $\mathcal{O}''^\otimes$ be $\infty$-operads. A **bifunctor of $\infty$-operads** is a map $f : \mathcal{O}^\otimes \times \mathcal{O}'^\otimes \to \mathcal{O}''^\otimes$ with the following properties:

(i) The diagram

\[
\begin{array}{ccc}
\mathcal{O}^\otimes \times \mathcal{O}'^\otimes & \rightarrow & \mathcal{O}''^\otimes \\
\downarrow & & \downarrow \\
N(\text{Fin}_*) \times N(\text{Fin}_*) & \rightarrow & N(\text{Fin}_*)
\end{array}
\]

commutes.

(ii) For every inert morphism $\alpha$ in $\mathcal{O}^\otimes$ and every inert morphism $\beta$ in $\mathcal{O}'^\otimes$, the image $f(\alpha, \beta)$ is an inert morphism in $\mathcal{O}''^\otimes$.

We let $\text{BiFunc}(\mathcal{O}^\otimes, \mathcal{O}'^\otimes; \mathcal{O}''^\otimes)$ denote the full subcategory of $\text{Fun}(\mathcal{O}^\otimes \times \mathcal{O}'^\otimes \to \mathcal{O}''^\otimes)$ spanned by those maps which satisfy (ii); we will refer to $\text{BiFunc}(\mathcal{O}^\otimes, \mathcal{O}'^\otimes; \mathcal{O}''^\otimes)$ as the **$\infty$-category of $\infty$-operad bifunctors from $\mathcal{O}^\otimes \times \mathcal{O}'^\otimes$ into $\mathcal{O}''^\otimes$**.

Given an $\infty$-operad bifunctor $f : \mathcal{O}^\otimes \times \mathcal{O}'^\otimes \to \mathcal{O}''^\otimes$ and another $\infty$-operad $\mathcal{C}^\otimes$, composition with $f$ determines a functor $\theta : \text{Alg}_{\mathcal{O}''^\otimes}(\mathcal{C}) \to \text{BiFunc}(\mathcal{O}^\otimes, \mathcal{O}'^\otimes; \mathcal{C}^\otimes)$. We will say that $f$ **exhibits $\mathcal{O}''^\otimes$ as a tensor product of $\mathcal{O}^\otimes$ and $\mathcal{O}'^\otimes** if the functor $\theta$ is an equivalence for every $\infty$-operad $\mathcal{C}^\otimes$.

**Remark 2.2.5.4.** For every triple of $\infty$-operads $\mathcal{O}^\otimes$, $\mathcal{O}'^\otimes$, and $\mathcal{O}''^\otimes$, we let $\text{Mul}_{\text{Op}_\infty}^\infty(\{\mathcal{O}^\otimes, \mathcal{O}'^\otimes\}, \mathcal{O}''^\otimes)$ denote the largest Kan complex contained in the $\infty$-category $\text{BiFunc}(\mathcal{O}^\otimes, \mathcal{O}'^\otimes; \mathcal{O}''^\otimes)$. We claim that a bifunctor of $\infty$-operads $f : \mathcal{O}^\otimes \times \mathcal{O}'^\otimes \to \mathcal{O}''^\otimes$ exhibits $\mathcal{O}''^\otimes$ as a tensor product of $\mathcal{O}^\otimes$ with $\mathcal{O}'^\otimes$ if and only if, for every $\infty$-operad $\mathcal{C}^\otimes$, composition with $f$ induces a homotopy equivalence $\theta_{\mathcal{C}^\otimes} : \text{Alg}_{\mathcal{O}''^\otimes}(\mathcal{C})^\otimes \to \text{Mul}_{\text{Op}_\infty}^\infty(\{\mathcal{O}^\otimes, \mathcal{O}'^\otimes\}, \mathcal{O}''^\otimes)$. The “only if” direction is clear. For the converse, we observe that to show that the functor $\text{Alg}_{\mathcal{O}''^\otimes}(\mathcal{C}) \to \text{BiFunc}(\mathcal{O}^\otimes, \mathcal{O}'^\otimes; \mathcal{C}^\otimes)$ is an equivalence of $\infty$-categories, it suffices to show that for every simplicial set $K$ the induced functor $\text{Fun}(K, \text{Alg}_{\mathcal{O}''^\otimes}(\mathcal{C})) \to \text{Fun}(K, \text{BiFunc}(\mathcal{O}^\otimes, \mathcal{O}'^\otimes; \mathcal{C}^\otimes))$ induces a homotopy equivalence from $\text{Fun}(K, \text{Alg}_{\mathcal{O}''^\otimes}(\mathcal{C}))^\otimes$ to $\text{Fun}(K, \text{BiFunc}(\mathcal{O}^\otimes, \mathcal{O}'^\otimes; \mathcal{C}^\otimes))^\otimes$. Unwinding the definitions, we see that this map is given by $\theta_{\mathcal{D}^\otimes}$, where $\mathcal{D}^\otimes$ denotes the $\infty$-operad $\text{Fun}(K, \mathcal{C}^\otimes) \times_{\text{Fun}(K, N(\text{Fin}_*)))} N(\text{Fin}_*)$.

It is immediate from the definition that if a pair of $\infty$-operads $\mathcal{O}^\otimes$ and $\mathcal{O}'^\otimes$ admits a tensor product $\mathcal{O}''^\otimes$, then $\mathcal{O}''^\otimes$ is determined uniquely up to equivalence. To prove the existence of the tensor product it is convenient to work in the more general setting of $\infty$-preoperads:

**Notation 2.2.5.5.** Let $\mathcal{X} = (X, M)$ and $\mathcal{Y} = (Y, M')$ be $\infty$-preoperads: that is, $X$ and $Y$ are simplicial sets equipped with maps $X \to N(\text{Fin}_*) \leftarrow Y$, and $M$ and $M'$ are collections of edges of $X$ and $Y$. We let $\mathcal{X} \otimes \mathcal{Y}$ denote the $\infty$-preoperad $(X \times Y, M \times M')$, where we regard $X \times Y$ as an object of $(\text{Set}_\Delta)_{/N(\text{Fin}_*)}$ via the map $X \times Y \to N(\text{Fin}_*) \times N(\text{Fin}_*) \overset{\sim}{\to} N(\text{Fin}_*)$.

Unwinding the definitions (and using Remark 2.2.5.4), we see that a bifunctor of $\infty$-operads

\[
f : \mathcal{O}^\otimes \times \mathcal{O}'^\otimes \to \mathcal{O}''^\otimes
\]

exhibits $\mathcal{O}''^\otimes$ as a tensor product of $\mathcal{O}^\otimes$ and $\mathcal{O}'^\otimes$ if and only if the induced map $\mathcal{O}^\otimes \times \mathcal{O}'^\otimes \to \mathcal{O}''^\otimes$ is a weak equivalence of $\infty$-preoperads. In other words, a tensor product of a pair of $\infty$-operads $\mathcal{O}^\otimes$ and $\mathcal{O}'^\otimes$ can be identified with a fibrant replacement for the object $\mathcal{O}^\otimes \times \mathcal{O}'^\otimes$ in the category $\text{Op}_\infty$. This proves:

**Proposition 2.2.5.6.** Let $\mathcal{O}^\otimes$ and $\mathcal{O}'^\otimes$ be $\infty$-operads. Then there exists a bifunctor of $\infty$-operads $\mathcal{O}^\otimes \times \mathcal{O}'^\otimes \to \mathcal{O}''^\otimes$ which exhibits $\mathcal{O}''^\otimes$ as a tensor product of $\mathcal{O}^\otimes$ and $\mathcal{O}'^\otimes$. 

We now show that the operation $\odot$ is compatible with the $\infty$-operadic model structure on $\mathcal{P}Op_\infty$.

**Proposition 2.2.5.7.** The functor $\odot$ endows $\mathcal{P}Op_\infty$ with the structure of a monoidal model category.

**Remark 2.2.5.8.** In the approach to $\infty$-operads based on dendroidal sets, one can do better: the tensor product of $\infty$-operads is modelled by an operation which is commutative up to isomorphism. We refer to [31] for a discussion.

**Proof of Proposition 2.2.5.7.** Since every object of $\mathcal{P}Op_\infty$ is cofibrant, it will suffice to show that the functor
\[
\odot : \mathcal{P}Op_\infty \times \mathcal{P}Op_\infty \to \mathcal{P}Op_\infty
\]
is a left Quillen bifunctor. Let $\mathcal{P}$ be as in the proof of Proposition 2.1.4.6. Using Remark B.2.5, we deduce that the Cartesian product functor $\mathcal{P}Op_\infty \times \mathcal{P}Op_\infty \to (\mathcal{Set})_\mathcal{P}/\mathcal{P}$ is a left Quillen bifunctor. The desired result now follows by applying Proposition B.2.9 to the product functor $N(\mathcal{Fin}_*) \times N(\mathcal{Fin}_*) \to N(\mathcal{Fin}_*)$.

Our next goal is to discuss the symmetry properties of the tensor product construction on $\infty$-operads. Here we encounter a subtlety: the functor $\otimes$ is a left Quillen bifunctor. Let $\mathcal{P}$ be as in the proof of Proposition 2.1.4.6. Using Remark B.2.5, we deduce that the Cartesian product functor $\mathcal{P}Op_\infty \times \mathcal{P}Op_\infty \to (\mathcal{Set})_\mathcal{P}/\mathcal{P}$ is a left Quillen bifunctor. The desired result now follows by applying Proposition B.2.9 to the product functor $N(\mathcal{Fin}_*) \times N(\mathcal{Fin}_*) \to N(\mathcal{Fin}_*)$.

**Notation 2.2.5.9.** Let $F : \mathcal{Fin}_* \times \cdots \times \mathcal{Fin}_* \to \mathcal{Fin}_*$ be a functor. We will say that $F$ is a smash product functor if it has the following properties:

1. There exists an isomorphism (automatically unique) $F((1), \ldots, (1)) \simeq (1)$.
2. The functor $F$ preserves coproducts separately in each variable.

**Example 2.2.5.10.** The functor $F : \mathcal{Fin}_* \times \cdots \times \mathcal{Fin}_* \to \mathcal{Fin}_*$ given by $F((n_1), \ldots, (n_k)) = \langle n_1 \otimes \cdots \otimes n_k \rangle$ is a smash product functor.

**Notation 2.2.5.11.** For every finite set $I$, the collection of smash product functors $F : \mathcal{Fin}_*^I \to \mathcal{Fin}_*$ forms a category, which we will denote by $\mathcal{G}(I)$. For every pair of objects $F, G \in \mathcal{G}(I)$, there is a unique morphism from $F$ to $G$ (which is an isomorphism). Consequently, $\mathcal{G}(I)$ is equivalent to the discrete category $[0]$, consisting of the smash product functor described in Example 2.2.5.10.

**Construction 2.2.5.12.** Given a collection of $\infty$-operads $\{\mathcal{O}_i^\otimes\}_{i \in I}$, another $\infty$-operad $\mathcal{O}^\otimes$, we define a simplicial set $\text{Mul}_{\mathcal{P}Op_\infty}^\mathcal{G}(I)(\{\mathcal{O}_i^\otimes\}, \mathcal{O}^\otimes)$ equipped with a map $\text{Mul}_{\mathcal{P}Op_\infty}^\mathcal{G}(I)(\{\mathcal{O}_i^\otimes\}, \mathcal{O}^\otimes) \to N(\mathcal{G}(I))$ so that the following universal property is satisfied: for every simplicial set $K$ equipped with a map $K \to N(\mathcal{G}(I))$, there is a natural bijection of $\text{Fun}_{N(\mathcal{G}(I))}(K, \text{Mul}_{\mathcal{P}Op_\infty}^\mathcal{G}(I)(\{\mathcal{O}_i^\otimes\}, \mathcal{O}^\otimes))$ with the set of commutative diagrams
\[
\begin{array}{ccc}
K \times \prod_{i \in I} \mathcal{O}_i^\otimes & \xrightarrow{f} & \mathcal{O}^\otimes \\
\downarrow & & \downarrow \\
N(\mathcal{G}(I)) \times N(\mathcal{Fin}_*^I) & \xrightarrow{} & N(\mathcal{Fin}_*)
\end{array}
\]

having the following property: given any collection of inert morphisms $\{\alpha_i \in \text{Fun}(\Delta^1, \mathcal{O}_i^\otimes)\}_{i \in I}$ and any edge $\beta \in K$, the image $f(\beta, \{\alpha_i\})$ is an inert morphism in $\mathcal{O}^\otimes$. It is not difficult to see that the map $\text{Mul}_{\mathcal{P}Op_\infty}^\mathcal{G}(I)(\{\mathcal{O}_i^\otimes\}, \mathcal{O}^\otimes) \to N(\mathcal{G}(I))$ is a Kan fibration, whose fiber over the object $\wedge \in \mathcal{G}(I)$ (see Example 2.2.5.10) can be identified with the Kan complex of multilinear maps of $\infty$-operads
\[
\prod_{i \in I} \mathcal{O}_i^\otimes \to \mathcal{O}^\otimes
\]
2.2. CONSTRUCTIONS OF $\infty$-OPERADS

The tensor product can be identified with $\otimes_\infty$ for $\theta$-categories. Let $S_T$ described in Proposition 2.1.4.11. In view of Remark 2.1.3.8, to prove that $O$ belongs to $Op(\infty)$ are small $\infty$-operads.

Let $Op(\infty)^\otimes$ denote the operadic nerve $N^\otimes(\pi_\infty)$ (see Definition 2.1.1.23). Since the simplicial colored operad $Op_\infty^\Delta$ is fibrant (Definition 2.1.1.26), we conclude that $Op(\infty)^\otimes$ is an $\infty$-operad (Proposition 2.1.1.27).

**Proposition 2.2.5.13.** (a) The $\infty$-operad $Op(\infty)^\otimes \to N(\text{Fin}_\ast)$ of Construction 2.2.5.12 is a symmetric monoidal $\infty$-category.

(b) There is a canonical equivalence of $\infty$-categories $Op_\infty \to Op(\infty)$.

(c) The bifunctor

$$Op_\infty \times Op_\infty \simeq Op(\infty) \times Op(\infty) \overset{\otimes}{\to} Op(\infty) \simeq Op_\infty$$

is given by the tensor product construction of Definition 2.2.5.3.

(d) The unit object of $Op(\infty)$ can be identified with a fibrant replacement for the $\infty$-preoperad $\{(1)\}^\otimes$.

**Proof.** For the proof, we will borrow some results from Chapter 4. By virtue of Proposition 4.1.1.20, assertion (a) is equivalent to the statement that $Op(\infty)^\otimes \times N(\text{Fin}_\ast), \text{Ass}^\otimes$ is a monoidal $\infty$-category. This follows immediately from Example 4.1.3.18 and Variant 4.1.3.17. Assertion (b) is immediate from Example 4.1.3.18. Assertion (c) and (d) follow from Example 4.1.3.18 and the proof of Proposition 4.1.3.10.

**Remark 2.2.5.14.** It follows from Example 2.1.4.8 that the $\text{Triv}^\otimes, \ast$ can be identified with a fibrant replacement for the $\infty$-preoperad $\{(1)\}^\otimes$. It follows that the trivial $\infty$-operad $\text{Triv}^\otimes$ is a unit object of $Op(\infty)$.

We now describe the relationship between tensor products of $\infty$-operads and ordinary products of $\infty$-categories. Let $\text{Set}_\infty^\Delta$ denote the category of marked simplicial sets, equipped with the marked model structure described in §T.3.1.3. The subcategory $(\text{Set}_\infty^\Delta)^o$ of fibrant-cofibrant objects is endowed with a symmetric monoidal structure, given by the Cartesian product. We will denote the associated symmetric monoidal $\infty$-category $N^\otimes((\text{Set}_\infty^\Delta)^o)$ by $\text{Cat}_\infty^\otimes$: its underlying $\infty$-category is the $\infty$-category $\text{Cat}_\infty$ of small $\infty$-categories, and the symmetric monoidal structure is given by the formation of Cartesian products of $\infty$-categories. The construction $\otimes^\ast \to \otimes$ determines a map of simplicial colored operads $Op_\infty^\Delta \to (\text{Set}_\infty^\Delta)^o$. Passing to the operadic nerve, we get a map of $\infty$-operads $\theta : Op(\infty)^\otimes \to \text{Cat}_\infty^\otimes$.

**Proposition 2.2.5.15.** Let $Op(\infty)'$ denote the full subcategory of $Op(\infty) \simeq Op_\infty$ spanned by those $\infty$-operads $p : \otimes^\ast \to N(\text{Fin}_\ast)$ for which $p$ factors through $\text{Triv}^\otimes \subseteq N(\text{Fin}_\ast)$ (see Proposition 2.1.4.11). Then:

(a) The subcategory $Op(\infty)'$ contains the unit object of $Op(\infty)$ and is stable under tensor products. Consequently, $Op(\infty)'$ inherits a symmetric monoidal structure $Op(\infty)'^\otimes$ (Proposition 2.2.1.1).

(b) The functor $\theta$ restricts to a symmetric monoidal equivalence $Op(\infty)'^\otimes \to \text{Cat}_\infty^\otimes$.

In other words, when restricted to those $\infty$-operads which belong to the image of the fully faithful embedding $\text{Cat}_\infty \to Op_\infty$ of Proposition 2.1.4.11, the operation of tensor product recovers the usual Cartesian product of $\infty$-categories.

**Proof.** As in the proof of Proposition 2.2.5.13, it will be convenient to borrow some ideas from Chapter 4. According to Remark 2.2.5.14, the unit object of $Op(\infty)$ can be identified with $\text{Triv}^\otimes$, which obviously belongs to $Op(\infty)'$. If $\otimes^\otimes$ and $\theta^\otimes$ are $\infty$-operads belonging to $Op(\infty)'$ having tensor product $\theta^\otimes$, then $\theta^\otimes$ admits a map to the tensor product of $\text{Triv}^\otimes$ with itself. Since $\text{Triv}^\otimes$ is a unit object of $Op(\infty)'$, this tensor product can be identified with $\text{Triv}^\otimes$, so that $\theta^\otimes$ belongs to $Op(\infty)'$. This proves (a).

To prove (b), we note that $\theta$ induces an equivalence between the underlying $\infty$-categories $Op(\infty)' \to \text{Cat}_\infty$ by Proposition 2.1.4.11. In view of Remark 2.1.3.8, to prove that $\theta(\otimes^\otimes) \to N(\text{Fin}_\ast)$ and
$r : \mathcal{C}^\times \to N(\mathcal{F}_{\text{Fin}})$ be the projection maps; we wish to show that $\theta$ carries $q$-coCartesian morphisms to $r$-coCartesian morphisms. Let $q' : N^\otimes_{\text{Ass}}(\mathcal{POp}_\infty^o) \to \text{Ass}^o$ be the $\infty$-category of Example 4.1.3.18. Every $q$-coCartesian morphism in $\text{Op}(\infty)^{\otimes}$ is the image of a $q'$-coCartesian morphism in $N^\otimes_{\text{Ass}}(\mathcal{POp}_\infty^o)$ (see Example 4.1.3.18). It will therefore suffice to show that the induced map

$$N^\otimes_{\text{Ass}}(\mathcal{POp}_\infty^o) \times \text{Op}(\infty)^{\otimes} \subseteq N^\otimes_{\text{Ass}}(\mathcal{POp}_\infty^o) \to \mathcal{C}^\times$$

carries $q'$-coCartesian morphisms to $r$-coCartesian morphisms. Using the proof of Proposition 4.1.3.10, we are reduced to the following assertion:

(\ast) Let $\mathcal{O}_1^\otimes, \mathcal{O}_2^\otimes, \ldots, \mathcal{O}_n^\otimes$ be a sequence of $\infty$-operads belonging to $\text{Op}(\infty)'$, and let $f : \mathcal{O}_1^\otimes \times \cdots \times \mathcal{O}_n^\otimes \to \mathcal{O}'^\otimes$
be a map which exhibits $\mathcal{O}'^\otimes$ as a tensor product of the $\infty$-operads $\{\mathcal{O}_i^\otimes\}_{1 \leq i \leq n}$. Then $f$ induces an equivalence of $\infty$-categories $\mathcal{O}_1 \times \cdots \times \mathcal{O}_n \to \mathcal{O}'$.

For each index $i$, we let $\mathcal{O}_i^\natural$ denote the marked simplicial set $(\mathcal{O}_i, M_i)$, where $M_i$ is the collection of equivalences in $\mathcal{O}_i$. We claim that the inclusion $\phi : \mathcal{O}_1^\natural \hookrightarrow \mathcal{O}_1^\otimes$ is a weak equivalence of $\infty$-preoperads. To prove this, it suffices to show that for any $\infty$-operad $\mathcal{C}^\otimes$, composition with $\phi$ induces a homotopy equivalence

$$\text{Map}_{\mathcal{POp}_\infty}(\mathcal{O}_1^\natural, \mathcal{C}^\otimes) \to \text{Map}_{\mathcal{POp}_\infty}(\mathcal{O}_1^\otimes, \mathcal{C}^\otimes).$$

Without loss of generality, we may replace $\mathcal{C}^\otimes$ by $\mathcal{C}^\otimes \times_{N(\mathcal{F}_{\text{Fin}})} \text{Triv}^\otimes$ (this does not change either of the relevant mapping spaces), and thereby reduce to Proposition 2.1.4.11.

The hypothesis that $\alpha$ exhibits $\mathcal{O}'^\otimes$ as a tensor product of the $\infty$-operads $\mathcal{O}_i^\otimes$ is equivalent to the requirement that $\alpha$ induces a weak equivalence of $\infty$-preoperads

$$\mathcal{O}_1^\otimes \otimes \cdots \otimes \mathcal{O}_n^\otimes \to \mathcal{O}'^\otimes.$$

It follows that the induced map $\alpha : \prod_i \mathcal{O}_i^\otimes \to \mathcal{O}'^\otimes$ is a weak equivalence of $\infty$-preoperads. According to Proposition 2.1.4.11, there exists a map of $\infty$-operads $\mathcal{C}^\otimes \to \text{Triv}^\otimes$ and an equivalence of $\infty$-categories $\prod_i \mathcal{O}_i \to \mathcal{C}$. The above argument shows that $\alpha$ induces a weak equivalence of $\infty$-preoperads $\beta : \prod_i \mathcal{O}_i^\natural \to \mathcal{C}^\otimes$.

In particular, the map $\alpha$ can be factored as a composition

$$\prod_i \mathcal{O}_i^\natural \overset{\beta}{\to} \mathcal{C}^\otimes \overset{\gamma}{\to} \mathcal{O}'^\otimes.$$

Since $\alpha$ and $\beta$ are weak equivalences, we conclude that $\gamma$ is a weak equivalence between fibrant objects of $\mathcal{POp}_\infty$: that is, $\gamma$ induces an equivalence of $\infty$-operads $\mathcal{C}^\otimes \to \mathcal{O}'^\otimes$. In particular, the underlying map of $\infty$-categories $\mathcal{C} \to \mathcal{O}'$ is a categorical equivalence. It follows that the composite functor $\prod_i \mathcal{O}_i \to \mathcal{C} \to \mathcal{O}'$ is also an equivalence, as desired.

\section{Disintegration and Assembly}

Let $A$ be an associative ring. Recall that an \emph{involution} on $A$ is a map $\sigma : A \to A$ satisfying the conditions

$$(a + b)^\sigma = a^\sigma + b^\sigma \quad (ab)^\sigma = b^\sigma a^\sigma \quad (a^\sigma)^\sigma = a;$$

here $a^\sigma$ denotes the image of $a$ under the map $\sigma$. Let $\text{Ring}$ denote the category of associative rings, and let $\text{Ring}^\sigma$ denote the category of associative rings equipped with an involution (whose morphisms are ring homomorphisms that commute with the specified involutions). To understand the relationship between these two categories, we observe that the construction $A \mapsto A^{op}$ defines an action of the symmetric group $\Sigma_2$ on the category $\text{Ring}$. The category $\text{Ring}^\sigma$ can be described as the category of (homotopy) fixed points for the action of $\Sigma_2$ on $\text{Ring}$. In particular, we can reconstruct the category $\text{Ring}^\sigma$ by understanding the category $\text{Ring}$ together with its action of $\Sigma_2$. \hfill $\blacksquare$
2.3. DISINTEGRATION AND ASSEMBLY

The category Ring can be described as the category of algebras over the associative operad $\mathcal{O}$ in the (symmetric monoidal) category of abelian groups. Similarly, we can describe Ring as the category of $\mathcal{O}'$-algebra objects in the category of abelian groups, where $\mathcal{O}'$ is a suitably defined enlargement of the associative operad. The relationship between Ring and Ring reflects a more basic relationship between the operads $\mathcal{O}$ and $\mathcal{O}'$: namely, the operad $\mathcal{O}$ carries an action of the group $\Sigma_2$, and the operad $\mathcal{O}'$ can be recovered as a kind of semidirect product $\mathcal{O} \rtimes \Sigma_2$. This assertion is useful because $\mathcal{O}$ is, in many respects, simpler than $\mathcal{O}'$. For example, the operad $\mathcal{O}$ has only a single unary operation (the identity) while $\mathcal{O}'$ has a pair of unary operations (the identity and the involution).

In this section, we will describe a generalization of this phenomenon. We begin in §2.3.1 by introducing the notion of a unital $\infty$-operad. Roughly speaking, an $\infty$-operad $\mathcal{O}^\otimes$ is unital if it has a unique nullary operation (more precisely, if it has a unique nullary operation for each object of the $\infty$-category $\mathcal{O}$; see Definition 2.3.1.1). Many of $\infty$-operads which arise naturally are unital, and nonunital $\infty$-operads can be replaced by unital $\infty$-operads via the process of unitalization (Definition 2.3.1.10). We say that a unital $\infty$-operad $\mathcal{O}^\otimes$ is reduced if the $\infty$-category $\mathcal{O}$ is a contractible Kan complex. In §2.3.4, we will show that if $\mathcal{O}^\otimes$ is any unital $\infty$-operad whose underlying $\infty$-category $\mathcal{O}$ is a Kan complex, then $\mathcal{O}^\otimes$ can be “assembled” from a family of reduced $\infty$-operads parametrized by $\mathcal{O}$ (Theorem 2.3.4.4). A precise formulation of this assertion requires the notion of a generalized $\infty$-operad, which we discuss in §2.3.2. The proof will require a somewhat technical criterion for detecting weak equivalences of $\infty$-preoperads, which we discuss in §2.3.3.

Remark 2.3.0.1. The assembly process described in §2.3.4 can be regarded as a generalization of the semidirect product construction mentioned above, and will play an important role in §5.4.2.

2.3.1 Unital $\infty$-Operads

Let $\mathcal{O}^\otimes$ be an $\infty$-operad. Then for every $n$-tuple of objects $\{X_i\}_{1 \leq i \leq n}$ in $\mathcal{O}$ and every object $Y \in \mathcal{O}$, we can consider the mapping space $\text{Mul}_\mathcal{O}(\{X_i\}, Y)$ defined in Notation 2.1.1.16. We can think of this as the space of $n$-ary operations (taking inputs of type $\{X_i\}_{1 \leq i \leq n}$ and producing an output of type $Y$) in $\mathcal{O}^\otimes$. In general, these operation spaces are related to one another via very complicated composition laws. When $n = 1$ the situation is dramatically simpler: the 1-ary operation spaces $\text{Mul}_\mathcal{O}(\{X\}, Y)$ are simply the mapping spaces $\text{Map}_\mathcal{O}(X, Y)$ in the underlying $\infty$-category $\mathcal{O}$. In this section, we will consider what is in some sense an even more basic invariant of $\mathcal{O}^\otimes$: namely, the structure of the nullary operation spaces $\text{Mul}_\mathcal{O}(\emptyset, Y)$. More precisely, we will be interested in the situation where this invariant is trivial:

Definition 2.3.1.1. We will say that an $\infty$-operad $\mathcal{O}^\otimes$ is unital if, for every object $X \in \mathcal{O}$, the space $\text{Mul}_\mathcal{O}(\emptyset, X)$ is contractible.

Warning 2.3.1.2. In the literature, the term unital operad is used with two very different meanings:

(i) To describe an operad $\{\mathcal{O}_n\}_{n \geq 0}$ which has a distinguished unary operation $\text{id} \in \mathcal{O}_1$, which is a left and right unit with respect to composition.

(ii) To describe an operad $\{\mathcal{O}_n\}_{n \geq 0}$ which has a unique nullary operation $e \in \mathcal{O}_0$.

Definition 2.3.1.1 should be regarded as an $\infty$-categorical generalization of (ii); the analogue of condition (i) is built-in to our definition of an $\infty$-operad.

Example 2.3.1.3. The $\infty$-operads $\text{Comm}^\otimes$ and $\mathcal{E}_0^\otimes$ of Examples 2.1.1.18 and 2.1.1.19 are unital. The trivial $\infty$-operad of Example 2.1.1.20 is not unital.

Here is a purely categorical description of the class of unital $\infty$-operads:

Proposition 2.3.1.4. Let $\mathcal{O}^\otimes$ be an $\infty$-operad. The following conditions are equivalent:

1. The $\infty$-category $\mathcal{O}^\otimes$ is pointed (that is, there exists an object of $\mathcal{O}^\otimes$ which is both initial and final).

2. The $\infty$-operad $\mathcal{O}^\otimes$ is unital.
The proof depends on the following observation:

**Lemma 2.3.1.5.** Let $p : O^0 \to N(Fin_\ast)$ be an $\infty$-operad. Then an object $X$ of the $\infty$-category $O^0$ is final if and only if $p(X) = (0)$. Moreover, there exists an object of $O^0$ satisfying this condition.

**Proof.** Since $O^0$ is an $\infty$-operad, we have an equivalence $O^0 \simeq O^0 \simeq \Delta^0$; this proves the existence of an object $X \in O^0$ such that $p(X) = (0)$. Since $O^0$ is an $\infty$-operad, the object $X \in O^0$ is $p$-final. Since $p(X) = (0)$ is a final object of $N(Fin_\ast)$, it follows that $X$ is a final object of $O^0$.

To prove the converse, suppose that $X'$ is any final object of $O^0$. Then $X' \simeq X$ so that $p(X') \simeq (0)$. It follows that $p(X') = (0)$, as desired.

**Proof of Proposition 2.3.1.4.** According to Lemma 2.3.1.5, the $\infty$-category $O^0$ admits a final object $Y$. Assertion (1) is equivalent to the requirement that $Y$ is also initial: that is, that the space $\text{Map}_{O^0}(Y, X)$ is contractible for every $X \in O^0$. Let $(n)$ denote the image of $X$ in $N(Fin_\ast)$, and choose inert morphisms $X \to X_i$ covering $p^i : (n) \to (1)$ for $1 \leq i \leq n$. Since $X$ is a $p$-limit of the diagram $\{X_i\}_{1 \leq i \leq n} \to O^0$, we conclude that $\text{Map}_{O^0}(Y, X) \cong \prod_{1 \leq i \leq n} \text{Map}_{O^0}(Y, X_i)$. Assertion (1) is therefore equivalent to the requirement that $\text{Map}_{O^0}(Y, X)$ is contractible for $X \in O$, which is a rewording of condition (2).

The class of unital $\infty$-operads also has a natural characterization in terms of the tensor product of $\infty$-operads (see §2.2.5). If $\alpha : (m) \to (m')$ and $\beta : (n) \to (n')$ are morphisms in $N(Fin_\ast)$ and $\gamma = \alpha \land \beta : (mn) \to (m'n')$ is the induced map, then $\gamma^{-1}(an + b - n) \simeq \alpha^{-1}\{a\} \times \beta^{-1}\{b\}$. In particular, if each of the fibers $\alpha^{-1}\{a\}$ and $\beta^{-1}\{b\}$ has cardinality $\leq 1$, then each fiber of $\gamma$ has cardinality $\leq 1$. It follows that $\land$ induces a map $f : E_0^0 \times E_0^0 \to E_0^0$, where $E_0^0 \subseteq N(Fin_\ast)$ is the $\infty$-operad defined in Example 2.1.1.19.

**Proposition 2.3.1.6.** The map $f : E_0^0 \times E_0^0 \to E_0^0$ is a bifunctor of $\infty$-operads, which exhibits $E_0^0$ as a tensor product of $E_0^0$ with itself.

**Proof.** Consider the map $g : \Delta^1 \to E_0$ determined by the morphism $(0) \to (1)$ in $Fin_\ast$. Example 2.1.4.9 asserts that $g$ induces a weak equivalence of $\infty$-operads $\Delta^1 \to E_0^0$. We can factor the weak equivalence $g$ as a composition

$$\Delta^1 \xrightarrow{\delta} (\Delta^1)^{\triangleright} \simeq (\Delta^1)^{\triangleright} \bigotimes E_0^0 \otimes E_0^0 \xrightarrow{\gamma} E_0^0,$$

where $\delta$ is the diagonal map. The map $g \circ \delta$ is a weak equivalence of $\infty$-operads. By a two-out-of-three argument, we are reduced to proving that the diagonal $\Delta^1 \to (\Delta^1)^{\triangleright} \simeq (\Delta^1)^{\triangleright} \otimes (\Delta^1)^{\triangleright}$ is a weak equivalence of $\infty$-operads.

Unwinding the definitions, it suffices to show the following: for every $\infty$-operad $p : O^0 \to N(Fin_\ast)$, composition with $\delta$ induces a trivial Kan fibration

$$\text{Fun}_{N(Fin_\ast)}(\Delta^1 \times \Delta^1, O^0) \to \text{Fun}_{N(Fin_\ast)}(\Delta^1, O^0).$$

This follows from Proposition T.4.3.2.15, since every functor $F \in \text{Fun}_{N(Fin_\ast)}(\Delta^1 \times \Delta^1, O^0)$ is a $p$-left Kan extension of $F \circ \delta$ (because every morphism in $O^0 \otimes (0)$ is an equivalence).

**Corollary 2.3.1.7.** Let $i : \{0\} \to E_0^0$ denote the inclusion. Then composition with $i$ induces weak equivalences of $\infty$-operads

$$E_0^0 \simeq E_0^0 \otimes \{0\} \to E_0^0 \otimes E_0^0,$$

$$E_0^0 \simeq \{0\} \otimes E_0^0 \to E_0^0 \otimes E_0^0.$$

**Corollary 2.3.1.8.** Let $Op_\infty$ denote the $\infty$-category of (small) $\infty$-operads, which we identify with the underlying $\infty$-category $N(POP_\infty)$ of the simplicial monoidal model category $POP_\infty$. Let $U : Op_\infty \to Op_\infty$ be induced by the left Quillen functor $X \mapsto X \otimes E_0^0$. Then $U$ is a localization functor from $Op_\infty$ to itself.
2.3. DISINTEGRATION AND ASSEMBLY

**Proposition 2.3.1.9.** Let $\mathcal{O}^\circ$ be an $\infty$-operad. The following conditions are equivalent:

1. The $\infty$-operad $\mathcal{O}^\circ$ is unital.
2. The $\infty$-operad $\mathcal{O}^\circ$ belongs to the essential image of the localization functor $U : \mathcal{O}_\infty \to \mathcal{O}_\infty$ of Corollary 2.3.1.8.

**Proof.** We first show that (1) implies (2). Let $\alpha : \mathcal{O}^\circ \to U \mathcal{O}^\circ$ be a morphism in $\mathcal{O}_\infty$ which exhibits $U \mathcal{O}^\circ$ as a $U$-localization of $\mathcal{O}^\circ$ (so that $U \mathcal{O}^\circ$ is a tensor product of $\mathcal{O}^\circ$ with $E_0^{\mathcal{O}^\circ}$). We will prove that there exists a morphism $\beta : U \mathcal{O}^\circ \to \mathcal{O}^\circ$ such that $\beta \circ \alpha$ is equivalent to $\text{id}_{\mathcal{O}^\circ}$. We claim that $\beta$ is a homotopy inverse to $\alpha$: to prove this, it suffices to show that $\alpha \circ \beta$ is homotopic to the identity $\text{id}_{U \mathcal{O}^\circ}$. Since $U \mathcal{O}^\circ$ is $U$-local and $\alpha$ is a $U$-equivalence, it suffices to show that $\alpha \circ \beta \circ \alpha$ is homotopic to $\alpha$, which is clear.

To construct the map $\beta$, we observe that $U \mathcal{O}^\circ$ can be identified with a fibrant replacement for the object $\mathcal{O}^\circ \otimes (\Delta^1)^p \in \mathcal{O}_\infty$ (here we regard $(\Delta^1)^p$ as an $\infty$-preoperad as in the proof of Proposition 2.3.1.6). It will therefore suffice to construct a map $h : \mathcal{O}^\circ \times \Delta^1 \to \mathcal{O}^\circ$ such that $h|((\mathcal{O}^\circ \times \{1\}) = \text{id}_{\mathcal{O}^\circ}$ and $h|((\mathcal{O}^\circ \times \{0\})$ factors through $\mathcal{O}^\circ_0$. The existence of $h$ follows immediately the fact that $\mathcal{O}^\circ$ is a pointed $\infty$-category (Proposition 2.3.1.4).

To show that (2) $\Rightarrow$ (1), we reverse the above reasoning: if $\mathcal{O}^\circ$ is $U$-local, then there exists a morphism $\beta : U \mathcal{O}^\circ \to \mathcal{O}^\circ$ which is right inverse to $\alpha$, which is equivalent to the existence of a map $h : \mathcal{O}^\circ \times \Delta^1 \to \mathcal{O}^\circ$ as above. We may assume without loss of generality that $h|((\mathcal{O}^\circ \times \{1\}) = \text{id}_{\mathcal{O}^\circ}$ and $h|((\mathcal{O}^\circ \times \{0\})$ factors through $\mathcal{O}^\circ_0$. Then $h$ can be regarded as a section of the left fibration $(\mathcal{O}^\circ)^{X/} \to \mathcal{O}^\circ$. This proves that $X$ is an initial object of $\mathcal{O}^\circ$. Since $X$ is also a final object of $\mathcal{O}^\circ$, we deduce that $\mathcal{O}^\circ$ is pointed as an $\infty$-category and therefore unital as an $\infty$-operad (Proposition 2.3.1.4).

It follows from Proposition 2.3.1.9 that the full subcategory of $\mathcal{O}_\infty$ spanned by the unital $\infty$-operads is a localization of $\mathcal{O}_\infty$. Our next goal is to show that this subcategory is also a colocalization of $\mathcal{O}_\infty$.

**Definition 2.3.1.10.** Let $f : \mathcal{O}^\circ \to \mathcal{O}^\circ$ be a map of $\infty$-operads. We will say that $f$ exhibits $\mathcal{O}^\circ$ as a unitalization of $\mathcal{O}^\circ$ if the following conditions are satisfied:

1. The $\infty$-operad $\mathcal{O}^\circ$ is unital.
2. For every unital $\infty$-operad $\mathcal{E}^\circ$, composition with $f$ induces an equivalence of $\infty$-categories $\text{Alg}_{\mathcal{E}}(\mathcal{O}^\circ) \to \text{Alg}_{\mathcal{E}}(\mathcal{O})$.

It is clear that if an $\infty$-operad $\mathcal{O}^\circ$ admits a unitalization $\mathcal{O}^\circ$, then $\mathcal{O}^\circ$ is determined uniquely up to equivalence. We now prove the existence of $\mathcal{O}^\circ$ by means of a simple explicit construction.

**Proposition 2.3.1.11.** Let $\mathcal{O}^\circ$ be an $\infty$-operad, and let $\mathcal{O}^\circ_*$ be the $\infty$-category of pointed objects of $\mathcal{O}^\circ$. Then:

1. The forgetful map $p : \mathcal{O}^\circ_* \to \mathcal{O}^\circ$ is a fibration of $\infty$-operads (in particular, $\mathcal{O}^\circ_*$ is an $\infty$-operad).
2. The $\infty$-operad $\mathcal{O}^\circ_*$ is unital.
3. For every unital $\infty$-operad $\mathcal{E}^\circ$, composition with $p$ induces a trivial Kan fibration $\theta : \text{Alg}_{\mathcal{E}}(\mathcal{O}^\circ_*) \to \text{Alg}_{\mathcal{E}}(\mathcal{O})$ (here $\text{Alg}_{\mathcal{E}}(\mathcal{O}^\circ_*)$ denotes the $\infty$-category of $\mathcal{E}$-algebra objects in the $\infty$-operad $\mathcal{O}^\circ_*$).
4. The map $p$ exhibits $\mathcal{O}^\circ_*$ as a unitalization of the $\infty$-operad $\mathcal{O}^\circ$.

**Lemma 2.3.1.12.** Let $\mathcal{E}$ be a pointed $\infty$-category, and let $\mathcal{D}$ be an $\infty$-category with a final object. Let $\text{Fun}^*(\mathcal{E}, \mathcal{D})$ be the full subcategory of $\text{Fun}(\mathcal{E}, \mathcal{D})$ spanned by those functors which preserve final objects, and let $\text{Fun}^*(\mathcal{E}, \mathcal{D}_*)$ be defined similarly. Then the forgetful functor

$$
\text{Fun}^*(\mathcal{E}, \mathcal{D}_*) \to \text{Fun}^*(\mathcal{E}, \mathcal{D})
$$

is a trivial Kan fibration.
Proof. Let $\mathcal{E} \subseteq \mathcal{C} \times \Delta^1$ be the full subcategory spanned by objects $(C, i)$, where either $C$ is a zero object of $\mathcal{C}$ or $i = 1$. Let $\text{Fun}'(\mathcal{E}, \mathcal{D})$ be the full subcategory of $\text{Fun}(\mathcal{E}, \mathcal{D})$ spanned by those functors $F$ such that $F(C, i)$ is a final object of $\mathcal{D}$, whenever $C \in \mathcal{C}$ is a zero object. We observe that a functor $F \in \text{Fun}(\mathcal{E}, \mathcal{D})$ belongs to $\text{Fun}'(\mathcal{E}, \mathcal{D})$ if and only if $F_0 = F|_{C \times \{1\}}$ belongs to $\text{Fun}'(\mathcal{E}, \mathcal{D})$, and $F$ is a right Kan extension of $F_0$. We can identify $\text{Fun}'(\mathcal{E}, \mathcal{D}_*)$ with the full subcategory of $\text{Fun}(\mathcal{E} \times \Delta^1, \mathcal{D})$ spanned by those functors $G$ such that $G_0 = G|_{\mathcal{E} \times \{0\}} \in \text{Fun}'(\mathcal{E}, \mathcal{D})$ and $G$ is a left Kan extension of $G_0$. It follows from Proposition T.4.3.2.15 that the restriction maps

$$\text{Fun}'(\mathcal{E}, \mathcal{D}_*) \to \text{Fun}'(\mathcal{E}, \mathcal{D}) \to \text{Fun}'(\mathcal{E}, \mathcal{D})$$

are trivial Kan fibrations, so that their composition is a trivial Kan fibration as desired. \qed

Proof of Proposition 2.3.1.11. We first prove (1). Fix an object $X_* \in \mathcal{O}^\odot_\odot$ lying over $X \in \mathcal{O}^\odot$, and let $\alpha : X \to Y$ be an inert morphism in $\mathcal{O}^\odot$. Since the map $q : \mathcal{O}^\odot_\odot \to \mathcal{O}^\odot$ is a left fibration, we can lift $\alpha$ to a morphism $X_* \to Y_*$, which is automatically $q$-coCartesian. Let $\langle n \rangle$ denote the image of $X$ in $\mathcal{F}_{\text{In}}$, and choose inert morphisms $\alpha^i : X \to X^i$ covering the maps $\rho^i : \langle n \rangle \to \langle i \rangle$ for $1 \leq i \leq n$. We claim that the induced functors $\alpha^i_!$ induce an equivalence $(\mathcal{O}^\odot_\odot)_X \to \prod_{1 \leq i \leq n}(\mathcal{O}^\odot_\odot)_{X^i}$. Fix a final object 1 in $\mathcal{O}^\odot$, so that $\mathcal{O}^\odot$ is equivalent to $\mathcal{O}^\odot_1$. The desired assertion is not equivalent to the assertion that the maps $\alpha^i$ induce a homotopy equivalence

$$\text{Map}_{\mathcal{O}^\odot}(1, X) \to \prod_{1 \leq i \leq n} \text{Map}_{\mathcal{O}^\odot}(1, X_i),$$

which follows immediately from our assumptions that $\mathcal{O}^\odot$ is an $\infty$-operad and that each $\alpha^i$ is inert.

To complete the proof that $p$ is an $\infty$-operad fibration, let $X_*$ be as above, let $\langle n \rangle$ be its image in $\mathcal{F}_{\text{In}}$, and suppose we have chosen morphisms $X_* \to X^i_*$ in $\mathcal{O}^\odot_\odot$ whose images in $\mathcal{O}^\odot$ are inert and which cover the inert morphisms $\rho^i : \langle n \rangle \to \langle 1 \rangle$ for $1 \leq i \leq n$; we wish to show that the induced diagram $\delta : \langle n \rangle^\odot \to \mathcal{O}^\odot_\odot$ is a $p$-limit diagram. Let $\delta = \overline{\delta}(\langle n \rangle^\odot)$; we wish to prove that the map

$$(\mathcal{O}^\odot_\odot)/\overline{\delta} \to (\mathcal{O}^\odot_\odot)/\delta \times_{\mathcal{O}^\odot_\odot/p\overline{\delta}} \mathcal{O}^\odot_\odot$$

is a trivial Kan fibration. Since $\mathcal{O}^\odot_\odot$ is equivalent to $\mathcal{O}^\odot_1$, this is equivalent to the requirement that every extension problem of the form

$$(\partial \Delta^m \star \langle n \rangle^\odot, f) \to (\mathcal{O}^\odot_\odot)$$

admits a solution, provided that $m \geq 2$, $f$ carries the initial vertex of $\Delta^m$ to 1 $\in \mathcal{O}^\odot$, and $f|\{m\} \star \langle n \rangle^\odot = p \circ \overline{\delta}$. Let $\pi : \mathcal{O}^\odot \to N(\mathcal{F}_{\text{In}})$. The map $\pi \circ f$ admits a unique extension to $\Delta^m \star \langle n \rangle^\odot$; this is obvious if $m > 2$, and for $m = 2$ it follows from the observation that $\pi(1) = (0)$ is an initial object of $N(\mathcal{F}_{\text{In}})$. The solubility of the relevant lifting problem now follows from the observation that $p \circ \overline{\delta}$ is a $\pi$-limit diagram.

Assertion (2) is clear (since $\mathcal{O}^\odot_\odot$ has a zero object), assertion (3) follows from the observation that $\theta$ is a pullback of the morphism $\text{Fun}'(\mathcal{C}^\odot, \mathcal{O}^\odot) \to \text{Fun}'(\mathcal{C}^\odot, \mathcal{O}^\odot)$ described in Lemma 2.3.1.12, and assertion (4) follows immediately from (2) and (3). \qed

We conclude this section with two results concerning the behavior of unitalization in families.

Proposition 2.3.1.13. Let $p : \mathcal{C}^\odot \to \mathcal{O}^\odot$ be a coCartesian fibration of $\infty$-operads, where $\mathcal{O}^\odot$ is unital. The following conditions are equivalent:

1. The $\infty$-operad $\mathcal{C}^\odot$ is unital.

2. For every object $X \in \mathcal{C}$, the unit object of $\mathcal{C}_X$ (see §3.2.1) is initial in $\mathcal{C}_X$. 
2.3. DISINTEGRATION AND ASSEMBLY

Proof. Choose an object \( 1 \in \mathcal{C} \). Assertion (1) is equivalent to the requirement that \( 1 \) be an initial object of \( \mathcal{C} \). Since \( p(1) \) is an initial object of \( \mathcal{O} \), this is equivalent to the requirement that \( \emptyset \) is \( p \)-initial (Proposition T.4.3.1.5). Since \( p \) is a coCartesian fibration, (1) is equivalent to the requirement that for every morphism \( \beta : p(1) \to X \) in \( \mathcal{O} \), the object \( \beta(1) \) is an initial object of \( \mathcal{C} \) (Proposition T.4.3.1.10). Write \( X = \bigoplus X_i \), where each \( X_i \in \mathcal{O} \). Using the equivalence \( \mathcal{C}_{X} \simeq \prod_i \mathcal{C}_{X_i} \), we see that it suffices to check this criterion when \( X \in \mathcal{O} \), in which case we are reduced to assertion (2). \( \square \)

Proposition 2.3.1.14. Let \( p : \mathcal{C} \to \mathcal{O} \) be a coCartesian fibration of \( \infty \)-operads, where \( \mathcal{O} \) is unital. Then:

1. Let \( q : \mathcal{C} \to \mathcal{O} \) be a categorical fibration which exhibits \( \mathcal{C} \) as a unitalization of \( \mathcal{O} \). Then the map \( p \circ q : \mathcal{C} \to \mathcal{O} \) is a coCartesian fibration of \( \infty \)-operads.

2. For every map of unital \( \infty \)-operads \( \mathcal{O} \to \mathcal{O} \), the map \( q \) induces an equivalence of \( \infty \)-categories \( \mathcal{O} \to \mathcal{O} \).

Proof. By virtue of Proposition 2.3.1.11, we may assume without loss of generality that \( \mathcal{C} = \mathcal{O} \). In this case, the map \( p \circ q \) factors as a composition \( \mathcal{C} \to \mathcal{O} \to \mathcal{O} \). The functor \( \mathcal{C} \to \mathcal{O} \) is equivalent to \( \mathcal{O}_{1/} \to \mathcal{O}_{p(1)/} \), where \( 1 \in \mathcal{O}_{(0)} \) is a final object of \( \mathcal{O} \), and therefore a coCartesian fibration (Proposition T.2.4.3.1), and the map \( \mathcal{O} \to \mathcal{O} \) is a trivial Kan fibration by virtue of our assumption that \( \mathcal{O} \) is unital. This proves (1). To prove (2), it suffices to observe that \( \theta \) is a pullback of the map \( \mathcal{O} \to \mathcal{O} \), which is a trivial Kan fibration by Proposition 2.3.1.11 (here \( \mathcal{C} \) denotes the underlying \( \infty \)-category of the \( \infty \)-operad \( \mathcal{C} \), which is generally not the \( \infty \)-category of pointed objects of \( \mathcal{C} \)). \( \square \)

2.3.2 Generalized \( \infty \)-Operads

Let \( \mathcal{O} \) be an \( \infty \)-operad. Then, for each \( n \geq 0 \), we have a canonical equivalence of \( \infty \)-categories \( \mathcal{O}_{(n)} \simeq \mathcal{O} \). In particular, the \( \infty \)-category \( \mathcal{O}_{(0)} \) is a contractible Kan complex. In this section, we will introduce the notion of a \( \infty \)-operad (Definition 2.3.2.1), where we relax the assumption that \( \mathcal{O}_{(0)} \) is contractible, and replace the absolute \( n \)-th power \( \mathcal{O} \) with the \( n \)-th fiber power over the \( \infty \)-category \( \mathcal{O} \). We will also introduce the closely related notion of a \( \mathcal{O} \)-family of \( \infty \)-operads, where \( \mathcal{O} \) is an \( \infty \)-category (Definition 2.3.2.10). We will see that giving a generalized \( \infty \)-operad \( \mathcal{O} \) is equivalent to giving an \( \infty \)-category \( \mathcal{C} \) (which can be identified with \( \mathcal{O}_{(0)} \) and a \( \mathcal{O} \)-family of \( \infty \)-operads.

Definition 2.3.2.1. A generalized \( \infty \)-operad is an \( \infty \)-category \( \mathcal{O} \) equipped with a map \( q : \mathcal{O} \to N(\mathcal{F}_{\mathcal{O}}) \) satisfying the following conditions:

1. For every object \( X \in \mathcal{O} \) and every inert morphism \( \alpha : p(X) \to \langle n \rangle \), there exists a \( q \)-coCartesian morphism \( \pi : X \to Y \) with \( q(\pi) = \alpha \).

2. Suppose we are given a commutative diagram \( \sigma \):

\[
\begin{array}{ccc}
\langle m \rangle & \rightarrow & \langle n \rangle \\
\downarrow & & \downarrow \\
\langle m' \rangle & \rightarrow & \langle n' \rangle
\end{array}
\]

in \( \mathcal{F}_{\mathcal{O}} \), which consists of inertmorphisms and induces a bijection of finite sets \( \langle m' \rangle^\circ \prod_{\langle n' \rangle^\circ} \langle n \rangle^\circ \rightarrow \langle m \rangle^\circ \). Then the induced diagram

\[
\begin{array}{ccc}
\mathcal{O}_{\langle m \rangle} & \rightarrow & \mathcal{O}_{\langle n \rangle} \\
\downarrow & & \downarrow \\
\mathcal{O}_{\langle m' \rangle} & \rightarrow & \mathcal{O}_{\langle n' \rangle}
\end{array}
\]
is a pullback square of $\infty$-categories.

(3) Let $\sigma$ be as in (2), and suppose that $\sigma$ can be lifted to a diagram $\tilde{\sigma}$

$$
\begin{array}{ccc}
X & \longrightarrow & Y \\
\downarrow & & \downarrow \\
X' & \longrightarrow & Y'
\end{array}
$$

consisting of $q$-coCartesian morphisms in $\mathcal{O}^\otimes$. The $\tilde{\sigma}$ is a $q$-limit diagram.

**Definition 2.3.2.2.** Let $q : \mathcal{O}^\otimes \rightarrow N(\mathcal{F}\text{in}_*)$ be a generalized $\infty$-operad. We will say that a morphism $\alpha$ in $\mathcal{O}^\otimes$ is **inert** if $q(\alpha)$ is an inert morphism in $\mathcal{F}\text{in}_*$ and $\alpha$ is $q$-coCartesian. We let $\mathcal{O}^{\otimes,\natural}$ denote the marked simplicial set $(\mathcal{O}^\otimes, M)$, where $M$ is the collection of all inert morphisms in $\mathcal{O}^\otimes$.

If $\mathcal{O}^\otimes$ and $\mathcal{O}'^\otimes$ are generalized $\infty$-operads, then we will say that a morphism of simplicial sets $f : \mathcal{O}^\otimes \rightarrow \mathcal{O}'^\otimes$ is a **map of generalized $\infty$-operads** if the following conditions are satisfied:

(a) The diagram

$$
\begin{array}{ccc}
\mathcal{O}^\otimes & \longrightarrow & \mathcal{O}'^\otimes \\
\downarrow & & \downarrow \\
N(\mathcal{F}\text{in}_*) & \longrightarrow & N(\mathcal{F}\text{in}_*)
\end{array}
$$

commutes.

(b) The map $f$ carries inert morphisms in $\mathcal{O}^\otimes$ to inert morphisms in $\mathcal{O}'^\otimes$.

We let $\text{Alg}_{\mathcal{O}}(\mathcal{O}')$ denote the full subcategory of $\text{Fun}_{N(\mathcal{F}\text{in}_*)}(\mathcal{O}^\otimes, \mathcal{O}'^\otimes)$ spanned by the maps of generalized $\infty$-operads.

**Variant 2.3.2.3.** Given a categorical fibration of generalized $\infty$-operads $\mathcal{C}^\otimes \rightarrow \mathcal{O}^\otimes$ and a map $\alpha : \mathcal{O}'^\otimes \rightarrow \mathcal{O}^\otimes$, we let $\text{Alg}_{\mathcal{O}'}/\mathcal{O}(\mathcal{C})$ denote the fiber of the induced map $\text{Alg}_{\mathcal{O}'}(\mathcal{C}) \rightarrow \text{Alg}_{\mathcal{O}'}(\mathcal{O})$ over the vertex $\alpha$. If $\mathcal{O}'^\otimes = \mathcal{O}^\otimes$ and $\alpha$ is the identity map, we let $\text{Alg}_{/\mathcal{O}}(\mathcal{C})$ denote the $\infty$-category $\text{Alg}_{\mathcal{O}'}/\mathcal{O}(\mathcal{C})$.

**Remark 2.3.2.4.** Let $\mathcal{O}p_{\infty}$ be the category of $\infty$-preoperads (Definition 2.1.4.2). There exists a left proper combinatorial simplicial model structure on the category $\mathcal{O}p_{\infty}$ with the following properties:

(1) A morphism $\alpha : \langle \mathcal{X} \rangle \rightarrow \langle \mathcal{Y} \rangle$ in $\mathcal{O}p_{\infty}$ is a cofibration if and only if the underlying map of simplicial sets $\langle X \rangle \rightarrow \langle Y \rangle$ is a monomorphism.

(2) An object $\langle \mathcal{X} \rangle$ in $\mathcal{O}p_{\infty}$ is fibrant if and only if it has the form $\mathcal{O}^{\otimes,\natural}$, for some generalized $\infty$-operad $\mathcal{O}^\otimes$.

We will refer to this model structure on $\mathcal{O}p_{\infty}$ as the **generalized $\infty$-operadic model structure**.

To verify the existence (and uniqueness) of this model structure, we apply Theorem B.0.20 to the categorical pattern $\mathfrak{P} = (M, T, \{\sigma_\alpha : \Delta^1 \times \Delta^1 \rightarrow \mathcal{O}^\otimes\}_{\alpha \in A})$ on $N(\mathcal{F}\text{in}_*)$, where $M$ is the collection of inert morphisms in $N(\mathcal{F}\text{in}_*)$, $T$ is the collection of all 2-simplices of $N(\mathcal{F}\text{in}_*)$, and $A$ is the collection of all diagrams

$$
\begin{array}{ccc}
\langle m \rangle & \longrightarrow & \langle n \rangle \\
\downarrow & & \downarrow \\
\langle m' \rangle & \longrightarrow & \langle n' \rangle
\end{array}
$$

consisting of inert morphisms which induce a bijection $\langle m' \rangle^\circ \coprod_{\langle n' \rangle^\circ} \langle n \rangle^\circ \rightarrow \langle m \rangle^\circ$. Moreover, Proposition B.2.7 implies the following additional property:
Proposition 2.1.4. Let the identity functor $B$ be a map of simplicial sets. The following conditions are equivalent:

1. The map $p$ exhibits $\mathcal{O}$ as a generalized $\infty$-operad, and the fiber $\mathcal{O}(0)$ is a contractible Kan complex.

2. The map $p$ exhibits $\mathcal{O}$ as an $\infty$-operad.

Proposition 2.3.2.5 is a consequence of a more general result (Proposition 2.3.2.11) which we will prove at the end of this section.

Corollary 2.3.2.6. Let $A = B = \mathcal{P}O_\infty$, where we regard $A$ as endowed with with the generalized $\infty$-operadic model structure of Remark 2.3.2.4 and $B$ as endowed with the $\infty$-operadic model structure of Proposition 2.1.4. Then the identify functor $F : A \to B$ is a left Quillen functor: that is, we can regard $\infty$-operadic model structure as a localization of the generalized $\infty$-operadic model structure (see §T.A.3.7).

Proof. Since $A$ and $B$ have the same class of cofibrations, it will suffice to show that the functor $F$ preserves weak equivalences. Let $\alpha : X \to Y$ be a map of $\infty$-preoperads. Then $\alpha$ is a weak equivalence in $A$ if and only if, for every generalized $\infty$-operad $O$, composition with $\alpha$ induces a homotopy equivalence $\text{Map}_{\mathcal{P}O_\infty}(Y, O(0)) \to \text{Map}_{\mathcal{P}O_\infty}(X, O(0))$. Since every $\infty$-operad is a generalized $\infty$-operad (Proposition 2.3.2.5), this condition implies that $\alpha$ is a weak equivalence in $B$ as well.

Notation 2.3.2.7. We let $\mathcal{O}(\infty)$ denote the underlying $\infty$-category $N(\mathcal{P}O_{\infty})$ of the simplicial model category $\mathcal{P}O_{\infty}$, with respect to the generalized $\infty$-operadic model structure of Remark 2.3.2.4. We will refer to $\mathcal{O}(\infty)$ as the $\infty$-category of generalized $\infty$-operads. It contains the $\infty$-category $\mathcal{O}_{\infty}$ of $\infty$-operads as a full subcategory.

Remark 2.3.2.8. The terminology introduced in Definition 2.3.2.2 for discussing generalized $\infty$-operads is compatible with the corresponding terminology for $\infty$-operads. For example, if $\mathcal{O}$ is an $\infty$-operad, then a morphism in $\mathcal{O}$ is inert in the sense of Definition 2.3.2.2 if and only if it is inert in the sense of Definition 2.1.2.3. If $\mathcal{O}$ and $\mathcal{O}'$ are $\infty$-operads, then a functor $f : \mathcal{O} \to \mathcal{O}'$ is a map of $\infty$-operads if and only if it is a map of generalized $\infty$-operads, and the notation $\text{Alg}_\mathcal{O}(\mathcal{O}')$ is unambiguous. Similarly, the notation of Variant 2.3.2.3 is compatible with the notion for $\infty$-operads introduced in Definition 2.1.3.1.

According to Proposition 2.3.2.5, the discrepancy between $\mathcal{O}_{\infty}$ and $\mathcal{O}(\infty)$ is controlled by the forgetful functor $F : \mathcal{O}_{\infty} \to \mathcal{O}(\infty)$, given by the formula $F(\mathcal{O}(\infty)) = \mathcal{O}(\infty)$.

Proposition 2.3.2.9. (1) For every $\infty$-category $\mathcal{C}$, the product $\mathcal{C} \times N(\mathcal{K}in_\infty)$ is a generalized $\infty$-operad.

(2) The construction $\mathcal{C} \mapsto \mathcal{C} \times N(\mathcal{K}in_\infty)$ determines a functor $G : \mathcal{K}in_\infty \to \mathcal{O}(\infty)$.

(3) The functor $G$ is a fully faithful right adjoint to the forgetful functor $F : \mathcal{O}(\infty) \to \mathcal{K}in_\infty$ described above.

Proof. Assertions (1) and (2) are obvious. We have a canonical equivalence $\nu : F \circ G \to \text{id}$ of functors from $\mathcal{K}in_\infty$ to itself. To complete the proof of (3), it will suffice to show that $\nu$ is the counit of an adjunction between $F$ and $G$. In other words, we must show that for every generalized $\infty$-operad $\mathcal{O}$ and every $\infty$-category $\mathcal{C}$, the restriction functor $\theta : \text{Alg}_\mathcal{O}(\mathcal{C}) \to \text{Fun}(\mathcal{O}(\infty), \mathcal{C})$ induces a homotopy equivalence between $\text{Alg}_\mathcal{O}(\mathcal{C})$ and the Kan complex $\text{Fun}(\mathcal{O}(\infty), \mathcal{C})$ (here we identify $\mathcal{C}$ with the underlying $\infty$-category of the generalized $\infty$-operad $\mathcal{C} \times N(\mathcal{K}in_\infty)$). In fact, we will show that $\theta$ is a trivial Kan fibration.
We observe that $\text{Alg}_O(\mathcal{C})$ can be identified with the full subcategory of $\text{Fun}(O^\otimes, \mathcal{C})$ spanned by those functors which carry each inert morphism of $O^\otimes$ to an equivalence in $\mathcal{C}$. In view of Proposition T.4.3.2.15, it will suffice to prove the following:

(a) A functor $F : O^\otimes \to \mathcal{C}$ is a right Kan extension of $F|O^\otimes_{(0)}$ if and only if $F$ carries each inert morphism in $O^\otimes$ to an equivalence in $\mathcal{C}$.

(b) Every functor $F_0 : O^\otimes_{(0)} \to \mathcal{C}$ can be extended to a functor $F : O^\otimes \to \mathcal{C}$ satisfying the equivalent conditions of (a).

To prove (a), we note that for each object $X \in O^\otimes$, the $\infty$-category $O^\otimes_{X,0} \times O^\otimes_{(0)}$ contains an initial object: namely, any inert morphism $X \to X_0$ where $X_0 \in O^\otimes_{(0)}$. Consequently, a functor $F : O^\otimes \to \mathcal{C}$ is a right Kan extension of $F|O^\otimes_{(0)}$ if and only if $F(\alpha)$ is an equivalence for every morphism $\alpha : X \to X_0$ such that $X_0 \in O^\otimes_{(0)}$. This proves the “if” direction of (a). The “only if” direction follows from the two-out-of-three property, since every inert morphism $X \to Y$ in $O^\otimes$ fits into a commutative diagram of inert morphisms

$$
\begin{array}{ccc}
X & \rightarrow & Y \\
\downarrow & & \downarrow \\
Z & \rightarrow & \\
\end{array}
$$

where $Z \in O^\otimes_{(0)}$. Assertion (b) follows immediately from Lemma T.4.3.2.13.

Our next goal is to describe the fiber of the forgetful functor $F : \text{Op}^n_{\infty} \to \text{Cat}_\infty$ over a general $\infty$-category $\mathcal{C}$.

**Definition 2.3.2.10.** Let $\mathcal{C}$ be an $\infty$-category. A $\mathcal{C}$-family of $\infty$-operads is a categorical fibration $p : O^\otimes \to \mathcal{C} \times \text{N}(\text{Fin}_*)$ with the following properties:

(a) Let $C \in \mathcal{C}$ be an object, let $X \in O^\otimes_C$ have image $\langle m \rangle \in \text{Fin}_*$, and let $\alpha : \langle m \rangle \to \langle n \rangle$ be an inert morphism. Then there exists a $p$-coCartesian morphism $\overline{\pi} : X \to Y$ in $O^\otimes_C$.

We will say that a morphism $\overline{\pi}$ of $O^\otimes$ is inert if $\pi$ is $p$-coCartesian, the image of $\overline{\pi}$ in $\text{N}(\text{Fin}_*)$ is inert, and the image of $\overline{\pi}$ in $\mathcal{C}$ is an equivalence.

(b) Let $X \in O^\otimes$ have images $C \in \mathcal{C}$ and $\langle n \rangle \in \text{N}(\text{Fin}_*)$. For $1 \leq i \leq n$, let $f_i : X \to X_i$ be an inert morphism in $O^\otimes_C$ which covers $\rho^i : \langle n \rangle \to \langle 1 \rangle$. Then the collection of morphisms $\{f_i\}_{1 \leq i \leq n}$ determines a $p$-limit diagram $(\langle n \rangle)^{p\otimes} \to O^\otimes$.

(c) For each object $C \in \mathcal{C}$, the induced map $O^\otimes_C \to \text{N}(\text{Fin}_*)$ is an $\infty$-operad.

The main result of this section is the following:

**Proposition 2.3.2.11.** Let $\mathcal{C}$ be an $\infty$-category and let $p : O^\otimes \to \mathcal{C} \times \text{N}(\text{Fin}_*)$ be a categorical fibration of simplicial sets. The following conditions are equivalent:

1. The map $p$ is a fibration of generalized $\infty$-operads, and the underlying map $O^\otimes_{(0)} \to \mathcal{C}$ is a trivial Kan fibration.

2. The map $p$ exhibits $O^\otimes$ as a $\mathcal{C}$-family of $\infty$-operads.

**Remark 2.3.2.12.** In the special case $\mathcal{C} = \Delta^0$, the definition of a $\mathcal{C}$-operad family reduces to the usual definition of an $\infty$-operad. Consequently, Proposition 2.3.2.11 implies Proposition 2.3.2.5 (by taking $\mathcal{C} = \Delta^0$).

**Corollary 2.3.2.13.** Let $\mathcal{C}$ be an $\infty$-category. Then the fiber product $\text{Op}^n_{\infty} \times \text{Cat}_\infty \{\mathcal{C}\}$ can be identified with the full subcategory of $(\text{Op}^n_{\infty})/\mathcal{C} \times \text{N}(\text{Fin}_*)$ spanned by those maps $O^\otimes \to \mathcal{C} \times \text{N}(\text{Fin}_*)$ which exhibit $O^\otimes$ as a $\mathcal{C}$-family of $\infty$-operads.
In other words, we can think of a generalized ∞-operad as consisting of a pair \((\mathcal{C}, O^\bigcirc)\), where \(\mathcal{C}\) is an ∞-category and \(O^\bigcirc\) is a \(\mathcal{C}\)-family of ∞-operads.

**Proof of Corollary 2.3.2.13.** We can identify the fiber product \(\text{Op}_{\infty}^n \times \text{cat}_{\sim} \{\mathcal{C}\}\) with the full subcategory of \(\text{Op}_{\infty}^n \times \text{cat}_{\sim} (\text{Cat}_{\infty})/e\) spanned by those pairs \((O^\bigcirc, \alpha : O^\bigcirc_0 \to \mathcal{C})\) where \(O^\bigcirc\) is a generalized ∞-operad and \(\alpha\) is an equivalence of ∞-categories. Using Proposition 2.3.2.9, we can identify this fiber product with the \(\mathcal{C}\)-category \(\text{cat}_{\sim} \{\mathcal{C}\}\) spanned by those maps of generalized ∞-operads \(O^\bigcirc : \mathcal{C} \times N(\text{Fin}_*)\) which induce a categorical equivalence \(O^\bigcirc_0 \to \mathcal{C}\). This subcategory evidently contains all \(\mathcal{C}\)-families of ∞-operads. Conversely, if \(f : O^\bigcirc \to \mathcal{C} \times N(\text{Fin}_*)\) is an arbitrary map of generalized ∞-operads which induces a categorical equivalence \(O^\bigcirc_0 \to \mathcal{C}\), then we can factor \(f\) as a composition

\[
O^\bigcirc \xrightarrow{f'} O^\bigcirc \xrightarrow{f''} \mathcal{C} \times N(\text{Fin}_*),
\]

where \(f'\) is an equivalence of generalized ∞-operads and \(f''\) is a categorical fibration. It follows that \(f''\) induces a trivial Kan fibration \(O^\bigcirc_0 \to \mathcal{C}\) and therefore exhibits \(O^\bigcirc\) as a \(\mathcal{C}\)-family of ∞-operads. \(\square\)

We conclude this section by proving Proposition 2.3.2.11.

**Proof of Proposition 2.3.2.11.** We first prove that \((1) \Rightarrow (2)\). Assume that \(p : O^\bigcirc \to \mathcal{C} \times N(\text{Fin}_*)\) is a fibration of generalized ∞-operads. Then \(O^\bigcirc\) is a generalized ∞-operad and \(p\) is a categorical fibration which carries inert morphisms in \(O^\bigcirc\) to equivalences in \(\mathcal{C}\). We will show that \(p\) satisfies conditions \((a), (b),\) and \((c)\) of Definition 2.3.2.10. To prove \((a)\), suppose that \(X \in O^\bigcirc\) lies over \((C, \langle m \rangle) \in \mathcal{C} \times N(\text{Fin}_*)\) and that we are given an inert morphism \(\alpha : \langle m \rangle \to \langle n \rangle\) in \(N(\text{Fin}_*)\). Since \(O^\bigcirc\) is a generalized ∞-operad, we can lift \(\alpha\) to an inert \(\pi : X \to X'\) in \(O^\bigcirc\), lying over a map \((C, \langle m \rangle) \to (C, \langle n \rangle)\). Because \(p\) preserves inert morphisms, the underlying map \(C \to C'\) is an equivalence. Choosing a homotopy inverse, we get an equivalence \((C', \langle n \rangle) \to (C, \langle n \rangle)\) in \(\mathcal{C} \times N(\text{Fin}_*)\) which (since \(p\) is a categorical fibration) can be lifted to an equivalence \(\beta : X' \to \hat{X}'\) in \(O^\bigcirc\). Since \(p\) has the right lifting property with respect to the horn inclusion \(\Lambda^2_1 \subseteq \Delta^2\), we can choose a composition \(\gamma \simeq \beta \circ \pi\) lying over the morphism \((\text{id}_C, \alpha) : (C, \langle m \rangle) \to (C, \langle n \rangle)\). We claim that \(\gamma\) is \(p\)-coCartesian. Since \(\gamma\) is equivalent to \(\pi\), it suffices to show that \(\alpha\) is \(p\)-coCartesian. This follows from Proposition T.2.4.1.3, since \(\alpha\) is inert and \(p(\alpha)\) is coCartesian with respect to the projection \(\pi : \mathcal{C} \times N(\text{Fin}_*) \to N(\text{Fin}_*)\).

We now prove \((b)\). Suppose we are given an object \(X \in O^\bigcirc_{C, \langle n \rangle}\) together with inert morphisms \(X \to X_i\) in \(O^\bigcirc\) covering the maps \(p' : \langle n \rangle \to \langle 1 \rangle\). We wish to show that the induced map \(q : \langle n \rangle^{\text{op}} \to O^\bigcirc\) is a \(p\)-limit diagram. The proof proceeds by induction on \(n\).

If \(n = 0\), then we must show that every object \(X \in O^\bigcirc_{C, \langle 0 \rangle}\) is \(p\)-final. In other words, we must show that for every object \(Y \in O^\bigcirc_{D, \langle m \rangle}\), the homotopy fiber of the map

\[
\text{Map}_{O^\bigcirc}(Y, X) \to \text{Map}_{\mathcal{C} \times N(\text{Fin}_*)}((D, \langle m \rangle), (C, \langle 0 \rangle))
\]

is contractible: that is, \(\text{Map}_{O^\bigcirc}(Y, X) \to \text{Map}_{\mathcal{C}}(D, C)\) is a homotopy equivalence. To prove this, we choose an inert morphism \(\alpha : Y \to Y'\) covering the unique map \(\langle m \rangle \to \langle 0 \rangle\) in \(\text{Fin}_*\). Since the image of \(\alpha\) in \(\mathcal{C}\) is an equivalence, we are free to replace \(Y\) by \(Y'\) and to thereby assume that \(m = 0\). In this case, the desired assertion follows from the assumption that \(O^\bigcirc_0 \to \mathcal{C}\) is a trivial Kan fibration. If \(n = 1\), there is nothing to prove. Assume that \(n > 1\). Let \(\beta : \langle n \rangle \to \langle n - 1 \rangle\) be defined by the formula

\[
\beta(i) = \begin{cases} 
  i & \text{if } 1 \leq i \leq n - 1 \\
  * & \text{otherwise}, 
\end{cases}
\]

and choose a \(p\)-coCartesian morphism \(g : X \to X'\) lying over \((\text{id}_C, \beta)\). Using the assumption that \(g\) is \(p\)-coCartesian, we obtain factorizations of \(f_i\) as a composition

\[
X \xrightarrow{g} X' \xrightarrow{f'_i} X_i
\]
for $1 \leq i \leq n$. These factorizations determine a diagram

$$q' : ((n-1)^\otimes \coprod \{n\})^\otimes \to \cO_C^\otimes$$

extending $q$. Fix an object $X_0 \in \cO_C^\otimes(0)$. We have seen that $X_0$ is a $p$-final object of $\cC^\otimes$. Since $(0)$ is also a final object of $N(\text{Fin}_*)$, we deduce that $X_0$ is a final object of $\cO_C^\otimes$. We may therefore extend $q'$ to a diagram

$$q'' : \{x\} \to ((n-1)^\otimes \coprod \{n\}) \to \{x_0\} \to \cO_C^\otimes$$

carrying $x$ to $X$ and $x_0$ to $X_0$.

In view of Lemma T.4.3.2.7, to prove that $q$ is a $p$-limit diagram it will suffice to show the following:

(i) The restriction $q''|(n-1)^\otimes \coprod \{n\} \to \{x_0\}$ is a $p$-right Kan extension of $q''|\{n\}$.

(ii) The diagram $q''$ is a $p$-limit.

Using Proposition T.4.3.2.8, we can break the proof of (a) into two parts:

(i') The restriction $q''|(n-1)^\otimes \coprod \{n\} \to \{x_0\}$ is a $p$-right Kan extension of $q''|(n-1)^\otimes \coprod \{n\}$.

(ii') The restriction $q''|(n-1)^\otimes \coprod \{n\}$ is a $p$-right Kan extension of $q''|\{n\}$.

Assertion (i') follows from the observation that $X_0$ is a $p$-final object of $\cC^\otimes$, and (i'') follows from the inductive hypothesis.

To prove (ii), we observe that the inclusion $(\emptyset^\otimes \coprod \{n\}) \to ((n-1)^\otimes \coprod \{n\}) \to \{x_0\}$ is left cofinal (for example, using Theorem T.4.1.3.1). Consequently, it suffices to show that the restriction of $q'' = q|(\{x\} \to \emptyset^\otimes \coprod \{n\} \to \{x_0\})$ is a $p$-limit diagram. Since $p \circ q''$ is coCartesian (the projection of $p \circ q''$ to $\cC$ is constant, and therefore a pullback square in $\cC$), it will suffice to show that $q''$ is a $p \circ p$-limit diagram (Proposition T.2.4.1.3). This follows from our assumption that $\cO^\otimes$ is a generalized $\infty$-operad, since $q''$ is a $p$-coCartesian lift of the inert diagram

$$\xymatrix{ (n) \ar[r]^-{\rho} \ar[d]^-{\beta} & (1) \ar[d] \ar[r]^-{\beta} & (n-1) \ar[r] & (0). }$$

We next verify (c): that is, for $n \geq 0$ and every object $C \in \cC$, the maps

$$\rho : \cO_{(C,(n))}^\otimes \to \cO_{(C,(1))}^\otimes$$

induce an equivalence of $\infty$-categories $\theta_n : \cO_{(C,(n))}^\otimes \to \left(\cO_{(C,(1))}^\otimes\right)^n$. The proof again proceeds by induction on $n$. When $n = 0$, this follows from our assumption that $\cO^\otimes_0 \to \cC$ is a trivial Kan fibration (and therefore has contractible fibers). When $n = 1$ there is nothing to prove. Assume therefore that $n \geq 2$ and observe that $\theta_n$ is equivalent to the composition

$$\xymatrix{ \cO_{(C,(n))}^\otimes \ar[r]^-{\beta \times \alpha} & \cO_{(C,(n-1))}^\otimes \times \cO_{(C,(1))}^\otimes \ar[r]^-{\theta_{n-1} \times \text{id}} & \left(\cO_{(C,(1))}^\otimes\right)^n, }$$

where $\beta : (n) \to (n-1)$ is defined as above and $\alpha = \rho^n$. By virtue of the inductive hypothesis, it suffices to show that the map $\beta \times \alpha$ is an equivalence of $\infty$-categories. We have a homotopy coherent diagram of $\infty$-categories

$$\xymatrix{ \cO_{(C,(n))}^\otimes \ar[r]^-{\beta} \ar[d]^-{\alpha} & \cO_{(C,(n-1))}^\otimes \ar[d] \ar[r]^-{\alpha} & \cO_{(C,(1))}^\otimes \ar[d] \ar[r]^-{\beta} & \cO_{(C,(0))}^\otimes. }$$
Because $O^\otimes_C \simeq O^\otimes \times e \times N(\mathcal{F}_{\text{Fin}_*})\{\{C\}\times N(\mathcal{F}_{\text{Fin}_*})$ is a generalized $\infty$-operad, this square is a homotopy pullback. Since $O^\otimes_{\langle C,\{0\}\rangle}$ is a contractible Kan complex, we conclude that $\beta \times \alpha$ is a categorical equivalence as desired. This completes the proof that $(1) \Rightarrow (2)$.

We now prove that $(2) \Rightarrow (1)$. Assume that $p$ exhibits $O^\otimes$ as a $\mathcal{C}$-family of $\infty$-operads. We wish to show that $O^\otimes$ is a generalized $\infty$-operad and that $p$ carries inert morphisms in $O^\otimes$ to equivalences in $\mathcal{C}$. Suppose first that we are given an object $X \in O^\otimes_C$ lying over $(m) \in N(\mathcal{F}_{\text{Fin}_*})$ and an inert morphism $\alpha : (m) \to (n)$ in $\mathcal{F}_{\text{Fin}_*}$. We wish to prove that $\alpha$ can be lifted to a $(\varphi \circ p)$-coCartesian morphism $\overline{\alpha}$ in $O^\otimes$ such that $p(\overline{\alpha})$ induces an equivalence in $\mathcal{C}$. In view of Proposition T.2.4.1.3, it will suffice to show that the morphism $(id_C, \alpha) \in \mathcal{C} \times N(\mathcal{F}_{\text{Fin}_*})$ can be lifted to a $p$-coCartesian morphism in $O^\otimes$, which follows from assumption $(a)$ of Definition 2.3.2.10.

To complete the proof that $O^\otimes$ is a generalized $\infty$-operad, we fix a diagram $\sigma : \Delta^1 \times \Delta^1 \to N(\mathcal{F}_{\text{Fin}_*})$ of inert morphisms

$$\begin{array}{ccc}
\langle n \rangle & \xrightarrow{\alpha} & \langle m \rangle \\
\beta \downarrow & & \downarrow \gamma \\
\langle m' \rangle & \xrightarrow{\beta} & \langle k \rangle
\end{array}$$

which induces a bijection $\langle m \rangle^\circ \coprod_{\langle k \rangle^\circ} \langle m' \rangle^\circ$. We wish to prove the following:

(iii) Every map $\overline{\sigma} : \Delta^1 \times \Delta^1 \to O^\otimes$ lifting $\sigma$ which carries every morphism in $\Delta^1 \times \Delta^1$ to an inert morphism in $O^\otimes$ is a $(\varphi \circ p)$-limit diagram (since $p$ carries inert morphisms to equivalences in $\mathcal{C}$ and the simplicial set $\Delta^1 \times \Delta^1$ is weakly contractible, we know automatically that $p(\overline{\sigma})$ is a $\pi$-limit diagram; by virtue of Proposition T.2.4.1.3, it suffices to show that $\overline{\sigma}$ is a $p$-limit diagram).

(iv) Let $\sigma_0$ denote the restriction of $\sigma$ to the full subcategory $K$ of $\Delta^1 \times \Delta^1$ obtained by omitting the initial object. If $\sigma_0 : K \to O^\otimes$ is a map lifting $\sigma_0$ which carries every edge of $K$ to an inert morphism in $O^\otimes$, then $\overline{\sigma}_0$ can be extended to a map $\overline{\sigma} : \Delta^1 \times \Delta^1 \to O^\otimes$ satisfying the hypothesis of $(i)$.

To prove these claims, consider the $\infty$-category $\mathcal{A} = (\Delta^1 \times \Delta^1) \times \langle 0 \rangle^\circ$, and let $A$ denote the subcategory obtained by removing those morphisms of the form $(1,1) \to i$ where $i \in \gamma^{-1}\{\ast\}$, $(0,1) \to i$ where $i \in \beta^{-1}\{\ast\}$, and $(1,0) \to i$ where $i \in \alpha^{-1}\{\ast\}$. We observe that $\sigma$ can be extended uniquely to a diagram $\tau : A \to N(\mathcal{F}_{\text{Fin}_*})$ such that $\tau(i) = \langle 1 \rangle$ for $i \in \langle 0 \rangle^\circ$, and $\tau$ carries the morphism $(0,0) \to i$ to the map $\rho^1 : (n) \to \langle 1 \rangle$. The assumption that $\langle m \rangle^\circ \simeq \langle n \rangle^\circ \coprod_{\langle k \rangle^\circ} \langle m' \rangle^\circ$ guarantees that for each $i \in \langle n \rangle^\circ$, the $\infty$-category $(\Delta^1 \times \Delta^1) \times_A A/i$ contains a final object corresponding to a morphism $(j,j') \to i$ in $A$, where $(j,j') \neq (0,0)$. Note that the image of this morphism in $N(\mathcal{F}_{\text{Fin}_*})$ is inert.

Let $\overline{\tau} : \Delta^1 \times \Delta^1$ be as $(iii)$. We may assume without loss of generality that the composition $\Delta^1 \times \Delta^1 \to O^\otimes \xrightarrow{\rho^0} \mathcal{C} \times N(\mathcal{F}_{\text{Fin}_*}) \xrightarrow{e} \mathcal{C}$ is the constant functor taking some value $C \in \mathcal{C}$. Using Lemma T.4.3.2.13, we can choose a $p$-left Kan extension $\tau : A \to O^\otimes_C$ of $\overline{\tau}$ such that $p \circ \tau = \tau$. Let $A^0$ denote the full subcategory of $A$ obtained by removing the object $(0,0)$. We observe that the inclusion $K \subseteq A^0$ is right cofinal (Theorem T.4.1.3.1). Consequently, to prove that $\tau$ is a $p$-limit diagram, it suffices to show that $\tau$ is a $p$-limit diagram. Since $O^\otimes$ is a $\mathcal{C}$-family of $\infty$-operads, the restriction of $\tau$ to $(\{0,0\}) \times \langle n \rangle^\circ$ is a $p$-limit diagram. To complete the proof, it will suffice (by virtue of Lemma T.4.3.2.7) to show that $\tau|A^0$ is a $p$-right Kan extension of $\tau|\langle n \rangle^\circ$. This again follows immediately from our assumption that $O^\otimes$ is a $\mathcal{C}$-family of $\infty$-operads.

We now prove $(iv)$. Let $\sigma_0 : K \to O^\otimes$ be as in $(iv)$; we may again assume without loss of generality that this diagram factors through $O^\otimes_C$ for some $C \in \mathcal{C}$. Using Lemma T.4.3.2.13, we can choose a $p$-left Kan extension $\tau_0 : A^0 \to O^\otimes_C$ of $\sigma_0$ covering the map $\tau_0 = \tau|A^0$. Using the assumption that $O^\otimes_C$ is an $\infty$-operads, we deduce that $\tau_0$ is a $p$-right Kan extension of $\tau_0|\langle n \rangle^\circ$, and that $\tau_0|\langle n \rangle^\circ$ can be extended to a $p$-limit diagram $\tau_0 : (\{0,0\}) \times \langle n \rangle^\circ \to O^\otimes_C$ lifting $\tau|((\{0,0\}) \times (\langle n \rangle^\circ))$; moreover, any such diagram carries each edge of $\{0,0\} \times \langle n \rangle^\circ$ to an inert morphism in $O^\otimes_C$. Invoking Lemma T.4.3.2.7, we can amalgamate $\tau_0$ and $\sigma_0$ to obtain a diagram $\overline{\tau} : A \to O^\otimes_C$ covering $\tau$. We claim that $\overline{\tau} = \tau|\Delta^1 \times \Delta^1$ is the desired extension of $\sigma_0$. To
prove this, it suffices to show that \( \tau \) carries each morphism of \( \Delta^1 \times \Delta^1 \) to an inert morphism of \( O^\otimes \). Since the composition of inert morphisms in \( O^\otimes \) is inert, it will suffice to show that the maps

\[
\tau(0, 1) \xrightarrow{\overline{\alpha}} \tau(0, 0) \xrightarrow{\overline{\beta}} \tau(1, 0)
\]

are inert, where \( \overline{\alpha} \) and \( \overline{\beta} \) are the morphisms lying over \( \alpha \) and \( \beta \) determined by \( \tau \). We will prove that \( \overline{\alpha} \) is inert; the case of \( \overline{\beta} \) follows by the same argument. We can factor \( \overline{\alpha} \) as a composition

\[
\tau(0, 0) \xrightarrow{\alpha} \tau(0, 0) \xrightarrow{\alpha'} \tau(1, 0).
\]

We wish to prove that \( \alpha'' \) is an equivalence in the \( \infty \)-category \( O^\otimes_{(C,(m))} \). Since \( O^\otimes_C \) is an \( \infty \)-operad, it will suffice to show that for \( 1 \leq j \leq m \), the functor \( \rho^j : O^\otimes_{(C,(m))} \to O_C \) carries \( \alpha'' \) to an equivalence in \( O_C \).

Unwinding the definitions, this is equivalent to the requirement that the map \( \tau(0, 0) \to \tau(i) \) is inert, where \( i = \alpha^{-1}(j) \in (n)^\circ \), which follows immediately from our construction. \( \Box \)

### 2.3.3 Approximations to \( \infty \)-Operads

In §2.3.2, we introduced the notion of a generalised \( \infty \)-operad. We can regard the \( \infty \)-category \( Op_{\infty} \) of \( \infty \)-operads as a full subcategory of the \( \infty \)-category \( Op_{\infty}^n \) of generalised \( \infty \)-operads. We now observe that the inclusion \( Op_{\infty} \hookrightarrow Op_{\infty}^n \) admits a left adjoint.

**Definition 2.3.3.1.** Let \( O^\otimes \) be a generalised \( \infty \)-operad and \( O'^\otimes \) an \( \infty \)-operad. We will say that a map \( \gamma : O^\otimes \to O'^\otimes \) of generalised \( \infty \)-operads assembles \( O^\otimes \) to \( O'^\otimes \) if, for every \( \infty \)-operad \( O'^{\otimes} \), composition with \( \gamma \) induces an equivalence of \( \infty \)-categories \( \text{Alg}_O'(O'^n) \to \text{Alg}_O'(O'^n) \). In this case we will also say that \( O'^\otimes \) is an assembly of \( O^\otimes \), or that \( \gamma \) exhibits \( O'^\otimes \) as an assembly of \( O^\otimes \).

**Remark 2.3.3.2.** A map of generalised \( \infty \)-operads \( \gamma : O^\otimes \to O'^\otimes \) assembles \( O^\otimes \) to \( O'^\otimes \) if and only if it exhibits \( O'^\otimes \) as an \( \text{Op}_{\infty} \)-localization of \( O^\otimes \in \text{Op}_{\infty}^n \). In other words, \( \gamma \) assembles \( O^\otimes \) to \( O'^\otimes \) if and only if \( O'^\otimes \) is an \( \infty \)-operad, and for every \( \infty \)-operad \( O'^{\otimes} \), composition with \( \gamma \) induces a homotopy equivalence \( \theta(O'^{\otimes}) : \text{Map}_{\text{Op}_{\infty}^n}(O'^\otimes, O'^{\otimes}) \to \text{Map}_{\text{Op}_{\infty}^n}(O^\otimes, O'^{\otimes}) \). The “only if” direction is clear, since the mapping spaces \( \text{Map}_{\text{Op}_{\infty}^n}(O'^\otimes, O'^{\otimes}) \) and \( \text{Map}_{\text{Op}_{\infty}^n}(O^\otimes, O'^{\otimes}) \) can be identified with the Kan complexes \( \text{Alg}_O'(O'^{\otimes}) \) and \( \text{Alg}_O(O'^{\otimes}) \). Conversely, suppose that \( \theta(O'^{\otimes}) \) is a homotopy equivalence for every \( \infty \)-operad \( O'^{\otimes} \); we wish to show that each of the maps \( \text{Alg}_O'(O'^n) \to \text{Alg}_O(O'^n) \) is a categorical equivalence. It suffices to show that for every simplicial set \( K \), the map \( \text{Fun}(K, \text{Alg}_O'(O'^n)) \to \text{Fun}(K, \text{Alg}_O(O'^n)) \) induces a homotopy equivalence on the underlying Kan complexes; this map can be identified with \( \theta(\mathcal{C}) \), where \( \mathcal{C} \) is the \( \infty \)-operad \( \text{Fun}(K, O'^{\otimes}) \times_{\text{Fun}(K, O^{\otimes})} \text{N}(\text{Fin}_n) \).

**Remark 2.3.3.3.** Since the \( \infty \)-category \( Op_{\infty} \) is a localization of the \( \infty \)-category \( Op_{\infty}^n \) (Corollary 2.3.2.6), we conclude that for every generalised \( \infty \)-operad \( O^\otimes \) there exists an assembly map \( \gamma : O^\otimes \to O'^\otimes \), which is uniquely determined up to equivalence. The process of assembly determines a functor \( \text{Assem} : \text{Op}_{\infty}^n \to \text{Op}_{\infty} \), which is left adjoint to the inclusion \( \text{Op}_{\infty} \leq \text{Op}_{\infty}^n \). This functor can be described concretely as follows: for every generalised \( \infty \)-operad \( O^\otimes \), we can identify \( \text{Assem}(O^\otimes) \) with an \( \infty \)-operad \( O'^\otimes \), where \( O'^{\otimes} \) as a fibrant replacement for the \( \infty \)-preoperad \( O^\otimes \) with respect to the \( \infty \)-operadic model structure on \( \mathcal{P} \text{Op}_{\infty} \).

**Remark 2.3.3.4.** In the situation of Definition 2.3.3.1, suppose that \( O^\otimes \to C \times \text{N}(\text{Fin}_n) \) is a \( C \)-family of \( \infty \)-operads. We can think of an object of \( \text{Alg}_O(O'^n) \) as a family of \( \infty \)-operad maps \( O^\otimes_C \to O'^{\otimes} \) parametrised by the objects \( C \in C \in \text{C} \). The map \( \gamma \) assembles \( O^\otimes \) if this is equivalent to the data of a single \( \infty \)-operad map \( O^\otimes \to O'^{\otimes} \). In this case, we can view \( O'^\otimes \) as a sort of colimit of the family of \( \infty \)-operads \( \{O^\otimes_C\}_{C \in C} \). This description is literally correct in the case where \( C \in C \) is a Kan complex.

Our goal in §2.3.4 is to analyze the relationship between a generalised \( \infty \)-operad \( O^\otimes \) and its assembly \( \text{Assem}(O^\otimes) \) (under some mild hypotheses in \( O \)). To carry out this analysis, we need a criterion for detecting
2.3. DISINTEGRATION AND ASSEMBLY

weak equivalences in the model category $\mathcal{P}$Op$_{\infty}$ of $\infty$-preoperads. Our goal in this section is to establish such a criterion, whose formulation involves the notion of a (weak) approximation to an $\infty$-operad, which will have many other applications in later chapters of this book.

**Warning 2.3.3.5.** The remaining material in this section is of a rather technical nature. We recommend that the casual reader skip it for the time being, referring back to it as necessary.

**Definition 2.3.3.6.** Let $p: \mathcal{O} \to N(\mathcal{F}_{\text{fin}})$ be an $\infty$-operad. We will say that a categorical fibration $f: \mathcal{E} \to \mathcal{O}$ is an approximation to $\mathcal{O}$ if it satisfies the following conditions:

(1) Let $p' = p \circ f$, let $C \in \mathcal{E}$ be an object, and let $(n) = p'(C)$. For $1 \leq i \leq n$, there exists a locally $p'$-coCartesian morphism $\alpha_i: C \to C_i$ in $\mathcal{E}$ covering the map $p'(n) \to \{1\}$. Moreover, $f(\alpha_i)$ is an inert morphism in $\mathcal{O}$.

(2) Let $C \in \mathcal{E}$ and let $\alpha: X \to f(C)$ be an active morphism in $\mathcal{O}$. Then there exists an $f$-Cartesian morphism $\pi: X \to C$ lifting $\alpha$.

We will say that a categorical fibration $f: \mathcal{E} \to \mathcal{O}$ is a weak approximation to $\mathcal{O}$ if it satisfies condition (1) together with the following:

(2') Let $C \in \mathcal{E}$ and let $\alpha: X \to f(C)$ be an arbitrary morphism in $\mathcal{O}$. Let $\mathcal{E} \subseteq \mathcal{E}/C \times_{\mathcal{O}/f(C)} \mathcal{O}/f(C)$ be the full subcategory spanned by those objects corresponding to pairs $(\beta: C' \to C, \gamma: X \to f(C'))$ such that $\gamma$ is inert. Then the $\infty$-category $\mathcal{E}$ is weakly contractible.

If $f: \mathcal{E} \to \mathcal{O}$ is an arbitrary map of $\infty$-categories, we will say that $f$ is a (weak) approximation if it factors as a composition $\mathcal{E} \xrightarrow{f'} \mathcal{E}' \xrightarrow{f''} \mathcal{O}$, where $f'$ is a categorical equivalence and $f''$ is a categorical fibration which is a (weak) approximation to $\mathcal{O}$.

**Remark 2.3.3.7.** In the situation of Definition 2.3.3.6, the condition that $f: \mathcal{E} \to \mathcal{O}$ is a (weak) approximation does not depend on the choice of factorization $\mathcal{E} \xrightarrow{f'} \mathcal{E}' \xrightarrow{f''} \mathcal{O}$, provided that $f'$ is a categorical equivalence and $f''$ is a categorical fibration.

**Remark 2.3.3.8.** Let $\mathcal{O}$ be an $\infty$-operad and let $f: \mathcal{E} \to \mathcal{O}$ be a categorical fibration which is an approximation to $\mathcal{O}$. We will say that a morphism $\alpha$ in $\mathcal{E}$ is $f$-active if $\alpha$ is $f$-Cartesian and $f(\alpha)$ is an active morphism in $\mathcal{O}$. We will say that $\alpha$ is $f$-inert if $f(\alpha)$ is an inert morphism in $\mathcal{O}$. It follows from Proposition 2.1.2.5 that $\mathcal{E}$ admits a factorization system $(S_L, S_R)$, where $S_L$ is the collection of $f$-inert morphisms in $\mathcal{E}$ and $S_R$ is the collection of $f$-active morphisms in $\mathcal{E}$.

**Remark 2.3.3.9.** Let $\mathcal{O}$ be an $\infty$-operad and let $f: \mathcal{E} \to \mathcal{O}$ be an approximation to $\mathcal{O}$. If $u: \mathcal{O}/\mathcal{O} \to \mathcal{O}$ is a fibration of $\infty$-operads, then the induced map $\mathcal{E} \times_{\mathcal{O}/\mathcal{O}} \mathcal{O}/\mathcal{O} \to \mathcal{O}/\mathcal{O}$ is an approximation to $\mathcal{O}$. Indeed, the assumption that $u$ is a fibration of $\infty$-operads guarantees that the fiber product $\mathcal{E} \times_{\mathcal{O}/\mathcal{O}} \mathcal{O}/\mathcal{O}$ is also a homotopy fiber product. We may therefore replace $\mathcal{E}$ by an equivalent $\infty$-category and thereby reduce to the case where $f$ is a categorical fibration, in which case the result follows readily from Definition 2.3.3.6.

**Lemma 2.3.3.10.** Let $\mathcal{O}$ be an $\infty$-operad and let $f: \mathcal{E} \to \mathcal{O}$ be an approximation to $\mathcal{O}$. Then $f$ is a weak approximation to $\mathcal{O}$.

**Proof.** Fix an object $C \in \mathcal{E}$ and a morphism $\alpha: X \to f(C)$, and let $\mathcal{E}' \subseteq \mathcal{E}/C \times_{\mathcal{O}/f(C)} \mathcal{O}/f(C)$ be as in Definition 2.3.3.6. The map $\alpha$ fits into a commutative diagram $\sigma$:

$$
\begin{array}{ccc}
X' & \xrightarrow{\alpha'} & X \\
\downarrow & & \downarrow \alpha \\
X & \xrightarrow{\alpha''} & f(C),
\end{array}
$$

where $\alpha'$ is inert and $\alpha''$ is active. Since $f$ is an approximation to $\mathcal{O}$, we can lift $\alpha''$ to an $f$-Cartesian morphism $\pi'': C' \to C$. The pair $(\pi'', \sigma)$ is a final object of $\mathcal{E}'$, so that $\mathcal{E}'$ is weakly contractible. \qed
We will be primarily interested in the case where \( f: C^\otimes \to \mathcal{O}^\otimes \) is a map of generalized \( \infty \)-operads. In this case, the condition that \( f \) be a weak approximation is much easier to formulate:

**Proposition 2.3.3.11.** Let \( p: \mathcal{O}^\otimes \to N(\mathcal{F}_{\text{Fin}_*}) \) be an \( \infty \)-operad, and let \( f: C \to \mathcal{O}^\otimes \) be a categorical fibration. Assume that \( C \) satisfies the following condition:

\( (*) \) For every object \( C \in C \) and every inert morphism \( \beta: (p \circ f)(C) \to \langle n \rangle \) in \( N(\mathcal{F}_{\text{Fin}_*}) \), there exists an \((p \circ f)\)-coCartesian morphism \( \overline{\beta}: C \to C' \) in \( C \) lifting \( \beta \), and the image \( f(\overline{\beta}) \) is an inert morphism in \( \mathcal{O}^\otimes \).

Then \( f \) is a weak approximation if and only if the following condition is satisfied:

\( (\ast') \) For every object \( C \in C \) and every active morphism \( \alpha: X \to f(C) \) in \( \mathcal{O}^\otimes \), the \( \infty \)-category

\[
\mathcal{E}_{/C} \times_{\mathcal{O}^\otimes_{/f(C)}} \{X\}
\]

is weakly contractible.

**Remark 2.3.3.12.** Condition \( (*) \) of Proposition 2.3.3.11 is automatically satisfied if \( f \) is a fibration of generalized \( \infty \)-operads.

**Proof.** It is obvious that condition \((1)\) of Definition 2.3.3.6 satisfies \( (*) \). It will therefore suffice to show that if \((*)\) is satisfied, then condition \((2')\) of Definition 2.3.3.6 is equivalent to \((\ast')\). We first show that \((2') \Rightarrow (\ast')\).

Consider an arbitrary morphism \( \alpha: X \to f(C) \) in \( \mathcal{O}^\otimes \) and let \( \mathcal{E} \) be defined as in \((2')\). Let \( \mathcal{E}_0 \) be the full subcategory of \( \mathcal{E} \) spanned by those objects which correspond to factorizations

\[
X \xrightarrow{\beta} f(D) \xrightarrow{f(\gamma)} f(C)
\]

of \( \alpha \), where \( \beta \) is an inert morphism in \( \mathcal{O}^\otimes \) and \( f(\gamma) \) is an active morphism in \( \mathcal{O}^\otimes \). Using \((*)\), we conclude that the inclusion \( \mathcal{E}_0 \subseteq \mathcal{E} \) admits a left adjoint and is therefore a weak homotopy equivalence. Let \( \mathcal{X} \) be the full subcategory of \( \mathcal{O}^\otimes_{X/\!f(C)} \) spanned by those diagrams

\[
X \xrightarrow{\alpha'} X' \xrightarrow{\alpha''} f(C)
\]

such that \( \alpha'' \) is inert and \( \alpha'' \) is active, so that \( \mathcal{X} \) is a contractible Kan complex. Then \( \mathcal{E}_0 \) can be identified with the fiber product \( \mathcal{O}^\otimes_{/f(C)} \times_{\mathcal{O}^\otimes_{/f(C)}} X \), and is therefore categorically equivalent to the fiber \( \mathcal{O}^\otimes_{/f(C)} \times_{\mathcal{O}^\otimes_{/f(C)}} \{X'\} \) for any object \( X' \in \mathcal{E} \). If \((\ast')\) is satisfied, then this fiber product is weakly contractible and \((2')\) follows. Conversely, assume that \((2')\) is satisfied. If \( \alpha: X \to f(C) \) is active, then we take \( X' = X \) to conclude that \( \mathcal{O}^\otimes_{/f(C)} \times_{\mathcal{O}^\otimes_{/f(C)}} \{X\} \cong \mathcal{E}_0 \) is weakly contractible, which proves \((\ast')\). \( \square \)

To state our next result, we need a bit of notation. For each integer \( n \geq 0 \), we let \( \text{Tup}_n \) denote the subcategory of \( N(\mathcal{F}_{\text{Fin}_*})_{/\langle n \rangle} \) whose objects are active morphisms \( \langle m \rangle \to \langle n \rangle \) in \( N(\mathcal{F}_{\text{Fin}_*}) \), and whose morphisms are commutative diagrams

\[
\begin{array}{ccc}
\langle m \rangle & \xrightarrow{\alpha} & \langle m \rangle \\
\downarrow & & \downarrow \\
\langle n \rangle & & \\
\end{array}
\]

where \( \alpha \) is a bijection of pointed finite sets. The \( \infty \)-category \( \text{Tup}_n \) is equivalent to the nerve of the groupoid of \( n \)-tuples of finite sets.
Lemma 2.3.3.13. Let $X$ be a Kan complex and let $\theta : y \to X$ be a categorical fibration. Then, for every vertex $X \in X$, the pullback diagram

$$
\begin{array}{ccc}
Y_X & \to & Y \\
\downarrow & & \downarrow \theta \\
\{X\} & \to & X
\end{array}
$$

is a homotopy pullback diagram (with respect to the usual model structure on $\mathbf{Set}_\Delta$).

Proof. Choose a factorization of the inclusion $i : \{X\} \to X$ as a composition

$$\{X\} \xrightarrow{i'} \overline{X} \xrightarrow{i''} X,$$

where $i''$ is a Kan fibration and $\overline{X}$ is a contractible Kan complex, so we have a commutative diagram

$$
\begin{array}{ccc}
Y_X & \to & Y \\
\downarrow & & \downarrow \theta \\
\{X\} & \to & \overline{X} \hookrightarrow X.
\end{array}
$$

Since $i''$ is a Kan fibration, the right square is a homotopy pullback diagram with respect to the usual model structure (since the usual model structure is right-proper). To prove that the outer square is a homotopy pullback diagram, it will suffice to show that $i'$ and $j'$ are weak homotopy equivalences. We will complete the proof by showing that $j'$ is a categorical equivalence. Since $\theta$ is a categorical fibration and the simplicial sets $\{X\}, \overline{X},$ and $X$ are $\infty$-categories, the left square is a homotopy pullback diagram with respect to the Joyal model structure. It will therefore suffice to show that $i'$ is a categorical equivalence, which is obvious. □

Proposition 2.3.3.14. Let $p : \mathcal{O}^\otimes \to \mathbf{N}(\mathbf{Fin}_*)$ be an $\infty$-operad and let $f : \mathcal{C} \to \mathcal{O}^\otimes$ be a functor. Assume that $f$ satisfies condition $(\ast)$ of Proposition 2.3.3.11 and that the $\infty$-category $\mathcal{O}$ is a Kan complex. Then $f$ is a weak approximation to $\mathcal{O}^\otimes$ if and only if the following condition is satisfied:

$(\ast'')$ Let $C \in \mathcal{C}$ and let $\langle n \rangle = (p \circ f)(C) \in \mathbf{N}(\mathbf{Fin}_*)$. Then $f$ induces a weak homotopy equivalence

$$
\theta : \mathcal{C}/C \times_{\mathbf{N}(\mathbf{Fin}_*)/\langle n \rangle} \overline{\text{Tup}_n} \to \mathcal{O}^\otimes_{f(C)} \times_{\mathbf{N}(\mathbf{Fin}_*)/\langle n \rangle} \overline{\text{Tup}_n}.
$$

Remark 2.3.3.15. In the situation of Corollary 2.3.3.14, the assumption that $\mathcal{O}$ is a Kan complex guarantees that the $\infty$-category $\mathcal{O}^\otimes_{f(C)} \times_{\mathbf{N}(\mathbf{Fin}_*)/\langle n \rangle} \overline{\text{Tup}_n}$ is a Kan complex. However, in many applications, the $\infty$-category $\mathcal{C}/C \times_{\mathbf{N}(\mathbf{Fin}_*)/\langle n \rangle} \overline{\text{Tup}_n}$ will not be a Kan complex.

Proof. We may assume without loss of generality that $f$ is a categorical fibration, so that $\theta$ is also a categorical fibration. The map $\theta$ is a homotopy equivalence if and only if each of its homotopy fibers is weakly contractible. Since $\mathcal{O}^\otimes_{f(C)} \times_{\mathbf{N}(\mathbf{Fin}_*)/\langle n \rangle} \overline{\text{Tup}_n}$ is a Kan complex (Remark 2.3.3.15), we see that $\theta$ is a homotopy equivalence if and only if each fiber of $\theta$ is weakly contractible (Lemma 2.3.3.13). According to Proposition 2.3.3.11, this is equivalent to the requirement that $f$ be a weak approximation to $\mathcal{O}^\otimes$. □

Corollary 2.3.3.16. Let $\mathcal{O}^\otimes$ be an $\infty$-operad and let $f : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a map of generalized $\infty$-operads. Assume that the $\infty$-category $\mathcal{O}$ is a Kan complex. Then $f$ is a weak approximation if and only if, for every object $C \in \mathcal{C}^\otimes(n)$ and every active morphism $\alpha : \langle m \rangle \to \langle n \rangle$ in $\mathbf{Fin}_*$, the induced map

$$
\theta_{C, \alpha} : \mathcal{C}^\otimes_{f(C)} \times_{\mathbf{N}(\mathbf{Fin}_*)/\langle n \rangle} \{\langle m \rangle\} \to \mathcal{O}^\otimes_{f(C)} \times_{\mathbf{N}(\mathbf{Fin}_*)/\langle n \rangle} \{\langle m \rangle\}
$$

is a weak homotopy equivalence of simplicial sets.
Proof. For each $C \in \mathbf{C}_{(n)}$, we have a commutative diagram of simplicial sets

$$
\begin{array}{ccc}
\mathbf{C}_{/C} \times N(\mathcal{F}in_{+,})_{/C_{(n)}} & \xrightarrow{\theta_{\mathcal{C}}} & \mathbf{O}_{/f(C)} \times N(\mathcal{F}in_{+,})_{/C_{(n)}} \\
\text{Tup}_n & \xrightarrow{} & \text{Tup}_n,
\end{array}
$$

According to Proposition 2.3.3.14, the map $f$ is an approximation to $\mathbf{O}$ if and only if each of the maps $\theta_{\mathcal{C}}$ is a weak homotopy equivalence. This is equivalent to the requirement that $\theta_{\mathcal{C}}$ induces a weak homotopy equivalence after taking the homotopy fibers over any vertex of $\text{Tup}_n$, corresponding to an active morphism $\alpha : \langle m \rangle \to \langle n \rangle$. Using Lemma 2.3.3.13, we can identify the relevant map of homotopy fibers with $\theta_{\mathcal{C},n}$. \qed

For our next statement, we use the following notational convention: if $\mathbf{O}$ is an $\infty$-operad, we let $\mathbf{O}_{\text{act}}$ denote the subcategory of $\mathbf{O}$ spanned by the active morphisms.

**Corollary 2.3.3.17.** Let $f : \mathbf{C} \to \mathbf{O}$ be a map of $\infty$-operads. Assume that $\mathbf{C}$ and $\mathbf{O}$ are Kan complexes. The following conditions are equivalent:

(a) The map $f$ is an approximation.

(b) The map $f$ is a weak approximation.

(c) The map $f_{\text{act}} : \mathbf{C}_{\text{act}} \to \mathbf{O}_{\text{act}}$ is the composition of a categorical equivalence with a right fibration.

**Proof.** We may assume without loss of generality that $f$ is a fibration of $\infty$-operads. The implication $(a) \Rightarrow (b)$ follows from Lemma 2.3.3.10. We now show that $(b) \Rightarrow (c)$. Assume that $f$ is a weak approximation and choose an active morphism $\alpha : Y \to Z$ in $\mathbf{C}$; we wish to show that $\alpha$ is $f_{\text{act}}$-Cartesian. Unwinding the definitions, it will suffice to show that for every active morphism $\beta : X \to Z$ in $\mathbf{C}$, the induced map

$$
\theta : \text{Map}_{\mathbf{C}_{/Z}}(X,Y) \to \text{Map}_{\mathbf{O}_{/fZ}}(fX,fY)
$$

is a homotopy equivalence. Let $\alpha_0 : \langle m \rangle \to \langle n \rangle$ and $\beta_0 : \langle k \rangle \to \langle n \rangle$ be the images of $\alpha$ and $\beta$ in the $\infty$-category $N(\mathcal{F}in_{+,})$. Then $\theta$ is given by a disjoint union of maps

$$
\theta^\gamma : \text{Map}_{\mathbf{C}_{/Z}}(X,Y) \to \text{Map}_{\mathbf{O}_{/fZ}}(fX,fY),
$$

where $\gamma$ ranges over those maps $\langle k \rangle \to \langle m \rangle$ in $N(\mathcal{F}in_{+,})$ such that $\beta = \alpha \circ \gamma$ and the superscripts indicate the relevant summand of the mapping spaces. The map $\theta^\gamma$ is given by taking vertical homotopy fibers of the diagram

$$
\begin{array}{ccc}
\mathbf{C}_{/Y} \times N(\mathcal{F}in_{+,})_{/\langle m \rangle} & \xrightarrow{} & \mathbf{O}_{/Y} \times N(\mathcal{F}in_{+,})_{/\langle m \rangle} \\
\mathbf{C}_{/Z} \times N(\mathcal{F}in_{+,})_{/\langle n \rangle} & \xrightarrow{} & \mathbf{C}_{/Z} \times N(\mathcal{F}in_{+,})_{/\langle n \rangle}
\end{array}
$$

(the hypothesis that $\mathbf{O}$ and $\mathbf{C}$ are Kan complexes guarantee that the entries in this diagram are Kan complexes). It therefore suffices to show that the horizontal maps in the above diagram are homotopy equivalences, which follows from our assumption that $f$ is a weak approximation (Corollary 2.3.3.16).

We now complete the proof by showing that $(c) \Rightarrow (a)$. For any object $Z \in \mathbf{C}$ and any active morphism $\alpha_0 : Y_0 \to Z$, there is an essentially unique morphism $\alpha : Y \to Z$ in $\mathbf{C}$ lifting $\alpha_0$. We wish to show that $\alpha$ is $f$-Cartesian. Unwinding the definitions, we must show that for any morphism $\beta : X \to Z$ in $\mathbf{C}$, the map $f$ induces a homotopy $\text{Map}_{\mathbf{C}_{/Z}}(X,Y) \to \text{Map}_{\mathbf{O}_{/fZ}}(fX,fY)$. The map $\beta$ factors as a composition

$$
X \xrightarrow{\beta'} X' \xrightarrow{\beta''} Z
$$
where \( \beta' \) is inert and \( \beta'' \) is active. Since \( f \) is a map of \( \infty \)-operads, \( f(\beta') \) is inert and \( f(\beta'') \) is active; we may therefore replace \( \beta \) by \( \beta'' \) and thereby reduce to the case where \( \beta \) is active. The desired result now follows immediately from assumption (c).

**Corollary 2.3.3.18.** Suppose we are given maps of \( \infty \)-operads \( O^\otimes \xrightarrow{f} O'^\otimes \xrightarrow{g} O''^\otimes \), where \( O, O', \) and \( O'' \) are Kan complexes and \( g \) is an approximation. Then \( f \) is an approximation if and only if \( g \circ f \) is an approximation.

**Remark 2.3.3.19.** Let \( O^\otimes \) be an \( \infty \)-operad and let \( f : C^\otimes \to O^\otimes \) be a map of generalized \( \infty \)-operads. Assume that \( C^\otimes \) is a Kan complex. Then \( f \) is an approximation if and only if, for each object \( C \in C^\otimes \), the induced map of \( \infty \)-operads \( C \to O^\otimes \) is an approximation.

**Definition 2.3.3.20.** Let \( p : O^\otimes \to N(Fin_*) \) and \( q : O'^\otimes \to N(Fin_*) \) be \( \infty \)-operads, and let \( f : C \to O^\otimes \) be a weak approximation to \( O^\otimes \). Let \( f' = p \circ f \). We will say that a functor \( A : C \to O'^\otimes \) is an \( O^\otimes \)-algebra object of \( O'^\otimes \) if it satisfies the following conditions:

(a) The diagram of simplicial sets

\[
\begin{array}{ccc}
C & \xrightarrow{A} & O'^\otimes \\
\downarrow f & & \downarrow g \\
O^\otimes & \xrightarrow{p} & N(Fin_*)
\end{array}
\]

is commutative.

(b) Let \( C \in C \) be such that \( p'(C) = \langle n \rangle \), and for \( 1 \leq i \leq n \) choose a locally \( p' \)-coCartesian morphism \( \alpha_i : C \to C_i \in C \) covering the map \( p' : \langle n \rangle \to \langle 1 \rangle \). Then \( A(\alpha_i) \) is an inert morphism in \( O'^\otimes \).

We will say that a \( C \)-algebra object \( A \) of \( O'^\otimes \) is locally constant if it satisfies the following further condition:

(c) For every morphism \( \alpha \in C \) such that \( p'(\alpha) = \id_{\langle 1 \rangle} \), the image \( A(\alpha) \) is an equivalence in \( O' \).

We let \( \Alg_C(O') \) denote the full subcategory of \( \Fun_{N(Fin_*)}(C, O'^\otimes) \) spanned by the \( C \)-algebra objects of \( O'^\otimes \), and \( \Alg^\loc_C(O') \) the full subcategory of \( \Alg_C(O') \) spanned by the locally constant \( C \)-algebra objects of \( O'^\otimes \).

If \( f : C \to O^\otimes \) is an essential weak approximation, so that \( f \) factors as a composition \( C \xrightarrow{f'} C' \xrightarrow{f''} O^\otimes \) where \( f' \) is a categorical equivalence and \( f'' \) is a weak approximation, then we let \( \Alg^\loc_C(O') \) denote the full subcategory of \( \Fun_{N(D)_{\text{op}}}(C, O'^\otimes) \) given by the essential image of \( \Alg^\loc_C(O') \) under the equivalence of \( \infty \)-categories \( \Fun_{N(D)_{\text{op}}}(C', O'^\otimes) \to \Fun_{N(D)_{\text{op}}}(C, O'^\otimes) \) given by \( f' \), and \( \Alg^\loc_C(O') \) the essential image of \( \Alg^\loc_C(O') \).

**Example 2.3.3.21.** If \( O^\otimes \) is an \( \infty \)-operad and \( f : C \to O^\otimes \) is an essential weak approximation to \( O^\otimes \), then \( f \) is a \( C \)-algebra object of \( O^\otimes \).

**Example 2.3.3.22.** Let \( O^\otimes \) be an \( \infty \)-operad, and suppose we are given a map of generalized \( \infty \)-operads \( f : C^\otimes \to O^\otimes \). Assume that \( f \) is an essential weak approximation to \( O^\otimes \). For any other \( \infty \)-operad \( O'^\otimes \), a map \( A : C^\otimes \to O'^\otimes \) is a \( C^\otimes \)-algebra object of \( O'^\otimes \) (in the sense of Definition 2.3.3.20) if and only if it is a map of generalized \( \infty \)-operads (Definition 2.3.2.2); this follows from the argument of Remark 2.1.2.9.

Our main result in this section is the following:

**Theorem 2.3.3.23.** Let \( p : O^\otimes \to N(Fin_*) \) and \( q : O'^\otimes \to N(Fin_*) \) be \( \infty \)-operads, and let \( f : C \to O^\otimes \) be a weak approximation to \( O^\otimes \). Let \( \theta : \Alg^\loc_{O}(O') \to \Alg^\loc_{C}(O') \) be the map given by composition with \( f \), and let \( C_{(1)} \) denote the fiber \( C \times_{N(Fin_*)}\{1\} \).

Then:
(1) If $f$ induces an equivalence of $\infty$-categories $\mathcal{C}(1) \to \mathcal{O}$, then $\theta$ is an equivalence of $\infty$-categories.

(2) If $\mathcal{O}$ is a Kan complex and $f$ induces a weak homotopy equivalence $\mathcal{C}(1) \to \mathcal{O}$, then $\theta$ induces an equivalence of $\infty$-categories $\mathcal{Alg}_\mathcal{O}(\mathcal{O}') \to \mathcal{Alg}_\mathcal{O}^{\text{loc}}(\mathcal{O}')$.

Proof. Replacing $\mathcal{C}$ by an equivalent $\infty$-category if necessary, we may assume that $f$ is a categorical approximation. Choose a Cartesian fibration $u : M \to \Delta^1$ associated to the functor $f$, so that we have isomorphisms $\mathcal{O}^\otimes \simeq M \times \Delta^1 \{0\}$, $\mathcal{C} \simeq M \times \Delta^1 \{1\}$, and choose a retraction $r$ from $M$ onto $\mathcal{O}^\otimes$ such that $r|\mathcal{C} = f$. Let $X$ denote the full subcategory of $\text{Fun}_{N(Fin)}(M, \mathcal{O}^\otimes)$ spanned by those functors $F : M \to \mathcal{O}^\otimes$ satisfying the following conditions:

(i) The restriction $F|\mathcal{O}^\otimes$ belongs to $\mathcal{Alg}_\mathcal{O}(\mathcal{O}')$.

(ii) For every $u$-Cartesian morphism $\alpha$ in $M$, the image $F(\alpha)$ is an equivalence in $\mathcal{O}^\otimes$.

Condition (ii) is equivalent to the requirement that $F$ be a $q$-left Kan extension of $F|\mathcal{O}^\otimes$. Using Proposition T.4.3.2.15, we conclude that the restriction functor $X \to \mathcal{Alg}_\mathcal{O}(\mathcal{O}')$ is a trivial Kan fibration. Composition with $r$ determines a section $s$ of this trivial Kan fibration. Let $\psi : X \to \text{Fun}_{N(Fin)}(\mathcal{C}, \mathcal{O}^\otimes)$ be the other restriction functor. Then $\theta$ is given by the composition $\psi \circ s$. It will therefore suffice to show that $\psi$ determines an equivalence from $X$ onto $\mathcal{Alg}_\mathcal{O}(\mathcal{O}')$ (in case (1)) or $\mathcal{Alg}_\mathcal{O}^{\text{loc}}(\mathcal{O}')$ (in case (2)). In view of Proposition T.4.3.2.15, it will suffice to verify the following:

(a) Let $F_0 \in \mathcal{Alg}_\mathcal{C}(\mathcal{O}')$, and assume that $F_0$ is locally constant if we are in case (2). Then there exists a functor $F \in \text{Fun}_{N(Fin)}(M, \mathcal{O}^\otimes)$ which is a $q$-right Kan extension of $F_0$.

(b) A functor $F \in \text{Fun}_{N(Fin)}(M, \mathcal{O}^\otimes)$ belongs to $X$ if and only if $F$ is a $q$-right Kan extension of $F_0 = F|\mathcal{C}$, and $F_0 \in \mathcal{Alg}_\mathcal{C}(\mathcal{O}')$ (in case (1)) or $F_0 \in \mathcal{Alg}_\mathcal{O}^{\text{loc}}(\mathcal{O}')$ (in case (2)).

We begin by proving (a). Fix an object $X \in \mathcal{O}^\otimes$, let $\mathcal{C}_{X/}$ denote the fiber product $M_{X/} \times_M \mathcal{C}$, and let $F_X = F_0|\mathcal{C}_{X/}$. According to Lemma T.4.3.2.13, it will suffice to show that the functor $F_X$ can be extended to a $q$-limit diagram $\mathcal{C}_{X/}^\alpha \to \mathcal{O}^\otimes$ (covering the map $\mathcal{C}_{X/}^\alpha \to M^\otimes \to N(Fin_\infty)$). Let $\mathcal{C}_{X/}^\alpha$ denote the full subcategory of $\mathcal{C}_{X/}$ spanned by those morphisms $X \to C$ in $M$ which correspond to inert morphisms $X \to f(C)$ in $\mathcal{O}^\otimes$. Since $f$ is a weak approximation to $\mathcal{O}^\otimes$, Theorem T.4.1.3.1 implies that the inclusion $\mathcal{C}_{X/}^\alpha \hookrightarrow \mathcal{C}_{X/}$ is right cofinal. It will therefore suffice to show that the restriction $F_X' = F_X|\mathcal{C}_{X/}^\alpha$ can be extended to a $q$-limit diagram $\mathcal{C}_{X/}^\alpha \to \mathcal{O}^\otimes$.

Let $(n) = p(X)$, and let $\mathcal{C}_{X/}^{\alpha n}$ denote the full subcategory of $\mathcal{C}_{X/}^\alpha$ corresponding to inert morphisms $X \to f(C)$ for which $(p \circ f)(C) = (1)$. We claim that $F_X'$ is a $q$-right Kan extension of $F_X'' = F|\mathcal{C}_{X/}^{\alpha n}$. To prove this, let us choose an arbitrary object of $\mathcal{C}_{X/}^{\alpha n}$, given by a map $\alpha : X \to C$ in $M$. The fiber product $\mathcal{C}_{X/}^{\alpha n} \times_{\mathcal{C}_{X/}^\alpha} (\mathcal{C}_{X/}^\alpha)_{\alpha n}$ can be identified with the full subcategory of $M_{\alpha/}$ spanned by those diagrams $X \to C \to C'$ such that $(p \circ f)(\beta)$ has the form $\rho^i : (n) \to (1)$, for some $1 \leq i \leq n$. In particular, this $\infty$-category is a disjoint union of full subcategories $\{D(i)\}_{1 \leq i \leq n}$, where each $D(i)$ is equivalent to the full subcategory of $\mathcal{C}_{C'/}^{\alpha n}$ spanned by morphisms $C \to C'$ covering the map $\rho^i$. Our assumption that $f$ is a weak approximation to $\mathcal{O}^\otimes$ guarantees that each of these $\infty$-categories has a final object, given by a locally $(p \circ f)$-coCartesian morphism $C \to C_i$ in $\mathcal{O}$. It will therefore suffice to show that $F_0(C)$ is a $q$-product of the objects $\{F_0(C_i)\}_{1 \leq i \leq n}$. Since $\mathcal{O}^\otimes$ is an $\infty$-operad, we are reduced to proving that each of the maps $F_0(C) \to F_0(C_i)$ is inert, which follows from our assumption that $F_0 \in \mathcal{Alg}_\mathcal{C}(\mathcal{O}')$.

Using Lemma T.4.3.2.7, we are reduced to proving that the diagram $F_X''$ can be extended to a $q$-limit diagram $\mathcal{C}_{X/}^{\alpha n} \to \mathcal{O}^\otimes$ (covering the natural map $\mathcal{C}_{X/}^{\alpha n} \to M \to N(Fin_\infty)$). For $1 \leq i \leq n$, let $\mathcal{C}(i)^{\alpha n}_{X/}$ denote the full subcategory of $\mathcal{C}_{X/}^{\alpha n}$ spanned by those objects for which the underlying morphism $X \to C$ covers $\rho^i : p(X) \to (n) \to (1)$. Then $\mathcal{C}(i)^{\alpha n}_{X/}$ is the disjoint union of the full subcategories $\{\mathcal{C}(i)_{X/}^{\alpha n}\}$. Let $O(i)$ denote the full subcategory of $\mathcal{O}^\otimes \times_{N(Fin_\infty)} \{\rho^1\}$, so that we have a left fibration of simplicial sets $O(i) \to \mathcal{O}$ and
2.3. DISINTEGRATION AND ASSEMBLY

a categorical equivalence \( \mathcal{C}(i)'_{X/} \simeq \mathcal{O}(i) \times \mathcal{C}_{(1)} \). Choose inert morphisms \( X \to X_i \) in \( \mathcal{O}^{\otimes} \) for \( 1 \leq i \leq n \), so that each \( X_i \) determines an initial object of \( \mathcal{O}(i) \). If \( f \) induces a categorical equivalence \( \mathcal{C}_{(1)} \to \mathcal{O} \), then we can write \( X_i \simeq f(C_i) \) for some \( C_i \in \mathcal{C}_{(1)} \), and that the induced map \( X \to C_i \) can be identified with a final object of \( \mathcal{C}(i)'_{X/} \). Consequently, we are reduced to proving the existence of a \( q \)-product for the set of objects \( \{ F_0(C_i) \}_{1 \leq i \leq n} \), which follows from our assumption that \( \mathcal{O}^{\otimes} \) is an \( \infty \)-operad. This completes the proof of (a) in case (1).

In case (2), we must work a bit harder. Assume that \( \mathcal{O} \) is a Kan complex and that \( \mathcal{C}_{(1)} \to \mathcal{O} \) is a weak homotopy equivalence. We again have \( X_i \simeq f(C_i) \) for some \( C_i \in \mathcal{C}_{(1)} \). The map \( \mathcal{O}(i) \to \mathcal{O} \) is a left fibration and therefore a Kan fibration. Using the right-properness of the usual model structure on \( \text{Set}_\Delta \), we conclude that the diagram

\[
\begin{array}{ccc}
\mathcal{C}(i)'_{X/} & \longrightarrow & \mathcal{C}_{(1)} \\
\downarrow & & \downarrow \\
\mathcal{O}(i) & \longrightarrow & \mathcal{O}
\end{array}
\]

is a homotopy pullback diagram, so that \( \mathcal{C}(i)'_{X/} \to \mathcal{O}(i) \) is a weak homotopy equivalence and therefore \( \mathcal{C}(i)'_{X/} \) is weakly contractible. Since \( F_0 \) is locally constant, Corollary T.4.4.10 and Proposition T.4.3.1.5 imply that \( F_0 \) is a \( q \)-right Kan extension of \( F_0 \) if and only if, for every object \( X \in \mathcal{O}^{\otimes} \), if we choose \( C_i \in \mathcal{C}_{(1)} \) and maps \( \alpha_i : X \to C_i \) in \( \mathcal{M} \) having image \( \rho^i : \langle n \rangle \to \langle 1 \rangle \) in \( \text{Fin} \) for \( 1 \leq i \leq n \), then \( F(\alpha) \) is an inert morphism in \( \mathcal{O}^{\otimes} \) for \( 1 \leq i \leq n \).

We now prove (b). Assume first that \( F \in \mathcal{X} \). Then \( F_0 = F|_{\mathcal{C}} \in \text{Alg}_{\mathcal{C}}(\mathcal{O'}) \) (in case (1)) or \( F_0 = F|_{\mathcal{C}} \in \text{Alg}^{\text{loc}}_{\mathcal{C}}(\mathcal{O'}) \) (in case (2)). Then \( F \) is a \( q \)-right Kan extension of \( F_0 \) if and only if, for every object \( X \in \mathcal{O}^{\otimes} \), if we choose \( C_i \in \mathcal{C}_{(1)} \) and maps \( \alpha_i : X \to C_i \) in \( \mathcal{M} \) having image \( \rho^i : \langle n \rangle \to \langle 1 \rangle \) in \( \text{Fin} \) for \( 1 \leq i \leq n \), then \( F(\alpha) \) is an inert morphism in \( \mathcal{O}^{\otimes} \) for \( 1 \leq i \leq n \).

We now prove (b). Assume first that \( F \in \mathcal{X} \). Then \( F_0 = F|_{\mathcal{C}} \) is equivalent to the functor \( (F|_{\mathcal{O}^{\otimes}}) \circ f \). It follows immediately that \( F_0 \in \text{Alg}_{\mathcal{C}}(\mathcal{O'}) \). In case (2), the assumption that \( \mathcal{O} \) is a Kan complex immediately implies that \( F_0 \) is locally constant. Criterion (b') immediately implies that \( F \) is a \( q \)-right Kan extension of \( F_0 \). This proves the "only if" direction.

For the converse, assume that \( F_0 \in \text{Alg}_{\mathcal{C}}(\mathcal{O'}) \), that \( F_0 \) is locally constant if we are in case (2), and that \( F \) is a \( q \)-right Kan extension of \( F_0 \). We wish to prove that \( F \in \mathcal{X} \). We first verify that \( F \) satisfies (ii). Pick an object \( C \in \mathcal{C} \) and choose locally \((p \circ f)\)-coCartesian morphisms \( \alpha_i : C \to C_i \) for \( 1 \leq i \leq n \). Let \( X = f(C) \); we wish to show that the induced map \( F(X) \to F(C) \) is an equivalence in \( \mathcal{O}^{\otimes} \). Since \( \mathcal{O}^{\otimes} \) is an \( \infty \)-operad, and the maps \( F_0(C) \to C_0(C_i) \) are inert for \( 1 \leq i \leq n \) (by virtue of our assumption that \( F \in \text{Alg}_{\mathcal{C}}(\mathcal{O'}) \)), it will suffice to show that each of the maps \( F(X) \to F_0(C_i) \) is inert, which follows from (b').

To complete the proof, we must show that \( F|_{\mathcal{O}^{\otimes}} \) is a map of \( \infty \)-operads. In view of Remark 2.1.2.9, it will suffice to show that if \( X \in \mathcal{O}^{\otimes}_{(n)} \) and \( \alpha : X \to X_i \) is an inert morphism of \( \mathcal{O}^{\otimes} \) covering the map \( \rho^i : \langle n \rangle \to \langle 1 \rangle \) for \( 1 \leq i \leq n \), then the induced map \( F(X) \to F(X_i) \) is an inert morphism in \( \mathcal{O}^{\otimes} \). Arguing as above, we can assume that \( X_i = f(C_i) \). Condition (ii) implies that \( F(X_i) \to F(C_i) \) is an equivalence in \( \mathcal{O}^{\otimes} \); it will therefore suffice to show that the composite map \( F(X) \to F(X_i) \to F(C_i) \) is inert, which follows from criterion (b').

\[ \square \]

**Corollary 2.3.3.24.** Let \( f : \mathcal{C}^{\otimes} \to \mathcal{O}^{\otimes} \) be a map of \( \infty \)-operads. Assume that \( f \) is a weak approximation to \( \mathcal{O}^{\otimes} \) and that \( f \) induces an equivalence of \( \infty \)-categories \( \mathcal{C} \to \mathcal{O} \). Then \( f \) is an equivalence of \( \infty \)-operads.

**Proof.** Theorem 2.3.3.23 implies that for every \( \infty \)-operad \( \mathcal{O}^{\otimes} \), composition with \( f \) induces an equivalence of \( \infty \)-categories \( \text{Alg}_\mathcal{O}(\mathcal{O'}) \to \text{Alg}_{\mathcal{C}}(\mathcal{O'}) \). \[ \square \]
2.3.4 Disintegration of $\infty$-Operads

In §2.3.1, we introduced the definition of a unital $\infty$-operad. Roughly speaking, an $\infty$-operad $\mathcal{O}^\otimes$ is unital if there is no information contained in its spaces of nullary operations (more precisely, if these spaces are contractible). We now introduce a stronger condition, which guarantees also that the unary operation spaces of $\mathcal{O}^\otimes$ are trivial:

**Definition 2.3.4.1.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad. We will say that $\mathcal{O}^\otimes$ is reduced if $\mathcal{O}^\otimes$ is unital and the underlying $\infty$-category $\mathcal{O}$ is a contractible Kan complex.

Our main goal in this section is to show that if $\mathcal{O}^\otimes$ is an arbitrary unital $\infty$-operad whose underlying $\infty$-category $\mathcal{O}$ is a Kan complex, then $\mathcal{O}^\otimes$ can be obtained by assembling a $\mathcal{O}$-family of reduced $\infty$-operads (Theorem 2.3.4.4). A precise formulation will make use of the following generalization of Definition 2.3.4.1:

**Definition 2.3.4.2.** We will say that an $\infty$-operad family $\mathcal{O}^\otimes$ is reduced if $\mathcal{O}^\otimes_{(0)}$ is a Kan complex and, for each object $X \in \mathcal{O}^\otimes_{(0)}$, the $\infty$-operad $\mathcal{O}^\otimes_{(0)}/X$ is reduced.

**Remark 2.3.4.3.** Let $\mathcal{C}$ be a Kan complex, and let $q : \mathcal{O}^\otimes \to \mathcal{C} \times \mathcal{N}(\text{Fin}_\ast)$ be a $\mathcal{C}$-family of $\infty$-operads. Every object $X \in \mathcal{O}^\otimes_{(0)}$ is $q$-final, so that we have a trivial Kan fibration $\mathcal{O}^\otimes_{(0)}/X \to \mathcal{C}/C \times \mathcal{N}(\text{Fin}_\ast)$, where $C$ denotes the image of $X$ in $\mathcal{C}$. Since $\mathcal{C}$ is a Kan complex, the $\infty$-category $\mathcal{C}/C$ is a contractible Kan complex, so that $\mathcal{O}^\otimes_{(0)}/X$ is equivalent to the $\infty$-operad $\mathcal{O}^\otimes_{C} = \mathcal{O}^\otimes \times_{\mathcal{C}} \{C\}$.

It follows that $\mathcal{O}^\otimes$ is reduced (in the sense of Definition 2.3.4.2) if and only if $\mathcal{C}$ is reduced and each fiber $\mathcal{O}^\otimes_{C}$ is a reduced $\infty$-operad (in the sense of Definition 2.3.4.1). In particular, an $\infty$-operad is reduced if and only if it is reduced when regarded as a generalized $\infty$-operad.

We are now ready to state the main result of this section.

**Theorem 2.3.4.4.** Let $\text{Op}_{\mathcal{O},n,rd}^\infty$ denote the full subcategory of $\text{Op}_{\mathcal{O}}^\infty$ spanned by the reduced generalized $\infty$-operads. Then the assembly functor $\text{Assem} : \text{Op}_{\mathcal{O},n,rd}^\infty \to \text{Op}_{\mathcal{O}}^\infty$ induces an equivalence from $\text{Op}_{\mathcal{O},n,rd}^\infty$ to the full subcategory of $\text{Op}_{\mathcal{O}}^\infty$ spanned by those unital $\infty$-operads $\mathcal{O}^\otimes$ such that the underlying Kan complex of $\mathcal{O}$ is a Kan complex.

In other words, if $\mathcal{O}^\otimes$ is a unital $\infty$-operad such that $\mathcal{O}$ is a Kan complex, then $\mathcal{O}^\otimes$ can be obtained (in an essentially unique way) as the assembly of a family of reduced $\infty$-operads. The proof of Theorem 2.3.4.4 is based on the following assertion, which we will prove at the end of this section:

**Proposition 2.3.4.5.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad and let $f : \mathcal{O}^\otimes \to \mathcal{O}'^\otimes$ be a map of generalized $\infty$-operads. Assume that $\mathcal{O}^\otimes_{(0)}$, $\mathcal{O}$, and $\mathcal{O}'$ are Kan complexes. Then:

1. If $f$ is a weak approximation to $\mathcal{O}'^\otimes$ which induces a homotopy equivalence $\mathcal{O} \to \mathcal{O}'$, then $f$ exhibits $\mathcal{O}^\otimes$ as an assembly of $\mathcal{O}'^\otimes$.
2. Assume that for each object $X \in \mathcal{O}^\otimes_{(0)}$, the $\infty$-operad $\mathcal{O}^\otimes_{(0)}/X$ is unital. If $f$ exhibits $\mathcal{O}^\otimes$ as an assembly of $\mathcal{O}^\otimes$, then $f$ is an approximation to $\mathcal{O}'^\otimes$ and the underlying map $\mathcal{O} \to \mathcal{O}'$ is a homotopy equivalence of Kan complexes. Moreover, the $\infty$-operad $\mathcal{O}'^\otimes$ is also unital.

The proofs of Theorem 2.3.4.4 and Proposition 2.3.4.5 will use some ideas from later in this book.

**Proof of Theorem 2.3.4.4.** It follows from Proposition 2.3.4.5 that the assembly functor $\text{Assem}$ carries $\text{Op}_{\mathcal{O},n,rd}^\infty$ into the full subcategory $\mathcal{X} \subseteq \text{Op}_{\mathcal{O}}^\infty$ spanned by those unital $\infty$-operads $\mathcal{O}^\otimes$ such that $\mathcal{O}$ is a Kan complex. We next show that $\text{Assem} : \text{Op}_{\mathcal{O},n,rd}^\infty \to \mathcal{X}$ is essentially surjective. Let $\mathcal{O}^\otimes$ be such a unital $\infty$-operad whose underlying $\infty$-category is a Kan complex, and choose a homotopy equivalence $u_0 : \mathcal{O} \to S$ for some Kan complex $S$ (for example, we can take $S = \mathcal{O}$ and $u_0$ to be the identity map). Let $S^H$ be the $\infty$-operad defined in §2.4.3. Using Proposition 2.4.3.9, we can extend $u_0$ to an $\infty$-operad map $u : \mathcal{O}^\otimes \to S^H$. Replacing
2.3. DISINTEGRATION AND ASSEMBLY

$\mathcal{O}^{\otimes}$ by an equivalent $\infty$-operad if necessary, we may suppose that $u$ is a fibration of $\infty$-operads. Let $\mathcal{O}^{\otimes}$ be the fiber product $\mathcal{O}^{\otimes} \times_{\text{su}} (S \times N(\text{Fin}_s))$. Then $\mathcal{O}^{\otimes}$ is an $S$-family of $\infty$-operads equipped with a map $f: \mathcal{O}^{\otimes} \to \mathcal{O}$ which induces an isomorphism $\mathcal{O}' \to \mathcal{O}$. The map $f$ is a pullback of the approximation $S \times N(\text{Fin}_s) \to S^U$ of Remark 2.4.3.6, and is therefore an approximation to $\mathcal{O}^{\otimes}$ (Remark 2.3.3.9). Invoking Proposition 2.3.4.5, we deduce that $f$ exhibits $\mathcal{O}^{\otimes}$ as an assembly of $\mathcal{O}^{\otimes}$, so that we have an equivalence $\text{Assem}(\mathcal{O}^{\otimes}) \simeq \mathcal{O}^{\otimes}$. To deduce the desired essential surjectivity, it suffices to show that $\mathcal{O}^{\otimes}$ is reduced. In other words, we must show that for each $s \in S$, the $\infty$-operad $\mathcal{O}_s^{\otimes} \simeq \mathcal{O}^{\otimes} \times_{\text{su}} N(\text{Fin}_s)$ is reduced. This is clear: the underlying $\infty$-category $\mathcal{O}_s$ is given by the fiber of a trivial Kan fibration $f: \mathcal{O} \to S$, and $\mathcal{O}_s^{\otimes}$ is unital because it is a homotopy fiber product of unital $\infty$-operads.

We now show that $\text{Assem}: \text{Op}_{\text{gen}}^{\text{nd}} \to \text{Op}_{\infty}$ is fully faithful. Let $\mathcal{C}^{\otimes}$ and $\mathcal{D}^{\otimes}$ be reduced generalized $\infty$-operads, and choose assembly maps $\mathcal{C}^{\otimes} \to \mathcal{C}^{\otimes}$ and $\mathcal{D}^{\otimes} \to \mathcal{D}^{\otimes}$. We will show that the canonical map $\text{Alg}_C(\mathcal{D}) \to \text{Alg}_C(\mathcal{O}) \simeq \text{Alg}_C'(\mathcal{O})$ is an equivalence of $\infty$-categories. As above, we choose a Kan complex $S \simeq \mathcal{O}$ and a fibration of $\infty$-operads $\mathcal{O}^{\otimes} \to S^U$, and define $\mathcal{O}^{\otimes}$ to be the fiber product $(S \times N(\text{Fin}_s)) \times_{\text{su}} \mathcal{O}^{\otimes}$. Using the equivalences $\text{Alg}_C(S^U) \simeq \text{Fun}(\mathcal{C}, S)$ and $\text{Alg}_C(S \times N(\text{Fin}_s)) \simeq \text{Fun}(\mathcal{C}^{\otimes}_0, S)$ provided by Propositions 2.4.3.16 and 2.3.2.9, we obtain a homotopy pullback diagram of $\infty$-categories

\[
\begin{array}{ccc}
\text{Alg}_C(\mathcal{O}') & \longrightarrow & \text{Alg}_C(\mathcal{O}) \\
\downarrow & & \downarrow \\
\text{Fun}(\mathcal{C}^{\otimes}_0, S) & \longrightarrow & \text{Fun}(\mathcal{C}, S).
\end{array}
\]

Here the lower horizontal map is obtained by composing with the functor $\mathcal{C} = \mathcal{C}^{\otimes}_{(1)} \to \mathcal{C}^{\otimes}_{(0)}$ induced by the map $(1) \to (0)$ in $\text{Fin}_s$. Since $\mathcal{C}$ is reduced, this map is an equivalence of $\infty$-categories, so the natural map $\text{Alg}_C(\mathcal{O}') \to \text{Alg}_C(\mathcal{O})$ is an equivalence. Similarly, we have an equivalence $\text{Alg}_D(\mathcal{O}') \to \text{Alg}_D(\mathcal{O})$. We may therefore assume that the assembly map $\mathcal{D}^{\otimes} \to \mathcal{O}^{\otimes}$ factors through a map of generalized $\infty$-operads $\gamma: \mathcal{D}^{\otimes} \to \mathcal{O}^{\otimes}$. To complete the proof, it will suffice to show that $\gamma$ is an equivalence of generalized $\infty$-operads (and therefore induces an equivalence of $\infty$-categories $\text{Alg}_C(\mathcal{O}) \to \text{Alg}_C(\mathcal{O}^{\otimes}) \simeq \text{Alg}_C'(\mathcal{O})$).

Replacing $\mathcal{D}^{\otimes}$ by an equivalent generalized $\infty$-operad if necessary, we can assume that $\gamma: \mathcal{D}^{\otimes} \to \mathcal{O}^{\otimes}$ is a categorical fibration, so that the composite map $\mathcal{D}^{\otimes} \to \mathcal{O}^{\otimes} \to S \times N(\text{Fin}_s)$ exhibits $\mathcal{D}$ as an $S$-family of $\infty$-operads. It will therefore suffice to show that for each $s \in S$, the induced map of fibers $\gamma_s: \mathcal{D}_s^{\otimes} \to \mathcal{O}_s^{\otimes}$ is an equivalence of $\infty$-operads. For each $D \in \mathcal{D}_s^{\otimes}$ having an image $X \in \mathcal{O}_s^{\otimes}$, we have a commutative diagram

\[
\begin{array}{ccc}
(\mathcal{D}^{\otimes})_{/D} & \longrightarrow & (\mathcal{O}^{\otimes})_{/X} \\
\downarrow & & \downarrow \\
(\mathcal{O}_s^{\otimes})_{/D} & \longrightarrow & (\mathcal{O}_s^{\otimes})_{/X},
\end{array}
\]

where the superscript indicates that we consider the subcategory spanned by active morphisms. The horizontal maps in this diagram are categorical equivalences (by Proposition 2.3.4.5 and Corollary 2.3.3.17). It follows that the vertical maps are also categorical equivalences, so that $\gamma_s$ is an approximation between reduced $\infty$-operads. It follows from Corollary 2.3.3.24 that $\gamma_s$ is an equivalence of $\infty$-operads as desired.

We now turn to the proof of Proposition 2.3.4.5. We will need several preliminary results.

**Lemma 2.3.4.6.** Let $f: X \to Y$ be a map of simplicial sets. If $f$ is a weak homotopy equivalence and $Y$ is a Kan complex, then $f$ is left cofinal.

**Proof.** The map $f$ factors as a composition $X \xrightarrow{f'} X' \xrightarrow{f''} Y$, where $f'$ is a categorical equivalence and $f''$ is a categorical fibration. Replacing $f$ by $f''$, we can reduce to the case where $f$ is a categorical fibration so
that $X$ is an $\infty$-category. According to Theorem T.4.1.3.1, it suffices to show that for every vertex $y \in Y$, the fiber product $X \times_Y Y_{y/}$ is weakly contractible. Consider the pullback diagram

$$
\begin{array}{ccc}
X \times_Y Y_{y/} & \xrightarrow{f'} & Y_{y/} \\
\downarrow & & \downarrow g \\
X & \xrightarrow{f} & Y.
\end{array}
$$

The map $g$ is a left fibration over a Kan complex, and therefore a Kan fibration (Lemma T.2.1.3.3). Since the usual model structure on simplicial sets is right proper, our diagram is a homotopy pullback square. Because $f$ is a weak homotopy equivalence, we deduce that $f'$ is a weak homotopy equivalence. Since $Y_{y/}$ is weakly contractible, we deduce that $X \times_Y Y_{y/}$ is weakly contractible, as desired.

**Lemma 2.3.4.7.** Let $f : X \to Y$ be a weak homotopy equivalence of simplicial sets, let $\mathcal{C}$ be an $\infty$-category, and let $\bar{p} : Y^\circ \to \mathcal{C}$ be a colimit diagram. Suppose that $\bar{p}$ carries every edge of $Y$ to an equivalence in $\mathcal{C}$. Then the composite map $X^\circ \to Y^\circ \to \mathcal{C}$ is a colimit diagram.

**Proof.** Let $C \in \mathcal{C}$ be the image under $\bar{p}$ of the cone point of $Y^\circ$. Let $C_\infty$ be the largest Kan complex contained in $\mathcal{C}$, so that $\bar{p}$ induces a map $p : Y \to C_\infty$. Factor the map $p$ as a composition

$$
Y \xrightarrow{p'} Z \xrightarrow{p''} C_\infty,
$$

where $p'$ is anodyne and $p''$ is a Kan fibration (so that $Z$ is a Kan complex). Lemma 2.3.4.6 guarantees that the inclusion $Y \to Z$ is left cofinal and therefore right anodyne (Proposition T.4.1.1.3). Applying this observation to the lifting problem

$$
\begin{array}{ccc}
Y & \to & C_{/C} \\
\downarrow & & \downarrow \\
Z & \xrightarrow{p''} & C,
\end{array}
$$

we deduce that $\bar{p}$ factors as a composition

$$
Y^\circ \to Z^\circ \xrightarrow{\overline{q}} C.
$$

Since $p'$ is left cofinal, the map $\overline{q}$ is a colimit diagram. Lemma 2.3.4.6 also guarantees that the composition $f \circ p' : X \to Z$ is left cofinal, so that

$$
X^\circ \to Z^\circ \xrightarrow{\overline{q}} C
$$

is also a colimit diagram. □

For the next statements, we will assume that the reader is familiar with the theory of free algebras that we discuss in §3.1.3.

**Proposition 2.3.4.8.** Let $f : O^\otimes \to O'^\otimes$ be a map between small $\infty$-operads, and let $O^\otimes$ be a symmetric monoidal $\infty$-category. Assume that $\mathcal{C}$ admits small colimits, and that the tensor product on $\mathcal{C}$ preserves small colimits in each variable, and let $F : \text{Fun}(O, \mathcal{C}) \to \text{Alg}_O(\mathcal{C})$ and $F' : \text{Fun}(O', \mathcal{C}) \to \text{Alg}_{O'}(\mathcal{C})$ be left adjoints to the forgetful functors (Example 3.1.3.6). The commutative diagram of forgetful functors

$$
\begin{array}{ccc}
\text{Alg}_{O'}(\mathcal{C}) & \xrightarrow{\theta} & \text{Alg}_O(\mathcal{C}) \\
\downarrow & & \downarrow \\
\text{Fun}(O', \mathcal{C}) & \xrightarrow{\theta'} & \text{Fun}(O, \mathcal{C})
\end{array}
$$

induces a natural transformation $\alpha : F \circ \theta' \to \theta \circ F'$ from $\text{Fun}(O', \mathcal{C})$ to $\text{Alg}_O(\mathcal{C})$. Assume that $O'$ is a Kan complex.
2.3. DISINTEGRATION AND ASSEMBLY

(1) If \( f \) is a weak approximation to \( \mathcal{O}_T \) then the natural transformation \( \alpha \) is an equivalence.

(2) Conversely, suppose that \( \alpha \) is an equivalence in the special case where \( \mathcal{C} = S \) (equipped with the Cartesian monoidal structure) and when evaluated on the constant functor \( \mathcal{O}' \to \mathcal{C} \) taking the value \( \Delta^0 \). Then \( f \) is an approximation to \( \mathcal{O}_T \).

Proof. Fix a map \( A_0 \in \text{Fun}(\mathcal{O}', \mathcal{C}) \) and let \( X \in \mathcal{O} \). Let \( X \) be the subcategory of \( \mathcal{O}_T \) whose objects are active maps \( Y \to X \) in \( \mathcal{O}_T \) and whose morphisms are maps which induce equivalences in \( \text{N}(\text{Fin}_\ast) \), and let \( X' \subseteq \mathcal{O}_T \) be defined similarly. Then \( A_0 \) determines diagrams \( \chi : X \to \mathcal{C} \) and \( \chi' : X' \to \mathcal{C} \) (here \( \chi \) is given by composing \( \chi' \) with the map \( X \to X' \) induced by \( \gamma \)). Using the characterization of free algebras given in §3.1.3, we deduce that \( \alpha(A_0)(X) : (F \circ \theta')(A_0)(X) \to (\theta \circ F')(A_0)(X) \) is given by the evident map \( \colim_X \chi \to \colim_{X'} \chi' \). Since \( \mathcal{O}' \) is a Kan complex, \( A_0 \) carries every morphism in \( \mathcal{O}' \) to an equivalence in \( \mathcal{C} \); then \( \chi' \) carries every morphism in \( \mathcal{C} \) to an equivalence in \( \mathcal{C} \). If \( f \) is an approximation to \( \mathcal{O}_T \), then the evident map \( X \to X' \) is a weak homotopy equivalence (Corollary 2.3.3.16) that \( \alpha \) is an equivalence by Lemma 2.3.4.7: this proves (1).

Conversely, suppose that the hypotheses of (2) are satisfied. Taking \( A_0 \) to be the constant functor taking the value \( \Delta^0 \in \mathcal{S} \), we deduce from Corollary T.3.3.4.6 that the map \( X \to X' \) is a weak homotopy equivalence for each \( X \in \mathcal{O} \). From this it follows that \( f \) satisfies the criterion of Corollary 2.3.3.16 and is therefore an approximation to \( \mathcal{O}_T \).

Proposition 2.3.4.9. Let \( S \) be a Kan complex, let \( \mathcal{O}_T : \mathcal{O}_T \to S \times \text{N}(\text{Fin}_\ast) \) be an \( \mathcal{S} \)-family of \( \mathcal{O} \)-operads, and let \( \mathcal{O}_S \) be a symmetric monoidal \( \infty \)-category. Suppose that, for each \( s \in S \), the restriction functor \( \text{Alg}(\mathcal{O}_S(\mathcal{C})) \to \text{Fun}(\mathcal{O}_S, \mathcal{C}) \) admits a left adjoint \( F_s \). Then:

(1) The restriction functor \( \theta : \text{Alg}(\mathcal{O}_S(\mathcal{C})) \to \text{Fun}(\mathcal{O}_S, \mathcal{C}) \) admits a left adjoint \( F \).

(2) Let \( A \in \text{Alg}(\mathcal{O}_S(\mathcal{C})) \), let \( B \in \text{Fun}(\mathcal{O}_S, \mathcal{C}) \), and let \( \alpha : B \to \theta(A) \) be a morphism in \( \text{Fun}(\mathcal{O}_S, \mathcal{C}) \). Then the adjoint map \( F(\alpha) \) is an equivalence in \( \text{Alg}(\mathcal{O}_S(\mathcal{C})) \) if and only if, for each \( s \in S \), the underlying map \( F_s(B|\mathcal{O}_S) \to A|\mathcal{O}_S^\otimes \) is an equivalence in \( \text{Alg}(\mathcal{O}_S(\mathcal{C})) \).

Proof. Fix \( B \in \text{Fun}(\mathcal{O}_S, \mathcal{C}) \). For every map of simplicial sets \( \psi : T \to S \), let \( \mathcal{O}_T = \mathcal{O} \times_T \mathcal{S} \), \( B_T = B|\mathcal{O}_T \), and \( X(T) \) denote the full subcategory of \( \text{Alg}(\mathcal{O}_T(\mathcal{C})) \times \text{Fun}(\mathcal{O}_T, \mathcal{C}) \text{Fun}(\mathcal{O}(\mathcal{C}), \mathcal{B}_T)/T \) spanned by those objects \( (A_T \in \text{Alg}(\mathcal{O}_T(\mathcal{C})), \phi : B_T \to A_T|\mathcal{O}_T) \) such that, for each vertex \( t \in T \), the induced map \( \mathcal{F}_\psi(t)B_T|\mathcal{O}_\psi(t) \to A_T|\mathcal{O}_\psi(t) \) is an equivalence. We claim that every inclusion of simplicial sets \( i : T' \hookrightarrow T \) in \( \text{Set}_\Delta/\mathcal{S} \), the restriction map \( X(T) \to X(T') \) is a trivial Kan fibration. The collection of maps \( i \) for which the conclusion holds is clearly weakly saturated; it therefore suffices to prove the claim in the case where \( i \) is an inclusion of the form \( \partial \Delta^n \subseteq \Delta^n \). The proof proceeds by induction on \( n \). The inductive hypothesis implies that the restriction map \( X(\partial \Delta^n) \to X(\emptyset) \simeq \Delta^0 \) is a trivial Kan fibration, so that \( X(\partial \Delta^n) \) is a contractible Kan complex.

The map \( X(\Delta^n) \to X(\partial \Delta^n) \) is evidently a categorical fibration; it therefore suffices to show that it is a categorical equivalence. In other words, it suffices to show that \( X(\Delta^n) \) is also a contractible Kan complex. Let \( s \in S \) denote the image of the vertex \( \{0\} \in \Delta^n \in S \). Since the inclusion \( \mathcal{O}_s^\otimes \to \mathcal{O}_S^\otimes \) is a categorical equivalence, it induces a categorical equivalence \( X(\Delta^n) \to X(\{s\}) \). We are therefore reduced to proving that \( X(\{s\}) \) is a contractible Kan complex, which is obvious.

The above argument shows that \( X(S) \) is a contractible Kan complex; in particular, \( X(S) \) is nonempty. Consequently, there exists a map \( \phi : B \to \theta(A) \) satisfying the condition described in (2). We will prove (1) together with the “if” direction of (2) by showing that \( \phi \) induces a homotopy equivalence \( \rho : \text{Map}_{\text{Alg}(\mathcal{O}_S)}(A, C) \to \text{Map}_{\text{Alg}(\mathcal{O}_S)}(B, \theta(C)) \) for each \( C \in \text{Alg}(\mathcal{O}_S) \). The “only if” direction of (2) will then follow by the usual uniqueness argument. We proceed as before: for every map of simplicial sets \( T \to S \), let \( Y(T) \) denote the \( \infty \)-category \( \text{Alg}(\mathcal{O}_S(\mathcal{C}))_{(A|\mathcal{O}_S/\mathcal{T})} \times \text{Fun}(\mathcal{O}_T, \mathcal{C})_{(A_T|\mathcal{O}_T/\mathcal{T})} \text{Fun}(\mathcal{O}_S, \mathcal{C})_{(B|\mathcal{O}_T/\mathcal{T})} \) and \( Y(T) = \text{Fun}(\mathcal{O}_T, \mathcal{C})_{(B|\mathcal{O}_T/\mathcal{T})} \). The map \( \rho \) can be regarded as a pullback of the restriction map \( Y(S) \to Y'(S) \). To complete the proof, it will suffice to show that \( Y(S) \to Y'(S) \) is a trivial Kan fibration. We will prove the following stronger assertion: for every inclusion \( T' \hookrightarrow T \) in \( \text{Set}_\Delta/\mathcal{S} \), the restriction map \( \pi : Y(T) \to Y(T') \times_{Y'(T')} Y'(T) \) is a
trivial Kan fibration. As before, the collection of inclusions which satisfy this condition is weakly saturated, so we may reduce to the case where \( T = \Delta^n, T' = \partial \Delta^n \), and the result holds for inclusions of simplicial sets having dimension \(< n \). Moreover, since \( \pi \) is easily seen to be a categorical fibration, it suffices to show that \( \pi \) is a categorical equivalence. Using the inductive hypothesis, we deduce that \( Y(T') \to Y'(T') \) is a trivial Kan fibration, so that the pullback map \( Y(T') \times_{Y'(T')} Y'(T) \to Y'(T) \) is a categorical equivalence. By a two-out-of-three argument, we are reduced to proving that the restriction map \( Y(T) \to Y'(T) \) is a categorical equivalence. If we define \( s \) to be the image of \( \{0\} \subseteq \Delta^n \simeq T \) in \( S \), then we have a commutative diagram

\[
\begin{array}{ccc}
Y(T) & \longrightarrow & Y'(T) \\
\downarrow & & \downarrow \\
Y(\{s\}) & \longrightarrow & Y'(\{s\})
\end{array}
\]

in which the vertical maps are categorical equivalences. We are therefore reduced to showing that \( Y(\{s\}) \to Y'(\{s\}) \) is a categorical equivalence, which is equivalent to the requirement that the map \( F_\pi(B|0, s) \to A|0^\odot \) be an equivalence in \( \text{Alg}_{0^\odot}(C) \).

We conclude this section with the proof of Proposition 2.3.4.5.

**Proof of Proposition 2.3.4.5.** Assertion (1) is an immediate consequence of Theorem 2.3.3.23. We will prove (2). Assume that \( f : 0^\odot \to 0'^\odot \) exhibits \( 0'^\odot \) as an assembly of \( 0^\odot \) and that the \( \infty \)-operad \( 0^\odot_{/X} \) is reduced for each \( X \in 0^\odot_{(0)} \). We wish to prove:

(a) The \( \infty \)-operad \( 0'^\odot \) is unital.

(b) The map \( f \) is an approximation to \( 0'^\odot \).

(c) The map \( f \) induces a homotopy equivalence of Kan complexes \( 0 \to 0' \).

It follows from Proposition 2.3.1.11 that for each \( s \in S \), the induced map \( \text{Alg}_{0^\odot}(0^\odot_s) \to \text{Alg}_{0^\odot}(0) \) is a trivial Kan fibration. Arguing as in Proposition 2.3.4.9, we deduce that \( \text{Alg}_{0}(0^\odot'_s) \to \text{Alg}_{0}(0^\odot') \) is a trivial Kan fibration. Since \( f \) exhibits \( 0'^\odot \) as an assembly of \( 0^\odot \), we deduce that the map \( \text{Alg}_{0^\odot}(0^\odot'_s) \to \text{Alg}_{0^\odot}(0^\odot') \) is an equivalence of \( \infty \)-categories, and therefore (since it is a categorical fibration) a trivial Kan fibration. In particular, the projection map \( 0'^\odot \to 0^\odot \) admits a section, so the final object of \( 0^\odot \) is initial and \( 0'^\odot \) is also unital. This proves (a).

Let \( C \) be an arbitrary \( \infty \)-category, which we regard as the underlying \( \infty \)-category of the \( \infty \)-operad \( C^UI \). We have a commutative diagram

\[
\begin{array}{ccc}
\text{Alg}_{0^\odot}(C) & \longrightarrow & \text{Alg}_{0}(C) \\
\downarrow & & \downarrow \\
\text{Fun}(0^\odot', C) & \longrightarrow & \text{Fun}(0, C)
\end{array}
\]

where the upper horizontal map is an equivalence and the vertical maps are equivalences by virtue of Proposition 2.4.3.16. It follows that the lower horizontal map is an equivalence. Allowing \( C \) to vary, we deduce that \( f \) induces an equivalence of \( \infty \)-categories \( 0 \to 0' \). This completes the proof of (b).

It remains to show \( f \) is an approximation to \( 0'^\odot \). According to Remark 2.3.3.19, it will suffice to show that for each \( X \in 0^\odot_{(0)} \), the induced map \( f_X : 0^\odot_{/X} \to 0'^\odot \) is an approximation to \( 0^\odot \). Using Corollary 2.3.3.17, we are reduced to showing that \( f_X \) is a weak approximation to \( 0'^\odot \). We will show that the criterion of Proposition 2.3.4.8 is satisfied. Let \( \mathcal{C}^\odot \) be a symmetric monoidal \( \infty \)-category such that \( \mathcal{C} \) admits small
colimits and the tensor product \( C \times C \rightarrow C \) preserves small colimits separately in each variable, and consider the commutative diagram of forgetful functors \( \sigma : \end{array} \)

\begin{array}{ccc}
\text{Alg}_{O \prime}(C) & \xrightarrow{\theta} & \text{Alg}_{O/X}(C) \\
\downarrow & & \downarrow \\
\text{Fun}(O', C) & \xrightarrow{\theta'} & \text{Fun}(O/X, C),
\end{array}

where the vertical maps have left adjoints \( F_X : \text{Fun}(O/X, C) \rightarrow \text{Alg}_{O/X}(C) \) and \( F' : \text{Fun}(O', C) \rightarrow \text{Alg}_{O}(C) \). We wish to show that the natural transformation \( \alpha : F_X \circ \theta' \rightarrow \theta \circ F' \) is an equivalence. Since \( f \) exhibits \( O' \otimes \) as an assembly of \( O \otimes \), the forgetful functor \( \text{Alg}_{O'}(C) \rightarrow \text{Alg}_O(C) \) is an equivalence. Similarly, \( (b) \) implies that \( \text{Fun}(O', C) \rightarrow \text{Fun}(O, C) \) is an equivalence. We may therefore replace the diagram \( \sigma \) by the equivalent diagram

\begin{array}{ccc}
\text{Alg}_{O}(C) & \xrightarrow{\psi} & \text{Alg}_{O/X}(C) \\
\downarrow & & \downarrow \\
\text{Fun}(O, C) & \xrightarrow{\psi'} & \text{Fun}(O/X, C),
\end{array}

where the left vertical map has a left adjoint \( F : \text{Fun}(O, C) \rightarrow \text{Alg}_O(C) \). We are therefore reduced to proving that the natural transformation \( F_X \circ \psi' \rightarrow \psi \circ F \) is an equivalence, which is a special case of Proposition 2.3.4.9.

\[\square\]

## 2.4 Products and Coproducts

Let \( \mathcal{C} \) be a category which admits finite products. Then the product operation \((X, Y) \mapsto X \times Y\) is commutative and associative (up to canonical isomorphism), and has a unit given by the final object of \( \mathcal{C} \). It follows that the formation of Cartesian products endows \( \mathcal{C} \) with a symmetric monoidal structure, which we will call the \textit{Cartesian symmetric monoidal structure} on \( \mathcal{C} \). Similarly, if \( \mathcal{C} \) admits finite coproducts, then the construction \((X, Y) \mapsto X \coprod Y\) endows \( \mathcal{C} \) with another symmetric monoidal structure, which we call the \textit{coCartesian symmetric monoidal structure}.

Our goal in this section is to study the \( \infty \)-categorical analogues of Cartesian and coCartesian symmetric monoidal structures. To this end, we introduce the following definition:

**Definition 2.4.0.1.** Let \( \mathcal{C} \) be an \( \infty \)-category. We will say that a symmetric monoidal structure on \( \mathcal{C} \) is \textit{Cartesian} if the following conditions are satisfied:

1. The unit object \( 1 \in \mathcal{C} \) is final.
2. For every pair of objects \( C, D \in \mathcal{C} \), the canonical maps
   
   \[ C \simeq C \otimes 1 \leftarrow C \otimes D \rightarrow 1 \otimes D \simeq D \]

   exhibit \( C \otimes D \) as a product of \( C \) and \( D \) in the \( \infty \)-category \( \mathcal{C} \).

Dually, we will say that a symmetric monoidal structure on \( \mathcal{C} \) is \textit{coCartesian} if it satisfies the following pair of analogous conditions:

1. The unit object \( 1 \in \mathcal{C} \) is initial.
2. For every pair of objects \( C, D \in \mathcal{C} \), the canonical maps
   
   \[ C \simeq C \otimes 1 \rightarrow C \otimes D \leftarrow 1 \otimes D \simeq D \]

   exhibit \( C \otimes D \) as a coproduct of \( C \) and \( D \) in the \( \infty \)-category \( \mathcal{C} \).
It is natural to expect that if \( \mathcal{C} \) is an \( \infty \)-category which admits finite products, then the formation of finite products is commutative and associative up to coherent equivalence; that is, \( \mathcal{C} \) should admit a Cartesian symmetric monoidal structure. We will prove this result in \( \S 2.4.1 \) by means of an explicit construction (in fact, this Cartesian symmetric monoidal structure is unique in a strong sense: see Corollary 2.4.1.8). We can then apply to \( \mathcal{C} \) all of the ideas introduced in \( \S 2.1 \); in particular, for any \( \infty \)-operad \( \mathcal{O} \), we can consider the \( \infty \)-category \( \mathcal{C}_{\mathcal{O}}(\mathcal{C}) \) of \( \mathcal{O} \)-algebra objects of \( \mathcal{C} \). Since the Cartesian symmetric monoidal structure on \( \mathcal{C} \) is entirely determined by the structure of the underlying \( \infty \)-category \( \mathcal{C} \), it is natural to expect that \( \mathcal{C}_{\mathcal{O}}(\mathcal{C}) \) admits a direct description which makes no reference to the theory of \( \infty \)-operads. In \( \S 2.4.2 \) we will provide such a description by introducing the notion of a \( 0 \)-monoid. Using this notion, we will characterize the Cartesian symmetric monoidal structure on an \( \infty \)-category \( \mathcal{C} \) by means of a universal mapping property (Proposition 2.4.2.5).

The theory of coCartesian symmetric monoidal structures should be regarded as dual to the theory of Cartesian symmetric monoidal structures: that is, we expect that giving a coCartesian symmetric monoidal structure on an \( \infty \)-category \( \mathcal{C} \) is equivalent to giving a Cartesian symmetric monoidal structure on the \( \infty \)-category \( \mathcal{C}^{op} \). However, this identification is somewhat subtle: our definition of symmetric monoidal \( \infty \)-category is not manifestly self-dual, so it is not immediately obvious that a symmetric monoidal structure on \( \mathcal{C}^{op} \) determines a symmetric monoidal structure on \( \mathcal{C} \) (this is nonetheless true; see Remark 2.4.2.7). Definition 2.0.0.7 encodes a symmetric monoidal structure on an \( \infty \)-category \( \mathcal{C} \) by specifying maps of the form \( X_{1} \otimes \cdots \otimes X_{n} \to Y \); maps of the form \( X \to Y_{1} \otimes \cdots \otimes Y_{n} \) are more difficult to access. For this reason, we devote \( \S 2.4.3 \) to giving an explicit construction of a coCartesian symmetric monoidal structure on an \( \infty \)-category \( \mathcal{C} \) which admits finite coproducts. Roughly speaking, the idea is to specify a symmetric monoidal structure in which giving morphism \( X_{1} \otimes \cdots \otimes X_{n} \to Y \) is equivalent to giving a collection of morphisms \( \{ X_{i} \to Y \}_{1 \leq i \leq n} \). This construction has the advantage of working in great generality: it yields an \( \infty \)-operad \( \mathcal{C}^{1} \) even in cases where the \( \infty \)-category \( \mathcal{C} \) does not admit finite coproducts. We will apply these ideas in \( \S 2.4.4 \) to analyze the tensor product operation on \( \infty \)-operads described in \( \S 2.5 \).

As in the Cartesian case, it is natural to expect that if an \( \infty \)-category \( \mathcal{C} \) is equipped with a coCartesian symmetric monoidal structure, then the theory of algebras in \( \mathcal{C} \) can be formulated without reference to the theory of \( \infty \)-operads. This turns out to be true for a somewhat trivial reason: every object \( C \in \mathcal{C} \) admits a unique commutative algebra structure, with multiplication given by the “fold” map \( C \coprod C \to C \) (Corollary 2.4.3.10). In fact, this can be taken as a characterization of the coCartesian symmetric monoidal structure: we will show that the coCartesian symmetric monoidal structure on \( \mathcal{C} \) is universal among symmetric monoidal \( \infty \)-categories \( \mathcal{D} \) for which there exists a functor \( \mathcal{C} \to C\text{Alg}(\mathcal{D}) \) (Theorem 2.4.3.18).

### 2.4.1 Cartesian Symmetric Monoidal Structures

Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite products. Our main goal in this section is to prove that \( \mathcal{C} \) admits an essentially unique symmetric monoidal structure which is Cartesian in the sense of Definition 2.4.0.1. We begin by describing a useful mechanism for recognizing that a symmetric monoidal structure is Cartesian.

**Definition 2.4.1.1.** Let \( p : \mathcal{C}^{\otimes} \to N(\text{Fin}_{\ast}) \) be an \( \infty \)-operad. A lax Cartesian structure on \( \mathcal{C}^{\otimes} \) is a functor \( \pi : \mathcal{C}^{\otimes} \to \mathcal{D} \) satisfying the following condition:

\( \ast \) Let \( C \) be an object of \( \mathcal{C}^{\otimes}_{(n)} \), and write \( C \simeq C_{1} \oplus \cdots \oplus C_{n} \), where each \( C_{i} \in \mathcal{C} \). Then the canonical maps \( \pi(C) \to \pi(C_{i}) \) exhibit \( \pi(C) \) as a product \( \prod_{1 \leq j \leq n} \pi(C_{j}) \) in the \( \infty \)-category \( \mathcal{D} \).

We will say that \( \pi \) is a weak Cartesian structure if it is a lax Cartesian structure, \( \mathcal{C}^{\otimes} \) is a symmetric monoidal \( \infty \)-category, and the following additional condition is satisfied:

\( \ast' \) Let \( f : C \to C' \) be a \( p \)-coCartesian morphism covering an active morphism \( \alpha : \langle n \rangle \to \langle 1 \rangle \) in \( \text{Fin}_{\ast} \). Then \( \pi(f) \) is an equivalence in \( \mathcal{D} \).

We will say that a weak Cartesian structure \( \pi \) is a Cartesian structure if \( \pi \) restricts to an equivalence \( \mathcal{C} \to \mathcal{D} \).
We define a category $\Gamma^\times$ as follows:

1. An object of $\Gamma^\times$ consists of an ordered pair $(\langle n \rangle, S)$, where $\langle n \rangle$ is an object of $\text{Fin}_\ast$ and $S$ is a subset of $\langle n \rangle^\circ$.
2. A morphism from $(\langle n \rangle, S)$ to $(\langle n' \rangle, S')$ in $\Gamma^\times$ consists of a map $\alpha: \langle n \rangle \to \langle n' \rangle$ in $\text{Fin}_\ast$ with the property that $\alpha^{-1} S' \subseteq S$.

We observe that the forgetful functor $\Gamma^\times \to \text{Fin}_\ast$ has a final object. Then assertions (1) and (2) follow immediately from Corollary T.3.2.2.13, and (3) follows from (2) (since $\Gamma^\times$ is stable under the pushforward functors associated to the coCartesian fibration $p$).

Construction 2.4.1.4. Let $\mathcal{C}$ be an $\infty$-category. We define a simplicial set $\tilde{\mathcal{C}}^\times$ equipped with a map $\tilde{\mathcal{C}}^\times \to N(\text{Fin}_\ast)$ by the following universal property: for every map of simplicial sets $K \to N(\text{Fin}_\ast)$, we have a bijection

$$\text{Hom}_{N(\text{Fin}_\ast)}(K, \tilde{\mathcal{C}}^\times) \simeq \text{Hom}_{\text{Set}_\Delta}(K \times_{N(\text{Fin}_\ast)} N(\Gamma^\times), \mathcal{C}).$$

Fix $\langle n \rangle \in \text{Fin}_\ast$. We observe that the fiber $\tilde{\mathcal{C}}^\times_{\langle n \rangle}$ can be identified with the $\infty$-category of functors $f: N(P)^{op} \to \mathcal{C}$, where $P$ is the partially ordered set of subsets of $\langle n \rangle^\circ$. We let $\mathcal{C}^\times$ be the full simplicial subset of $\tilde{\mathcal{C}}^\times$ spanned by those vertices which correspond to those functors $f$ with the property that for every $S \subseteq \langle n \rangle^\circ$, the maps $f(S) \to f(\{j\})$ exhibit $f(S)$ as a product of the objects $\{f(\{j\})\}_{j \in S}$ in the $\infty$-category $\mathcal{C}$.

The fundamental properties of Construction 2.4.1.4 are summarized in the following result:

Proposition 2.4.1.5. Let $\mathcal{C}$ be an $\infty$-category.

1. The projection $p: \tilde{\mathcal{C}}^\times \to N(\text{Fin}_\ast)$ is a coCartesian fibration.
2. Let $\overline{\alpha}: f \to f'$ be a morphism of $\tilde{\mathcal{C}}^\times$ whose image in $N(\text{Fin}_\ast)$ corresponds to a map $\alpha: \langle n \rangle \to \langle n' \rangle$. Then $\overline{\alpha}$ is $p$-coCartesian if and only if, for every $S \subseteq \langle n' \rangle^\circ$, the induced map $f(\alpha^{-1} S) \to f'(S)$ is an equivalence in $\mathcal{C}$.
3. The projection $p$ restricts to a coCartesian fibration $\mathcal{C}^\times \to N(\text{Fin}_\ast)$ (with the same class of coCartesian morphisms).
4. The projection $\mathcal{C}^\times \to N(\text{Fin}_\ast)$ is a symmetric monoidal $\infty$-category if and only if $\mathcal{C}$ admits finite products.
5. Suppose that $\mathcal{C}$ admits finite products. Let $\pi: \mathcal{C}^\times \to \mathcal{C}$ be the map given by composition with the section $s: N(\text{Fin}_\ast) \to N(\Gamma^\times)$ defined in Remark 2.4.1.3. Then $\pi$ is a Cartesian structure on $\mathcal{C}^\times$.

Proof: Assertions (1) and (2) follow immediately from Corollary T.3.2.2.13, and (3) follows from (2) (since $\mathcal{C}^\times$ is stable under the pushforward functors associated to the coCartesian fibration $p$). We now prove (4). If $\mathcal{C}$ has no final object, then $\mathcal{C}^\times_{\langle 0 \rangle}$ is empty; consequently, we may assume without loss of generality that $\mathcal{C}$ has a final object. Then $\mathcal{C}^\times_{\langle 1 \rangle}$ is isomorphic to the $\infty$-category of diagrams $X \to Y$ in $\mathcal{C}$, where $Y$ is final. It follows that $\pi$ induces an equivalence $\mathcal{C}^\times_{\langle 1 \rangle} \simeq \mathcal{C}$. Consequently, $\mathcal{C}^\times$ is a symmetric monoidal $\infty$-category.
If and only if, for each \( n \geq 0 \), the functors \( p_j^l \) determine an equivalence \( \phi : \mathcal{E}^\times_{(n)} \to \mathcal{E}^n \). Let \( P \) denote the partially ordered set of subsets of \( \{n\}^\times \), and let \( P_0 \subseteq P \) be the partially ordered set consisting of subsets which consist of a single element. Then \( \mathcal{E}^\times_{(n)} \) can be identified with the set of functors \( f : N(P_0)^{op} \to \mathcal{E} \) which are right Kan extensions of \( f | N(P_0)^{op} \), and \( \phi \) can be identified with the restriction map determined by the inclusion \( P_0 \subseteq P \). According to Proposition \( T.4.3.2.15 \), \( \phi \) is fully faithful, and is essentially surjective if and only if every functor \( f_0 : N(P_0)^{op} \to \mathcal{E} \) admits a right Kan extension to \( N(P)^{op} \). Unwinding the definitions, we see that this is equivalent to the assertion that every finite collection of objects of \( \mathcal{E} \) admits a product in \( \mathcal{E} \). This completes the proof of (4). Assertion (5) follows immediately from (2) and the construction of \( \mathcal{E}^\times \).

It follows from Proposition \( 2.4.1.5 \) that if \( \mathcal{E} \) is an \( \infty \)-category which admits finite products, then \( \mathcal{E} \) admits a Cartesian symmetric monoidal structure. Our next goal is to show that this Cartesian symmetric monoidal structure is unique up to equivalence. In other words, we claim that if \( \mathcal{E}^\otimes \) is any Cartesian symmetric monoidal \( \infty \)-category, then there exists a symmetric monoidal equivalence \( \mathcal{E}^\otimes \simeq \mathcal{E}^\times \) (extending the identity functor on \( \mathcal{E} \)). The proof will proceed in two steps:

1. We will show that \( \mathcal{E}^\otimes \) admits a Cartesian structure \( \pi' : \mathcal{E}^\otimes \to \mathcal{E} \).

2. We will show that any Cartesian structure \( \pi' : \mathcal{E}^\otimes \to \mathcal{E} \) is homotopic to a composition \( \mathcal{E}^\otimes \xrightarrow{F} \mathcal{E}^\times \xrightarrow{\pi} \mathcal{E} \), where \( \pi \) is the Cartesian structure appearing in Proposition \( 2.4.1.5 \) and \( F \) is a symmetric monoidal functor (automatically an equivalence).

More precisely, we have the following pair of results, whose proofs will be given at the end of this section:

**Proposition 2.4.1.6.** Let \( p : \mathcal{E}^\otimes \to N(\text{Fin}_*) \) be a Cartesian symmetric monoidal \( \infty \)-category and let \( \mathcal{D} \) be another \( \infty \)-category which admits finite products. Let \( \text{Fun}^\times (\mathcal{E}^\otimes, \mathcal{D}) \) denote the full subcategory of \( \text{Fun}(\mathcal{E}^\otimes, \mathcal{D}) \) spanned by the weak Cartesian structures, and let \( \text{Fun}^\times (\mathcal{E}, \mathcal{D}) \) be the full subcategory of \( \text{Fun}(\mathcal{E}, \mathcal{D}) \) spanned by those functors which preserve finite products. The restriction map \( \text{Fun}^\times (\mathcal{E}^\otimes, \mathcal{D}) \to \text{Fun}^\times (\mathcal{E}, \mathcal{D}) \) is an equivalence of \( \infty \)-categories.

**Proposition 2.4.1.7.** Let \( \mathcal{O}^\otimes \) be an \( \infty \)-operad, \( \mathcal{D} \) an \( \infty \)-category which admits finite products, and \( \pi : \mathcal{D}^\times \to \mathcal{D} \) the Cartesian structure of Proposition \( 2.4.1.5 \). Then composition with \( \pi \) induces a trivial Kan fibration

\[
\theta : \text{Alg}_{\mathcal{D}}(\mathcal{D}) \to \text{Fun}^\text{lax}(\mathcal{O}^\otimes, \mathcal{D})
\]

where \( \text{Fun}^\text{lax}(\mathcal{O}^\otimes, \mathcal{D}) \) denotes the full subcategory of \( \text{Fun}(\mathcal{O}^\otimes, \mathcal{D}) \) spanned by the lax Cartesian structures. If \( \mathcal{O}^\otimes \) is a symmetric monoidal \( \infty \)-category, then composition with \( \pi \) induces a trivial Kan fibration

\[
\theta_0 : \text{Fun}^\times (\mathcal{O}^\otimes, \mathcal{D}^\times) \to \text{Fun}^\times (\mathcal{O}^\otimes, \mathcal{D})
\]

where \( \text{Fun}^\times (\mathcal{O}^\otimes, \mathcal{D}) \) denotes the full subcategory of \( \text{Fun}(\mathcal{O}^\otimes, \mathcal{D}) \) spanned by the weak Cartesian structures.

Combining these results, we obtain the following:

**Corollary 2.4.1.8.** Let \( \mathcal{E}^\otimes \) be a Cartesian symmetric monoidal \( \infty \)-category whose underlying \( \infty \)-category \( \mathcal{E} \) admits finite products, and let \( \mathcal{D} \) be an \( \infty \)-category which admits finite products. Then:

1. The restriction functor \( \theta : \text{Fun}^\times (\mathcal{E}^\otimes, \mathcal{D}^\times) \to \text{Fun}(\mathcal{E}, \mathcal{D}) \) is fully faithful.

2. The essential image of \( \theta \) is the full subcategory \( \text{Fun}^\times (\mathcal{E}, \mathcal{D}) \) spanned by those functors which preserve finite products.

3. There exists a symmetric monoidal equivalence \( \mathcal{E}^\otimes \simeq \mathcal{E}^\times \) whose restriction to the underlying \( \infty \)-category \( \mathcal{E} \) is homotopic to the identity.
2.4. PRODUCTS AND COPRODUCTS

Proof. To prove assertions (1) and (2), we note that \( \theta \) factors as a composition

\[
\Fun_{\infty}(\mathcal{C}, \mathcal{D}) \xrightarrow{\theta'} \Fun_{\infty}(\mathcal{E}, \mathcal{D}) \xrightarrow{\theta''} \Fun_{\infty}(\mathcal{E}, \mathcal{D}),
\]

where \( \theta' \) is the trivial Kan fibration of Proposition 2.4.1.7 and \( \theta'' \) is the equivalence of \( \infty \)-categories of Proposition 2.4.1.6. Taking \( \mathcal{C} = \mathcal{D} \), we deduce the existence of a symmetric monoidal functor \( F : \mathcal{C}^\otimes \to \mathcal{C}^\times \) which is homotopic to the identity on \( \mathcal{C} \). It follows from Remark 2.1.3.8 that \( F \) is an equivalence of symmetric monoidal \( \infty \)-categories.

Using Corollary 2.4.1.8, we can formulate an even stronger uniqueness claim for Cartesian symmetric monoidal structures. Let \( \Cat_{\infty}^\otimes \) be the \( \infty \)-category of symmetric monoidal \( \infty \)-categories (see Variation 2.4.1.13), and let \( \Cat_{\infty}^\otimes, \times \subseteq \Cat_{\infty}^\otimes \) be the full subcategory spanned by the Cartesian symmetric monoidal \( \infty \)-categories. Let \( \Cat_{\infty}^\Cart \subseteq \Cat_{\infty} \) denote the subcategory spanned by those \( \infty \)-categories \( \mathcal{C} \) which admit finite products, and those functors which preserve finite products. Then:

**Corollary 2.4.1.9.** The forgetful functor \( \theta : \Cat_{\infty}^\otimes, \times \to \Cat_{\infty}^\Cart \) is an equivalence of \( \infty \)-categories.

**Proof.** It follows from Proposition 2.4.1.5 that the functor \( \theta \) is essentially surjective. To prove that \( \theta \) is fully faithful, let us suppose that we are given a pair of Cartesian symmetric monoidal \( \infty \)-categories \( \mathcal{C}^\otimes \) and \( \mathcal{D}^\otimes \); we wish to show that the map

\[
\Map_{\Cat_{\infty}^\otimes}(\mathcal{C}^\otimes, \mathcal{D}^\otimes) \to \Map_{\Cat_{\infty}^\Cart}(\mathcal{C}, \mathcal{D})
\]

is a homotopy equivalence of Kan complexes. This follows immediately from Corollary 2.4.1.8. \( \square \)

**Example 2.4.1.10.** Let \( \mathbf{A} \) be a simplicial model category. Suppose that the Cartesian monoidal structure on \( \mathbf{A} \) is compatible with the model structure (in other words, that the final object of \( \mathbf{A} \) is cofibrant, and that for any pair of cofibrations \( i : A \to A', j : B \to B' \), the induced map \( i \wedge j : (A \times B') \coprod_{A \times B} (A' \times B) \to A' \times B' \) is a cofibration, trivial if either \( i \) or \( j \) is trivial). Since the collection of fibrant-cofibrant objects of \( \mathbf{A} \) is stable under finite products, the construction \( \{A_i\}_{1 \leq i \leq n} \mapsto \coprod A_i \) determines a functor \( \pi : N(\mathbf{A}^\otimes) \to N(\mathbf{A}^\infty) \), where \( N(\mathbf{A}^\infty) \) is the \( \infty \)-operad of Proposition 4.1.3.10. It is not difficult to see that \( \pi \) is a Cartesian structure on \( N(\mathbf{A}^\infty) \) which determines a Cartesian symmetric monoidal structure on \( N(\mathbf{A}^\infty) \) which coincides with the symmetric monoidal structure given by Proposition 4.1.3.10.

We conclude this section by giving proofs of Propositions 2.4.1.6 and 2.4.1.7.

**Proof of Proposition 2.4.1.6.** We define a subcategory \( \mathcal{J} \subseteq \text{Fin}_* \times [1] \) as follows:

1. Every object of \( \text{Fin}_* \times [1] \) belongs to \( \mathcal{J} \).
2. A morphism \( \langle \langle n \rangle, i \rangle \to \langle \langle n' \rangle, i' \rangle \) in \( \text{Fin}_* \times [1] \) belongs to \( \mathcal{J} \) if and only if either \( i' = 1 \) or the induced map \( \alpha : \langle n \rangle \to \langle n' \rangle \) satisfies \( \alpha^{-1} \{*\} = \{1\} \).

Let \( \mathcal{C}' \) denote the fiber product \( \mathcal{C}^\otimes \times_{N(\text{Fin}_*)} N(\mathcal{J}) \), which we regard as a subcategory of \( \mathcal{C}^\otimes \times \Delta^1 \), and let \( p' : \mathcal{C}' \to N(\mathcal{J}) \) denote the projection. Let \( \mathcal{C}'_0 \) and \( \mathcal{C}'_1 \) denote the intersections of \( \mathcal{C}' \) with \( \mathcal{C}^\otimes \times \{0\} \) and \( \mathcal{C}^\otimes \times \{1\} \), respectively. We note that there is a canonical isomorphism \( \mathcal{C}'_1 \simeq \mathcal{C}^\otimes \).

Let \( \mathcal{E} \) denote the full subcategory of \( \text{Fun}(\mathcal{C}', \mathcal{D}) \) spanned by those functors \( F \) which satisfy the following conditions:

1. For every object \( C \in \mathcal{C}^\otimes \), the induced map \( F(C, 0) \to F(C, 1) \) is an equivalence in \( \mathcal{D} \).
2. The restriction \( F|_{\mathcal{C}'_1} \) is a weak Cartesian structure on \( \mathcal{C}^\otimes \).

It is clear that if (i) and (ii) are satisfied, then the restriction \( F_0 = F|_{\mathcal{C}'_0} \) satisfies the following additional conditions:
(iii) The restriction $F_0|\mathcal{C}_0^\otimes \times \{0\}$ is a functor from $\mathcal{C}$ to $\mathcal{D}$ which preserves finite products.

(iv) For every $p'$-coCartesian morphism $\alpha$ in $\mathcal{C}_0'$, the induced map $F_0(\alpha)$ is an equivalence in $\mathcal{D}$.

Moreover, (i) is equivalent to the assertion that $F$ is a right Kan extension of $F|\mathcal{C}_1'$. Proposition T.4.3.2.15 implies that the restriction map $r: \mathcal{E} \to \text{Fun}^\times(\mathcal{C}_0^\otimes, \mathcal{D})$ induces a trivial Kan fibration onto its essential image. The map $r$ has a section $s$, given by composition with the projection map $\mathcal{E}' \to \mathcal{C}_0^\otimes$. The restriction map $\text{Fun}^\times(\mathcal{C}_0^\otimes, \mathcal{D}) \to \text{Fun}^\times(\mathcal{C}, \mathcal{D})$ factors as a composition

$$\text{Fun}^\times(\mathcal{C}_0^\otimes, \mathcal{D}) \xrightarrow{r} \mathcal{E} \xrightarrow{s} \text{Fun}^\times(\mathcal{C}, \mathcal{D}),$$

where $e$ is induced by composition with the inclusion $\mathcal{C} \subseteq \mathcal{C}_0' \subseteq \mathcal{C}'$. Consequently, it will suffice to prove that $e$ is an equivalence of $\infty$-categories.

Let $\mathcal{E}_0 \subseteq \text{Fun}(\mathcal{C}_0', \mathcal{D})$ be the full subcategory spanned by those functors which satisfy conditions (iii) and (iv). The map $e$ factors as a composition

$$\mathcal{E} \xrightarrow{e'} \mathcal{E}_0 \xrightarrow{e''} \text{Fun}^\times(\mathcal{C}, \mathcal{D}).$$

Consequently, it will suffice to show that $e'$ and $e''$ are trivial Kan fibrations.

Let $f: \mathcal{C}_0' \to \mathcal{D}$ be an arbitrary functor, and let $C \in \mathcal{C}_0^\otimes \subseteq \mathcal{C}_0'$. There exists a unique map $\alpha: (\{n\}, 0) \to (\{1\}, 0)$ in $\mathcal{J}$; choose a $p'$-coCartesian morphism $\overline{\alpha}: C \to C'$ lifting $\alpha$. We observe that $C'$ is an initial object of $\mathcal{E} \times (\mathcal{C}_0')/C \times \mathcal{E}_0' \subseteq \mathcal{C}_0'$. Consequently, $f$ is a right Kan extension of $f|\mathcal{C}$ at $C$ if and only if $f(\overline{\alpha})$ is an equivalence. It follows that $f$ satisfies (iv) if and only if $f$ is a right Kan extension of $f|\mathcal{C}$. The same argument (and Lemma T.4.3.2.7) shows that every functor $f_0: \mathcal{C} \to \mathcal{D}$ admits a right Kan extension to $\mathcal{C}_0'$. Applying Proposition T.4.3.2.15, we deduce that $e''$ is a trivial Kan fibration.

It remains to show that $e'$ is a trivial Kan fibration. In view of Proposition T.4.3.2.15, it will suffice to prove the following pair of assertions, for every functor $f \in \mathcal{E}_0$:

1. There exist a functor $F: \mathcal{C}' \to \mathcal{D}$ which is a left Kan extension of $f = F|\mathcal{C}_0'$.
2. An arbitrary functor $F: \mathcal{C}' \to \mathcal{D}$ which extends $f$ is a left Kan extension of $f$ if and only if $F$ belongs to $\mathcal{E}$.

For every finite linearly ordered set $J$, let $J^+$ denote the disjoint union $J \coprod \{\infty\}$, where $\infty$ is a new element larger than every element of $J$. Let $(C, 1) \in \mathcal{C}_0^\otimes \times \{1\} \subseteq \mathcal{C}$.

Since there exists a final object $1_e \in \mathcal{C}$, the $\infty$-category $\mathcal{C}_0' \times_{\mathcal{C}} \mathcal{C}_0'^1$ also has a final object, given by the map $\alpha: (C', 0) \to (C, 1)$, where $C' \in \mathcal{C}_0^\otimes$ corresponds, under the equivalence

$$\mathcal{C}_0^\otimes_{J^+} \simeq \mathcal{C} \times \mathcal{C}_0^\otimes_{J^+},$$

to the pair $(1_e, C)$. We now apply Lemma T.4.3.2.13 to deduce (1), together with the following analogue of (2):

(2') An arbitrary functor $F: \mathcal{C}' \to \mathcal{D}$ which extends $f$ is a left Kan extension of $f$ if and only if, for every morphism $\alpha: (C', 0) \to (C, 1)$ as above, the induced map $F(C', 0) \to F(C, 1)$ is an equivalence in $\mathcal{D}$.

To complete the proof, it will suffice to show that $F$ satisfies the conditions stated in (2') if and only if $F \in \mathcal{E}$. We first prove the “if” direction. Let $\alpha: (C', 0) \to (C, 1)$ be as above; we wish to prove that $F(\alpha): F(C', 0) \to F(C, 1)$ is an equivalence in $\mathcal{D}$. The map $\alpha$ factors as a composition

$$(C', 0) \xrightarrow{\alpha'} (C', 1) \xrightarrow{\alpha''} (C, 1).$$

Condition (i) guarantees that $F(\alpha')$ is an equivalence. Condition (ii) guarantees that $F(C', 1)$ is equivalent to a product $F(1_e, 1) \times F(C, 1)$, and that $F(\alpha'')$ can be identified with the projection onto the second factor.
Moreover, since $1_C$ is a final object of \mathcal{C}, condition (ii) also guarantees that $F(1_C, 1)$ is a final object of \mathcal{D}. It follows that $F(\alpha'')$ is an equivalence, so that $F(\alpha)$ is an equivalence as desired.

Now let us suppose that $F$ satisfies the condition stated in (2'). We wish to prove that $F \in \mathcal{E}$. Here we must invoke our assumption that the monoidal structure on \mathcal{E} is Cartesian. We begin by verifying condition (i). Let $C \in \mathcal{E}^\otimes_{\mathcal{J}_1}$ for some finite linearly ordered set $J$, and let $\alpha : (C', 0) \rightarrow (C, 1)$ be defined as above. Let $\beta : (J_+, 0) \rightarrow (J^+_+, 0)$ be the morphism in \mathcal{J} induced by the inclusion $J \subseteq J^+$. Choose a $p'$-coCartesian morphism $\beta : (C, 0) \rightarrow (C'', 0)$ lifting $\beta$. Since the final object $1_C \in \mathcal{E}$ is also the unit object of \mathcal{C}, we can identify $C''$ with $C'$. The composition $(C, 0) \xrightarrow{\gamma} (C', 1) \xrightarrow{\gamma} (C, 1)$ is homotopic to the canonical map $\gamma : (C, 0) \rightarrow (C, 1)$ appearing in the statement of (i). Condition (iv) guarantees that $F(\beta)$ is an equivalence, and (2') guarantees that $F(\alpha)$ is an equivalence. Using the two-out-of-three property, we deduce that $F(\gamma)$ is an equivalence, so that $F$ satisfies (i).

To prove that $F$ satisfies (ii), we must verify two conditions:

(iii) If $\beta : (C, 1) \rightarrow (D, 1)$ is a $p'$-coCartesian morphism in \mathcal{C}', and the underlying morphism $\beta : \langle m \rangle \rightarrow \langle n \rangle$ satisfies $\beta^{-1}\{*\} = \{*\}$, then $F(\beta)$ is an equivalence.

Let $C \in \mathcal{E}^\otimes_{\langle n \rangle}$, and choose $p$-coCartesian morphisms $\gamma_i : C \rightarrow C_j$ covering the maps $\rho^i : \langle n \rangle \rightarrow \langle 1 \rangle$.

Then the maps $\gamma_i$ exhibit $F(C, 1)$ as a product $\prod_{1 \leq j \leq n} F(C_j, 1)$ in the \infty-category \mathcal{D}.

Condition (2') guarantees that the maps $F(\alpha)$ and $F(\alpha_i)$ are equivalences in \mathcal{D}. Consequently, it will suffice to show that the maps $f(\gamma'_i)$ exhibit $f(C', 0)$ as a product $\prod_{j \in J} f(C'_j, 0)$ in \mathcal{D}. Let $f_0 = f|\mathcal{C}$. Using condition (iv), we obtain canonical equivalences

$$f(C', 0) \simeq f_0(1_C \otimes \bigotimes_{j \in J} C_j) \quad \text{and} \quad f(C''_j, 0) \simeq f_0(1_C \otimes C_j)$$

Since condition (iii) guarantees that $f_0$ preserves products, it will suffice to show that the canonical map

$$1_C \otimes (\bigotimes_{1 \leq j \leq n} C_j) \rightarrow \bigotimes_{1 \leq j \leq n} (1_C \otimes C_j)$$

is an equivalence in the \infty-category \mathcal{C}. This follows easily from our assumption that the symmetric monoidal structure on \mathcal{C} is Cartesian, using induction on $n$.

Proof of Proposition 2.4.1.7. Unwinding the definitions, we can identify $\text{Alg}_{\mathcal{D}}(\mathcal{D})$ with the full subcategory of $\text{Fun}(\mathcal{O}^\otimes \times_{\mathcal{N}(\mathcal{J}_{\text{fin}})} \mathcal{N}(\mathcal{I}^\times), \mathcal{D})$ spanned by those functors $F$ which satisfy the following conditions:

1. For every object $C \in \mathcal{O}^\otimes$ and every subset $S \subseteq \langle n \rangle^\circ$, the functor $F$ induces an equivalence

$$F(C, S) \rightarrow \prod_{j \in S} F(C, \{j\})$$

in the \infty-category \mathcal{D}.

2. For every inert morphism $C \rightarrow C'$ in $\mathcal{O}^\otimes$ which covers $\langle n \rangle \rightarrow \langle n' \rangle$ and every subset $S \subseteq \langle n' \rangle^\circ$, the induced map $F(C, \alpha^{-1} S) \rightarrow F(C', S)$ is an equivalence in \mathcal{D}. 

\[\square\]
The functor $F' = \pi \circ F$ can be described by the formula $F'(C) = F(C, \langle n \rangle^\circ)$, for each $C \in \mathcal{O}^\circ$. In other words, $F'$ can be identified with the restriction of $F$ to the full subcategory $\mathcal{C} \subseteq \mathcal{O}^\circ \times_{\mathcal{N}(\mathcal{F}in_\ast)} \mathcal{N}(\Gamma^\times)$ spanned by objects of the form $(C, \langle n \rangle^\circ)$.

Let $X = (C, S)$ be an object of the fiber product $\mathcal{O}^\circ \times_{\mathcal{N}(\mathcal{F}in_\ast)} \mathcal{N}(\Gamma^\times)$. Here $C \in \mathcal{O}^\circ_{(n)}$, and $S \subseteq \langle n \rangle^\circ$. We claim that the $\infty$-category $\mathcal{C}_X$ has an initial object. More precisely, if we choose a $p$-coCartesian morphism $\alpha : C \to C'$ covering the map $\alpha : \langle n \rangle \to S_*$ given by the formula

$$\alpha(j) = \begin{cases} j & \text{if } j \in S \\ * & \text{otherwise,} \end{cases}$$

then the induced map $\bar{\alpha} : (C, S) \to (C', S)$ is an initial object of $\mathcal{C}_X$. It follows that every functor $F' : \mathcal{C} \to \mathcal{D}$ admits a right Kan extension to $\mathcal{O}^\circ \times_{\mathcal{N}(\mathcal{F}in_\ast)} \mathcal{N}(\Gamma^\times)$, and that an arbitrary functor $F : \mathcal{O}^\circ \times_{\mathcal{N}(\mathcal{F}in_\ast)} \mathcal{N}(\Gamma^\times) \to \mathcal{D}$ is a right Kan extension of $F|\mathcal{C}$ if and only if $F(\bar{\alpha})$ is an equivalence, for every $\bar{\alpha}$ defined as above.

Let $\mathcal{E}$ be the full subcategory of $\text{Fun}(\mathcal{O}^\circ \times_{\mathcal{N}(\mathcal{F}in_\ast)} \mathcal{N}(\Gamma^\times), \mathcal{D})$ spanned by those functors $F$ which satisfy the following conditions:

1. The restriction $F' = F|\mathcal{C}$ is a lax Cartesian structure on $\mathcal{O}^\circ \simeq \mathcal{C}$.
2. The functor $F$ is a right Kan extension of $F'$.

Using Proposition T.4.3.2.15, we conclude that the restriction map $\mathcal{E} \to \text{Fun}^{lax}(\mathcal{O}^\circ, \mathcal{D})$ is a trivial fibration of simplicial sets. To prove that $\theta$ is a trivial Kan fibration, it will suffice to show that conditions (1) and (2) are equivalent to conditions (1') and (2').

Suppose first that (1') and (2') are satisfied by a functor $F$. Condition then (1) follows easily; we will prove (2). Choose a map $C \to C'$ covering a inert morphism $\langle n \rangle \to \langle n' \rangle$ in $\mathcal{F}in_\ast$, and let $S \subseteq \langle n' \rangle^\circ$. Define another inert morphism $\alpha : \langle n' \rangle \to S_*$ by the formula

$$\alpha(j) = \begin{cases} j & \text{if } j \in S \\ * & \text{otherwise,} \end{cases}$$

and choose a $p$-coCartesian morphism $C' \to C''$ lifting $\alpha$. Condition (2') implies that the maps $F(C, \alpha^{-1}S) \to F(C'', S)$ and $F(C', S) \to F(C'', S)$ are equivalences in $\mathcal{D}$. Using the two-out-of-three property, we deduce that the map $F(C, \alpha^{-1}S) \to F(C', S)$ is likewise an equivalence in $\mathcal{D}$. This proves (2).

Now suppose that (1) and (2) are satisfied by $F$. The implication (2) $\Rightarrow$ (2') is obvious; it will therefore suffice to verify (1'). Let $C$ be an object of $\mathcal{O}^\circ_{(n)}$, and choose $p$-coCartesian morphisms $g_j : C \to C_j$ covering the inert morphisms $\rho^j : \langle n \rangle \to \langle 1 \rangle$ for $1 \leq j \leq n$. We wish to show that the induced map $F(C, \langle n \rangle^\circ) \to \prod_{1 \leq j \leq n} F(C_j, \langle 1 \rangle^\circ)$ is an equivalence in $\mathcal{D}$, which follows immediately from (1) and (2'). This completes the proof that $\theta$ is a trivial Kan fibration.

Now suppose that $\mathcal{O}^\circ$ is a symmetric monoidal $\infty$-category. To prove that $\theta_0$ is a trivial Kan fibration, it will suffice to show that $\theta_0$ is a pullback of $\theta$. In other words, it will suffice to show that if $F : \mathcal{O}^\circ \times_{\mathcal{N}(\mathcal{F}in_\ast)} \mathcal{N}(\Gamma^\times) \to \mathcal{D}$ is a functor satisfying conditions (1) and (2), then $F|\mathcal{C}$ is a weak Cartesian structure on $\mathcal{O}^\circ \simeq \mathcal{C}$ if and only if $F$ determines a symmetric monoidal functor from $\mathcal{O}^\circ$ into $\mathcal{D}^\times$. Let $q : \mathcal{D}^\times \to \mathcal{N}(\mathcal{F}in_\ast)$ denote the projection. Using the description of the class of $q$-coCartesian morphisms provided by Proposition 2.4.1.5, we see that the latter condition is equivalent to

1. For every $p$-coCartesian morphism $\bar{\alpha} : C \to C'$ in $\mathcal{O}^\circ$ covering a map $\alpha : \langle n \rangle \to \langle n' \rangle$ in $\mathcal{F}in_\ast$, and every $S \subseteq \langle n' \rangle^\circ$, the induced map $F(C, \alpha^{-1}(S)) \to F(C, S)$ is an equivalence in $\mathcal{D}$.

Moreover, $F|\mathcal{C}$ is a weak Cartesian structure if and only if $F$ satisfies the following:

1. For each $n \geq 0$ and every $p$-coCartesian morphism $\bar{\beta} : C \to C'$ in $\mathcal{O}^\circ$ lifting the map $\beta : \langle n \rangle \to \langle 1 \rangle$ such that $\beta^{-1}\{\ast\} = \{\ast\}$, the induced map $F(C, \langle n \rangle^\circ) \to F(C', \langle 1 \rangle^\circ)$ is an equivalence in $\mathcal{D}$.
It is clear that (a) implies (b). Conversely, suppose that (b) is satisfied, and let \( \tau \) and \( S \subseteq \langle n \rangle^0 \) be as in the statement of (a). Choose \( p \)-coCartesian morphisms \( \tau : C \to C_0 \), \( \tau' : C' \to C'_0 \), \( \beta : C'_0 \to C''_0 \) covering the maps \( \gamma : \langle n \rangle \to \langle \alpha^{-1} S \rangle, \gamma' : \langle n' \rangle \to S, \beta : \langle n' \rangle \to \langle 1 \rangle \) described by the formulas

\[
\beta(j) = \begin{cases} 1 & \text{if } j \in S, \\ * & \text{if } j = * \end{cases}
\]

\[
\gamma(j) = \begin{cases} j & \text{if } j \in \alpha^{-1} S, \\ * & \text{otherwise} \end{cases}
\]

\[
\gamma'(j) = \begin{cases} 1 & \text{if } j \in S, \\ * & \text{otherwise.} \end{cases}
\]

We have a commutative diagram

\[
\begin{array}{ccc}
F(C, \alpha^{-1} S) & \longrightarrow & F(C', S) \\
\downarrow & & \downarrow \\
F(C_0, \alpha^{-1} S) & \xrightarrow{g} & F(C'_0, S) \xrightarrow{g'} F(C''_0, \{0\})
\end{array}
\]

Condition (b) implies that \( g' \) and \( g' \circ g \) are equivalences, so that \( g \) is an equivalence by the two-out-of-three property. Condition (2') implies that the vertical maps are equivalences, so that the upper horizontal map is also an equivalence, as desired.

### 2.4.2 Monoid Objects

At the beginning of this chapter, we reviewed the notion of a commutative monoid: that is, a set \( M \) equipped with a multiplication \( M \times M \to M \) which is commutative, associative and unital. If \( \mathcal{C} \) is a category which admits finite products, one can consider commutative monoids in \( \mathcal{C} \): that is, objects \( M \in \mathcal{C} \) equipped with unit and multiplication maps

\[
* : M \quad M \times M \to M
\]

satisfying the usual axioms, where \( * \) denotes a final object of \( \mathcal{C} \). In this section, we would like to generalize still further: if \( \mathcal{C} \) is an \( \infty \)-category which admits finite products, then we should be able to define a new \( \infty \)-category \( \text{Mon}_{\text{Comm}}(\mathcal{C}) \) of commutative monoid objects of \( \mathcal{C} \). Our definition will have the following features:

(a) If \( \mathcal{C} = \text{Cat}_{\infty} \) is the \( \infty \)-category of (small) \( \infty \)-categories, then a commutative monoid object of \( \mathcal{C} \) is essentially the same thing as a symmetric monoidal \( \infty \)-category (in the sense of Definition 2.0.0.7).

(b) If we regard \( \mathcal{C} \) as endowed with the Cartesian symmetric monoidal structure of §2.4.1, we have a canonical equivalence \( \text{Mon}_{\text{Comm}}(\mathcal{C}) \simeq \text{Alg}_{\text{Comm}}(\mathcal{C}) \).

In fact, (b) suggests that for any \( \infty \)-operad \( O^\otimes \), we can define an \( \infty \)-category \( \text{Mon}_O(\mathcal{C}) \) by the formula

\[
\text{Mon}_O(\mathcal{C}) = \text{Alg}_O(\mathcal{C}),
\]

where \( \mathcal{C} \) is endowed with the Cartesian symmetric monoidal structure. However, for many purposes it is convenient to have a more direct description of \( \text{Mon}_O(\mathcal{C}) \) which does not make use of the theory of \( \infty \)-operads. We instead take our cue from (a). According to Definition 2.0.0.7, a symmetric monoidal \( \infty \)-category is a coCartesian fibration \( \mathcal{C}^\otimes \to \text{Comm}^\otimes \) satisfying certain conditions. Such a fibration is classified by a map \( \chi : \text{Comm}^\otimes \to \text{Cat}_{\infty} \). This suggests the following definition:

**Definition 2.4.2.1.** Let \( \mathcal{C} \) be an \( \infty \)-category and let \( O^\otimes \) be an \( \infty \)-operad. A \( O \)-monoid in \( \mathcal{C} \) is a functor \( M : O^\otimes \to \mathcal{C} \) with the following property: for every object \( X \in O^\otimes_{\langle n \rangle} \) corresponding to a sequence of objects \( \{X_i \in O\}_{1 \leq i \leq n} \), the canonical maps \( M(X) \to M(X_i) \) exhibit \( M(X) \) as a product \( \prod_{1 \leq i \leq n} M(X_i) \) in the \( \infty \)-category \( \mathcal{C} \). We let \( \text{Mon}_O(\mathcal{C}) \) denote the full subcategory of \( \text{Fun}(O^\otimes, \mathcal{C}) \) spanned by the \( O \)-monoids in \( \mathcal{C} \).
Remark 2.4.2.2. In the special case where $\mathcal{O}^\otimes$ is the commutative $\infty$-operad, we will refer to $\mathcal{O}$-monoids in an $\infty$-category $\mathcal{C}$ as commutative monoid objects of $\mathcal{C}$. These objects might also be referred to as $\Gamma$-objects of $\mathcal{C}$; in the special case where $\mathcal{C}$ is the $\infty$-category of spaces, the theory of $\Gamma$ objects is essentially equivalent to Segal’s theory of $\Gamma$-spaces.

Remark 2.4.2.3. Let $\mathcal{C}$ be an $\infty$-category and let $F : \text{Comm}^\otimes \simeq N(\text{Fin}_*) \to \mathcal{C}$ be a commutative monoid object of $\mathcal{C}$. It follows from Definition 2.4.2.1 that for each $n \geq 0$, the object $F((n)) \in \mathcal{C}$ can be identified with the $n$-fold product of $M = F((1))$ with itself. The unique active morphism $\langle n \rangle \to \langle 1 \rangle$ then corresponds to a map $M^n \to M$. In particular, taking $n = 2$, we get a multiplication map $m : M \times M \simeq F((2)) \to F((1)) \simeq M$ in $\mathcal{C}$. It is not difficult to see that the multiplication $m$ is commutative and associative up to homotopy; in fact, the existence of the functor $F$ is an expression of the idea that $m$ is commutative, associative, and unital, up to coherent homotopy.

The construction $F \mapsto M = F((1))$ determines a forgetful functor $\text{Mono}_{\text{Comm}}(\mathcal{C}) \to \mathcal{C}$. We will often abuse notation by identifying $\mathcal{C}$-monoids with the theory of $\mathcal{O}$-algebras:

Example 2.4.2.4. Let $\mathcal{O}^\otimes$ be an $\infty$-operad. A functor $M : \mathcal{O}^\otimes \to \text{Cat}_{\infty}$ is a $\mathcal{O}$-monoid in $\text{Cat}_{\infty}$ if and only if the coCartesian fibration $\mathcal{C}^\otimes \to \mathcal{O}^\otimes$ classified by $M$ is a $\mathcal{O}$-monoidal $\infty$-category.

We now compare the theory of $\mathcal{O}$-monoids with the theory of $\mathcal{O}$-algebras:

Proposition 2.4.2.5. Let $\mathcal{C}^\otimes$ be a symmetric monoidal $\infty$-category, $\pi : \mathcal{C}^\otimes \to \mathcal{D}$ a Cartesian structure, and $\mathcal{O}^\otimes$ an $\infty$-operad. Then composition with $\pi$ induces an equivalence of $\infty$-categories $\text{Alg}_{\mathcal{O}}(\mathcal{C}) \to \text{Mono}_{\mathcal{O}}(\mathcal{D})$.

Proof. As in the proof of Corollary 2.4.1.9, we may assume without loss of generality that $\mathcal{C}^\otimes = \mathcal{D}^\otimes$. We now apply Proposition 2.4.1.7 again to deduce that the map

$$\text{Alg}_{\mathcal{O}}(\mathcal{C}) \to \text{Fun}_{\text{lax}}(\mathcal{O}^\otimes, \mathcal{D}) = \text{Mono}_{\mathcal{O}}(\mathcal{D})$$

is a trivial Kan fibration.

Remark 2.4.2.6. Let $\mathcal{O}^\otimes$ be an $\infty$-operad. Combining Proposition 2.4.2.5 with Example 2.4.2.4, we see that $\mathcal{O}$-monoidal $\infty$-categories can be identified with $\mathcal{O}$-algebra objects of $\text{Cat}_{\infty}$ (where we endow the latter with the Cartesian monoidal structure). More precisely, we have a canonical equivalence of $\infty$-categories $\text{Alg}_{\mathcal{O}}(\text{Cat}_{\infty}) \simeq \text{Cat}_{\mathcal{O}}^\otimes$, where $\text{Cat}_{\mathcal{O}}^\otimes$ denotes the subcategory of $(\text{Op}_{\infty})/\mathcal{O}^\otimes$ spanned by the $\mathcal{O}$-monoidal $\infty$-categories and $\mathcal{O}$-monoidal functors between them. This observation will play a vital role in Chapter 4.

Remark 2.4.2.7. Let $\text{Cat}_{\infty}^\Delta$ denote the simplicial category whose objects are small $\infty$-categories, where $\text{Map}_{\text{Cat}_{\infty}^\Delta}(\mathcal{C}, \mathcal{D})$ is the Kan complex $\text{Fun}(\mathcal{C}, \mathcal{D})^\otimes$. Let $|\text{Cat}_{\infty}^\Delta|$ denote the geometric realization of $\text{Cat}_{\infty}^\Delta$: that is, the topological category with the same objects, but with morphisms given by $\text{Map}_{\text{Cat}_{\infty}^\Delta}(\mathcal{C}, \mathcal{D}) = |\text{Map}_{\text{Cat}_{\infty}^\Delta}(\mathcal{C}, \mathcal{D})|$. Let $\text{Cat}_{\infty}'$ denote the nerve of the topological category $|\text{Cat}_{\infty}^\Delta|$, so we have an equivalence of $\infty$-categories $\text{Cat}_{\infty} \simeq N(\text{Cat}_{\infty}^\Delta) \to N(|\text{Cat}_{\infty}^\Delta|) = \text{Cat}_{\infty}'$. Using the existence of the canonical homeomorphism $|K| \simeq |K^{op}|$ for every simplicial set $K$, we deduce the existence of an involution $R$ on the $\infty$-category $\text{Cat}_{\infty}'$, which carries each $\infty$-category $\mathcal{C}$ to its opposite $\infty$-category $\mathcal{C}^{op}$.

The definition of a symmetric monoidal $\infty$-category is not manifestly self-dual. However, it is nevertheless true that any symmetric monoidal structure on an $\infty$-category $\mathcal{C}$ determines a symmetric monoidal structure on $\mathcal{C}^{op}$, which is unique up to contractible ambiguity. Roughly speaking, we can use Example 2.4.2.4 to identify symmetric monoidal $\infty$-categories $\mathcal{C}$ with commutative monoids $N(\text{Fin}_*) \to \text{Cat}_{\infty} \simeq \text{Cat}_{\infty}'$. We can then obtain a new commutative monoid object by composing with the self-equivalence $R : \text{Cat}_{\infty}' \to \text{Cat}_{\infty}'$, which carries each $\infty$-category to its opposite. More formally: composition with the self-equivalence $R$ allows us to pass between symmetric monoidal structures on an $\infty$-category $\mathcal{C}$ and symmetric monoidal structures on the opposite $\infty$-category $R(\mathcal{C}) = \mathcal{C}^{op}$. We will discuss this phenomenon in more detail in §5.2.2 (see Example 5.2.2.23).
2.4.3 CoCartesian Symmetric Monoidal Structures

Let \( \mathcal{C} \) be an \( \infty \)-category which admits finite coproducts. Then the opposite \( \infty \)-category \( \mathcal{C}^{op} \) admits finite products, and can therefore be endowed with a Cartesian symmetric monoidal structure, which is unique up to equivalence (see §2.4.1). Using Remark 2.4.2.7, we deduce that the \( \infty \)-category \( \mathcal{C} \) inherits a symmetric monoidal structure, which is determined uniquely up to equivalence by the requirement that it be coCartesian (in the sense of Definition 2.4.0.1). Our goal in this section is to give an explicit construction of this symmetric monoidal structure, which is determined uniquely up to equivalence by the requirement that it be coCartesian (in the sense of Definition 2.4.0.1).

We now define the \( \infty \)-operad \( \mathcal{C}^{II} \), where the morphism spaces are described informally by the formula

\[
\text{Mul}_{\mathcal{C}}(C_1 \oplus \cdots \oplus C_n, D) \simeq \prod_{1 \leq i \leq n} \text{Map}_{\mathcal{C}}(C_i, D).
\]

We now define the \( \infty \)-operad \( \mathcal{C}^{II} \) more precisely.

**Construction 2.4.3.1.** We define a category \( \Gamma^* \) as follows:

1. The objects of \( \Gamma^* \) are pairs \((\langle n \rangle, i)\) where \( i \in \langle n \rangle^0 \).

2. A morphism in \( \Gamma^* \) from \((\langle m \rangle, i)\) to \((\langle n \rangle, j)\) is a map of pointed sets \( \alpha : \langle m \rangle \to \langle n \rangle \) such that \( \alpha(i) = j \).

Let \( \mathcal{C} \) be any simplicial set. We define a new simplicial set \( \mathcal{C}^{II} \) equipped with a map \( \mathcal{C}^{II} \rightarrow N(\text{Fin}_*) \) so that the following universal property is satisfied: for every map of simplicial sets \( K \rightarrow N(\text{Fin}_*) \), we have a canonical bijection

\[
\text{Hom}_{N(\text{Fin}_*)}(K, \mathcal{C}^{II}) \simeq \text{Hom}_{\Delta}(K \times_{N(\text{Fin}_*)} N(\Gamma^*), \mathcal{C}).
\]

**Remark 2.4.3.2.** If \( \mathcal{C} \) is a simplicial set, then each fiber \( \mathcal{C}^{II}_{\langle n \rangle} = \mathcal{C}^{II} \times_{N(\text{Fin}_*)} \{\langle n \rangle\} \) can be identified with \( \mathcal{C}^n \); we will henceforth invoke these identifications implicitly.

**Proposition 2.4.3.3.** Let \( \mathcal{C} \) be an \( \infty \)-category. Then the map \( p : \mathcal{C}^{II} \rightarrow N(\text{Fin}_*) \) of Construction 2.4.3.1 is an \( \infty \)-operad.

**Proof.** We first show that \( p \) is an inner fibration of simplicial sets. Suppose we are given a lifting problem

\[
\xymatrix{
\Lambda^n_i \ar[r]^{f_0} \ar[d] & \mathcal{C}^{II} \ar[d]^{f} \\
\Delta^n \ar[r] & N(\text{Fin}_*)
}
\]

where \( 0 < i < n \). The lower horizontal map determines a sequence of maps \( \langle k_0 \rangle \rightarrow \cdots \rightarrow \langle k_n \rangle \) in \( \text{Fin}_* \). Unwinding the definitions, we see that finding the desired extension \( f \) of \( f_0 \) is equivalent to the problem of solving a series of extension problems

\[
\xymatrix{
\Lambda^n_i \ar[r]^{f_0'} \ar[d] & \mathcal{C} \ar[d]^{f'} \\
\Delta^n \ar[r] & \mathcal{C}
}
\]

indexed by those elements \( j \in \langle k_0 \rangle^0 \) whose image in \( \langle k_n \rangle \) belongs to \( \langle k_n \rangle^0 \). These extensions exist by virtue of the assumption that \( \mathcal{C} \) is an \( \infty \)-category. If \( i = 0 \) and the map \( \langle k_0 \rangle \rightarrow \langle k_1 \rangle \) is inert, then the same argument applies: we conclude that the desired extension of \( f \) exists provided that \( n \geq 2 \) and \( f_0' \) carries \( \Delta^{(0,1)} \) to an equivalence in \( \mathcal{C} \).

Unwinding the definitions, we see that an object of \( \mathcal{C}^{II} \) consists of an object \( \langle n \rangle \in \text{Fin}_* \) together with a sequence of objects \( (C_1, \ldots, C_n) \) in \( \mathcal{C} \). A morphism \( f \) from \( (C_1, \ldots, C_m) \) to \( (C'_1, \ldots, C'_n) \) in \( \mathcal{C}^{II} \) consists of a
map of pointed sets \( \alpha : \langle m \rangle \rightarrow \langle n \rangle \) together with a sequence of morphisms \( \{ f_i : C_i \rightarrow C'_{\alpha(i)} \}_{i \in \alpha^{-1}(n)^*} \). The above argument shows that \( f \) is p-coCartesian if \( \alpha \) is inert and each of the maps \( f_i \) is an equivalence in \( \mathcal{C} \). In particular (taking each \( f_i \) to be the identity map), we deduce that for every object \( C \in \mathcal{C}^{(m)}_n \) and every inert morphism \( \alpha : \langle m \rangle \rightarrow \langle n \rangle \) in \( \mathcal{F} \mathcal{i} \mathcal{n}_* \), there exists a p-coCartesian morphism \( C \rightarrow C' \) in \( \mathcal{C}^{(m)}_n \) lifting \( \alpha \).

Let \( C = (C_1, \ldots, C_n) \) be an object of \( \mathcal{C}^{(n)}_n \) and choose p-coCartesian morphisms \( C \rightarrow C'_i \) covering \( \rho^i \) for \( 1 \leq i \leq n \), corresponding to equivalences \( g_i : C_i \simeq C'_i \) in \( \mathcal{C} \). These morphisms determine a diagram \( \bar{\eta} : \langle n \rangle^\circ \rightarrow \mathcal{C}^{(n)}_n \); we must show that \( \bar{\eta} \) is a p-limit diagram. To prove this, we must show that it is possible to solve lifting problems of the form

\[
\partial \Delta^m \ast \langle n \rangle^\circ \xrightarrow{f_0} \mathcal{C}^{(m)}_n \xrightarrow{f} \mathcal{C}^{(n)}_n.
\]

provided that \( f_0((\{m\} \ast \langle n \rangle)^\circ) \) is given by \( \bar{\eta} \). Unwinding the definitions, we see that this is equivalent to solving a collection of extension problems of the form

\[
\Lambda^m_{n+1} \xrightarrow{f_0} \mathcal{C}^{(m+1)}_{n+1} \xrightarrow{f'} \mathcal{C}^{(n)}_n.
\]

where \( f_0' \) carries the final edge of \( \Delta^m_{n+1} \) to one of the morphisms \( g_i \). This is possible by virtue of our assumption that each \( g_i \) is an equivalence.

To complete the proof that \( \mathcal{C}^{(m)}_n \) is an \( \infty \)-operad, it suffices to show that for each \( n \geq 0 \), the functors \( \rho^i : \mathcal{C}^{(n)}_n \rightarrow \mathcal{C}^{(1)}_1 \) induce an equivalence \( \theta : \mathcal{C}^{(m)}_n \rightarrow \prod_{1 \leq i \leq n} \mathcal{C}^{(1)}_1 \). In fact, we have canonical isomorphisms of simplicial sets \( \mathcal{C}^{(n)}_n \simeq \mathcal{C}^n \) which allow us to identify \( \theta \) with \( \text{id}_{\mathcal{C}^n} \).

**Remark 2.4.3.4.** Unwinding the definitions, we deduce that a map \( (C_1, \ldots, C_m) \rightarrow (C'_1, \ldots, C'_n) \) in \( \mathcal{C}^{(m)}_n \) covering a map \( \alpha : \langle m \rangle \rightarrow \langle n \rangle \) is p-coCartesian if and only if for each \( j \in \langle n \rangle^\circ \), the underlying maps \( \{ f_i : C_i \rightarrow C'_j \}_{i \in \alpha^{-1}(j)} \) exhibit \( C'_j \) as a coproduct of \( \{ C_i \}_{i \in \alpha^{-1}(j)} \) in the \( \infty \)-category \( \mathcal{C} \). It follows that \( \mathcal{C}^{(m)}_n \) is a symmetric monoidal \( \infty \)-category if and only if \( \mathcal{C} \) admits finite coproducts. If this condition is satisfied, then \( \mathcal{C}^{(m)}_n \) determines a coCartesian symmetric monoidal structure on \( \mathcal{C} \) and is therefore determined by \( \mathcal{C} \) up to essentially unique equivalence. We will see that the situation is similar even if \( \mathcal{C} \) does not admit finite coproducts.

**Example 2.4.3.5.** The projection map \( N(\Gamma^*) \rightarrow N(\mathcal{F} \mathcal{i} \mathcal{n}_*) \) induces a canonical map \( \mathcal{C} \times N(\mathcal{F} \mathcal{i} \mathcal{n}_*) \rightarrow \mathcal{C}^{(m)}_n \). If \( \mathcal{C} = \Delta^0 \), this map is an isomorphism (so that \( \mathcal{C}^{(m)}_n \) is the commutative \( \infty \)-operad \( N(\mathcal{F} \mathcal{i} \mathcal{n}_*) \)). For any \( \infty \)-operad \( \mathcal{O}^\circ \), we obtain a map \( \mathcal{C} \times \mathcal{O}^\circ \rightarrow \mathcal{C}^{(m)}_n \times N(\mathcal{F} \mathcal{i} \mathcal{n}_*) \mathcal{O}^\circ \) which determines a functor \( \mathcal{C} \rightarrow \text{Alg}_0(A) \), where \( A^\circ \) is the \( \infty \)-operad \( \mathcal{C}^{(m)}_n \times N(\mathcal{F} \mathcal{i} \mathcal{n}_*) \mathcal{O}^\circ \).

**Remark 2.4.3.6.** Let \( \mathcal{C} \) be an \( \infty \)-category, and let \( \gamma : \mathcal{C} \times N(\mathcal{F} \mathcal{i} \mathcal{n}_*) \rightarrow \mathcal{C}^{(m)}_n \) be the canonical map, where \( \mathcal{C}^{(m)}_n \). Then \( \gamma \) is an approximation to the \( \infty \)-operad \( \mathcal{C}^{(m)}_n \). Unwinding the definitions, this is equivalent to the observation that for every object \( C \in \mathcal{C} \) and each \( n \geq 0 \), the \( \infty \)-category \( \mathcal{C}^{(m)}_n \) has a final object (given by \((C, C, \ldots, C)\)).

**Definition 2.4.3.7.** We will say that an \( \infty \)-operad \( \mathcal{O}^\circ \) is coCartesian if it is equivalent to \( \mathcal{C}^{(m)}_n \), for some \( \infty \)-category \( \mathcal{C} \).

The following result shows that a coCartesian \( \infty \)-operad \( \mathcal{O}^\circ \) is determined, in a very strong sense, by the underlying \( \infty \)-category \( \mathcal{C} \):
Proposition 2.4.3.8. Let $\mathcal{C}^\otimes$ and $D^\otimes$ be coCartesian $\infty$-operads. Then the restriction functor $\text{Alg}_{\mathcal{C}}(D) \to \text{Fun}(\mathcal{C}, D)$ is an equivalence of $\infty$-categories.

We observe that for every $\infty$-category $\mathcal{C}$, the $\infty$-operad $\mathcal{C}^\Pi$ is unital. Consequently, Proposition 2.4.3.8 is a consequence of the following more general assertion:

Proposition 2.4.3.9. Let $\mathcal{O}^\otimes$ be a unital $\infty$-operad and let $\mathcal{C}^\otimes$ be a coCartesian $\infty$-operad. Then the restriction functor $\text{Alg}_{\mathcal{O}}(\mathcal{C}) \to \text{Fun}(\mathcal{O}, \mathcal{C})$ is an equivalence of $\infty$-categories.

Corollary 2.4.3.10. Let $\mathcal{C}$ be an $\infty$-category, which we regard as the underlying $\infty$-category of the $\infty$-operad $\mathcal{C}^\Pi$. Then the construction of Example 2.4.3.5 induces an equivalence of $\infty$-categories $\mathcal{C} \to \text{CAlg}(\mathcal{C})$.

Corollary 2.4.3.11. Let $\text{Op}_\infty^\Pi$ denote the full subcategory of $\text{Op}_\infty$ spanned by the coCartesian $\infty$-operads, and let $\theta : \text{Op}_\infty^\Pi \to \text{Cat}_\infty$ denote the forgetful functor (given on objects by $\mathcal{O}^\otimes \to \mathcal{O}$). Then $\theta$ is an equivalence of $\infty$-categories.

Proof. It follows from Proposition 2.4.3.16 that $\theta$ is fully faithful. Construction 2.4.3.1 shows that $\theta$ is essentially surjective.

Variant 2.4.3.12. Let $\text{Cat}_\infty^\otimes$ denote the $\infty$-category of symmetric monoidal $\infty$-categories and let $\text{Cat}_\infty^{\otimes, \Pi} \subseteq \text{Cat}_\infty^\otimes$ denote the full subcategory spanned by the coCartesian symmetric monoidal $\infty$-categories. Let $\text{Cat}_\infty^{\otimes, \text{coCart}}$ denote the subcategory of $\text{Cat}_\infty^\otimes$ spanned by those $\infty$-categories which admit finite coproducts and whose functors which preserve finite coproducts. Then the restriction functor $\text{Cat}_\infty^{\otimes, \Pi} \to \text{Cat}_\infty^{\otimes, \text{coCart}}$ is an equivalence of $\infty$-categories. This can be deduced either from the equivalence of Corollary 2.4.3.11 (by identifying $\text{Cat}_\infty^\otimes$ and $\text{Cat}_\infty^{\otimes, \text{coCart}}$ with subcategories of $\text{Op}_\infty^\Pi$ and $\text{Cat}_\infty$) or from the equivalence of Corollary 2.4.1.9 (by passing to opposite $\infty$-categories; see Remark 2.4.2.7).

For later use, we formulate an even more general version of Proposition 2.4.3.8.

Definition 2.4.3.13. Let $\mathcal{C}$ be an $\infty$-category. We will say that a $\mathcal{C}$-family of $\infty$-operads $q : O^\otimes \to \mathcal{C} \times N(\mathcal{F}_{\text{Fin}_*})$ is unital if every object of $O^\otimes(0) = \mathcal{O}^\otimes \times N(\mathcal{F}_{\text{Fin}_*}) \{0\}$ is $q$-initial.

Remark 2.4.3.14. In the special case where $\mathcal{C} = \Delta^0$, the notion of a unital $\mathcal{C}$-family of $\infty$-operads coincides with the notion of unital $\infty$-operad introduced in Definition 2.3.1.1. More generally, if $O^\otimes \to \mathcal{C} \times N(\mathcal{F}_{\text{Fin}_*})$ is a unital $\mathcal{C}$-family of $\infty$-operads, then for each $C \in \mathcal{C}$ the fiber $O^\otimes_C$ is a unital $\infty$-operad. If $\mathcal{C}$ is a Kan complex, then the converse is true as well: a $\mathcal{C}$-family of $\infty$-operads is unital if and only if each fiber is unital.

Remark 2.4.3.15. Let $O^\otimes$ be a generalized $\infty$-operad. Then $O^\otimes$ is categorically equivalent to a $\mathcal{C}$-family of $\infty$-operads $\mathcal{O}^\otimes \to \mathcal{C} \times N(\mathcal{F}_{\text{Fin}_*})$, where $\mathcal{C} = O^\otimes(0)$ (see Corollary 2.3.2.13), which is uniquely determined up to equivalence. We will say that $O^\otimes$ is unital if $O^\otimes$ is a unital $\mathcal{C}$-family of $\infty$-operads, in the sense of Definition 2.4.3.13.

Proposition 2.4.3.9 is an immediate consequence of the following:

Proposition 2.4.3.16. Let $O^\otimes$ be a unital generalized $\infty$-operad and let $\mathcal{C}^\otimes$ be a coCartesian $\infty$-operad. Then the restriction functor $\text{Alg}_{O^\otimes}(\mathcal{C}) \to \text{Fun}(O^\otimes, \mathcal{C})$ is an equivalence of $\infty$-categories.

Proof. We may assume without loss of generality that $\mathcal{C}^\otimes = \mathcal{C}^\Pi$ for some $\infty$-category $\mathcal{C}$. Let $\mathcal{D}$ denote the fiber product

$$O^\otimes \times_{N(\mathcal{F}_{\text{Fin}_*})} N(\Delta^*)$$

By definition, a map $O^\otimes \to \mathcal{C}^\Pi$ in $(\text{Set}_{\Delta})_{/N(\mathcal{F}_{\text{Fin}_*})}$ can be identified with a functor $A : \mathcal{D} \to \mathcal{C}$. Such a functor determines a map of generalized $\infty$-operads if and only if the following condition is satisfied:

\[(\ast)\] Let $\alpha$ be a morphism in $\mathcal{D}$ whose image in $O^\otimes$ is inert. Then $A(\alpha)$ is an equivalence in $\mathcal{C}$. 

We can identify \( \text{Alg}_\mathcal{O}(\mathcal{C}) \) with the full subcategory of \( \text{Fun}(\mathcal{D}, \mathcal{C}) \) spanned by those functors which satisfy \((*)\).

We observe that the inverse image in \( \mathcal{D} \) of \( \langle 1 \rangle \in \mathcal{N}(\mathcal{F} \text{in}_n) \) is canonically isomorphic to \( \mathcal{O} \). Via this isomorphism, we will regard \( \mathcal{O} \) as a full subcategory of \( \mathcal{D} \). In view of Proposition T.4.3.2.15, it will suffice to prove the following:

(a) A functor \( A : \mathcal{D} \to \mathcal{C} \) is a left Kan extension of \( A|\mathcal{O} \) if and only if it satisfies condition \((*)\).

(b) Every functor \( A_0 : \mathcal{O} \to \mathcal{C} \) admits an extension \( A : \mathcal{D} \to \mathcal{C} \) satisfying the equivalent conditions of (a).

We can identify objects of \( \mathcal{D} \) with pairs \((X, i)\), where \( X \in \mathcal{O}^\otimes_{(n)} \) and \( 1 \leq i \leq n \). For every such pair, choose an inert morphism \( X \to X_i \) lying over the map \( \rho^i : \langle n \rangle \to \langle 1 \rangle \). We then have a morphism \( f : (X, i) \to (X_i, 1) \) in \( \mathcal{D} \). Using the assumption that \( \mathcal{O}^\otimes \) is unital, we deduce that the map

\[
\text{Map}_\mathcal{D}(Y, (X, i)) \to \text{Map}_\mathcal{D}(Y, (X_i, 1)) \cong \text{Map}_\mathcal{O}(Y, X_i)
\]

is a homotopy equivalence for each \( Y \in \mathcal{O} \subseteq \mathcal{D} \). In particular, we conclude that \( f \) admits a right homotopy inverse \( g : (X_i, 1) \to (X, i) \). It follows that composition with \( g \) induces a homotopy equivalence

\[
\text{Map}_\mathcal{D}(Y, (X_i, 1)) \to \text{Map}_\mathcal{D}(Y, (X, i))
\]

for each \( Y \in \mathcal{O} \). This implies that the inclusion \( \mathcal{O} \subseteq \mathcal{D} \) admits a right adjoint \( G \), given by \( (X, i) \mapsto (X_i, 1) \). This immediately implies (b) (we can take \( A = A_0 \circ G \)) together with the following version of (a):

(a') A functor \( A : \mathcal{D} \to \mathcal{C} \) is a left Kan extension of \( A|\mathcal{O} \) if and only if, for every object \((X, i) \in \mathcal{D}, \) the map \( A(g) \) is an equivalence in \( \mathcal{C} \), where \( g : (X_i, 1) \to (X, i) \) is defined as above.

Since \( g \) is a right homotopy inverse to the inert morphism \( f : (X, i) \to (X_i, 1) \), assertion (a') can be reformulated as follows: a functor \( A : \mathcal{D} \to \mathcal{C} \) is a left Kan extension of \( A|\mathcal{O} \) if and only if the following condition is satisfied:

(*') Let \((X, i) \in \mathcal{D} \) be an object, and let \( f : (X, i) \to (X_i, 1) \) be defined as above. Then \( A(f) \) is an equivalence in \( \mathcal{C} \).

To complete the proof, it will suffice to show that conditions (*) and (*') are equivalent. The implication \((*) \Rightarrow (*')\) is obvious. For the converse, suppose that \( h : (Y, j) \to (X, i) \) is an arbitrary morphism in \( \mathcal{D} \) whose image in \( \mathcal{O}^\otimes \) is inert. We then have a commutative diagram

\[
\begin{array}{ccc}
(Y, j) & \xrightarrow{f} & (X, i) \\
\downarrow{f'} & & \downarrow{f''} \\
(X_i, 1) & & \\
\end{array}
\]

Condition (*') guarantees that \( A(f') \) and \( A(f'') \) are equivalences, so that \( A(f) \) is an equivalence by the two-out-of-three property.

\[\Box\]

**Remark 2.4.3.17.** Let \( \mathcal{C}^\otimes \) be a symmetric monoidal \( \infty \)-category. Then \( \mathcal{C}^\otimes \) is coCartesian as a symmetric monoidal \( \infty \)-category (in the sense of Definition 2.4.0.1) if and only if it is coCartesian as an \( \infty \)-operad (in the sense of Definition 2.4.3.7). This follows from the uniqueness of coCartesian symmetric monoidal structures (combine Remark 2.4.2.7 with Corollary 2.4.1.8), since \( \mathcal{C}^\otimes \) satisfies the requirements of Definition A.5.12.

Let \( \mathcal{C} \) be a category which admits finite coproducts. The construction \((X, Y) \mapsto X \coprod Y\) endows \( \mathcal{C} \) with the structure of a symmetric monoidal category. For every object \( C \in \mathcal{C} \), the codiagonal \( C \coprod C \to C \) exhibits \( C \) as a commutative algebra object of \( \mathcal{C} \). Corollary 2.4.3.10 can be regarded as an \( \infty \)-categorical analogue.
of this assertion: it guarantees that the forgetful functor \( \text{CAlg}(\mathcal{C}) \to \mathcal{C} \) is an equivalence of \( \infty \)-categories for any coCartesian \( \infty \)-operad \( \mathcal{O}^{\otimes} \), and therefore admits a homotopy inverse \( \mathcal{C} \to \text{CAlg}(\mathcal{D}) \). Our goal in this section is to prove a converse: namely, we will show that if \( \mathcal{D}^{\otimes} \) is an arbitrary \( \infty \)-operad, then every functor \( \mathcal{C} \to \text{CAlg}(\mathcal{D}) \) is induced by a map of \( \infty \)-operads \( \mathcal{C}^{\otimes} \to \mathcal{D}^{\otimes} \). This is a consequence of the following more general assertion:

**Theorem 2.4.3.18.** Let \( \mathcal{C} \) be an \( \infty \)-category, let \( \mathcal{O}^{\otimes} \) and \( \mathcal{D}^{\otimes} \) be \( \infty \)-operads, and let \( \mathcal{O}'^{\otimes} \) denote the fiber product \( \mathcal{C}^{\otimes} \times_{N(\text{Fin}_*)} \mathcal{O}^{\otimes} \). Then the construction of Example 2.4.3.5 induces a trivial Kan fibration

\[
\theta : \text{Alg}_{\mathcal{O}'}(\mathcal{D}) \to \text{Fun}(\mathcal{C}, \text{CAlg}(\mathcal{D})).
\]

In particular (taking \( \mathcal{O}^{\otimes} \) to be the commutative \( \infty \)-operad), we have a trivial Kan fibration \( \text{Alg}_{\mathcal{C}}(\mathcal{D}) \to \text{Fun}(\mathcal{C}, \text{CAlg}(\mathcal{D})) \).

**Proof.** Note that the map \( f : \mathcal{C} \times \mathcal{O}^{\otimes} \to \mathcal{C}^{\otimes} \times_{N(\text{Fin}_*)} \mathcal{O}^{\otimes} \) induces an isomorphism after passing to the fiber over the object \( 1 \in N(\text{Fin}_*) \). According to Theorem 2.3.3.23, it will suffice to show that \( f \) is an approximation to \( \mathcal{C}^{\otimes} \times_{N(\text{Fin}_*)} \mathcal{O}^{\otimes} \). This follows from Remarks 2.3.3.19 and 2.4.3.6. \( \square \)

We conclude this section with a simple criterion which is useful for establishing that a symmetric monoidal structure on an \( \infty \)-category is coCartesian:

**Proposition 2.4.3.19.** Let \( \mathcal{C} \) be a symmetric monoidal \( \infty \)-category. The following conditions are equivalent:

1. The symmetric monoidal structure on \( \mathcal{C} \) is coCartesian.
2. The induced symmetric monoidal structure on the homotopy category \( \text{hC} \) is coCartesian.
3. The unit object \( 1_C \) is initial, and for each object \( C \in \mathcal{C} \) there exists a codiagonal map \( \delta_C : C \otimes C \to C \) satisfying the following conditions:
   i. Let \( C \) be an object of \( \mathcal{C} \) and let \( u : 1_C \to C \) be a map (automatically unique up to homotopy). Then the composition
      \[
      C \simeq C \otimes 1_C \xrightarrow{id \otimes u} C \otimes C \xrightarrow{\delta_C} C
      \]
      is homotopic to the identity.
   ii. For every morphism \( f : C \to D \) in \( \mathcal{C} \), the diagram
       \[
       \begin{array}{ccc}
       C \otimes C & \xrightarrow{f \otimes f} & D \otimes D \\
       \downarrow{\delta_C} & & \downarrow{\delta_D} \\
       C & \xrightarrow{f} & D
       \end{array}
       \]
       commutes up to homotopy.
   iii. Let \( C \) and \( D \) be objects of \( \mathcal{C} \). Then the diagram
       \[
       \begin{array}{ccc}
       (C \otimes C) \otimes (D \otimes D) & \xrightarrow{\sim} & (C \otimes D) \otimes (C \otimes D) \\
       \downarrow{\delta_C \otimes \delta_D} & & \downarrow{\delta_{C \otimes D}} \\
       C \otimes D & &
       \end{array}
       \]
       commutes up to homotopy.
Proof. The implications (1) \(\Rightarrow\) (2) \(\Rightarrow\) (3) are obvious. Let us suppose that (3) is satisfied. We wish to show that, for every pair of objects \(C,D \in \mathcal{E}\), the maps
\[
C \simeq C \otimes 1_c \to C \otimes D \leftarrow 1_c \otimes D \simeq D
\]
evit \(C \otimes D\) as a coproduct of \(C\) and \(D\) in \(\mathcal{E}\). In other words, we must show that for every object \(A \in \mathcal{E}\), the induced map
\[
\phi : \text{Map}_\mathcal{E}(C \otimes D, A) \to \text{Map}_\mathcal{E}(C, A) \times \text{Map}_\mathcal{E}(D, A)
\]
is a homotopy equivalence. Let \(\psi\) denote the composition
\[
\text{Map}_\mathcal{E}(C, A) \otimes \text{Map}_\mathcal{E}(D, A) \xrightarrow{\delta} \text{Map}_\mathcal{E}(C \otimes D, A).
\]
We claim that \(\psi\) is a homotopy inverse to \(\phi\). The existence of a homotopy \(\psi \circ \phi \simeq \text{id}\) follows from (i). We will show that \(\psi \circ \phi\) is homotopic to the identity. In view of condition (ii), \(\psi \circ \phi\) is homotopic to the map defined by composition with
\[
C \otimes D \simeq (C \otimes 1_c) \otimes (1_c \otimes D) \to (C \otimes D) \otimes (C \otimes D) \xrightarrow{\delta_{C\otimes D}} C \otimes D.
\]
It follows from (iii) and (i) that this map is homotopic to the identity. \(\square\)

### 2.4.4 Wreath Products

In §2.2.5, we saw that every pair of \(\infty\)-operads \(\mathcal{O}^\otimes\) and \(\mathcal{O}'^\otimes\) admit a tensor product \(\mathcal{O}^\otimes \odot \mathcal{O}'^\otimes\), which is well-defined up to equivalence. However, it can be very difficult to describe this tensor product directly. By definition, it is given by a fibrant replacement for the product \(\mathcal{O}^\otimes \otimes \mathcal{O}'^\otimes\) in the category \(\mathcal{F}Op_{\infty}\) of \(\infty\)-preoperads. This product is almost never itself fibrant, and the process of fibrant replacement is fairly inexplicit. Our goal in this section is to partially address this problem by introducing another construction: the wreath product \(\mathcal{O}^\otimes \wr \mathcal{O}'^\otimes\) of a pair of \(\infty\)-operads \(\mathcal{O}^\otimes\) and \(\mathcal{O}'^\otimes\). This wreath product is an \(\infty\)-category which admits a forgetful functor \(\mathcal{O}^\otimes \wr \mathcal{O}'^\otimes \to N(\mathcal{F}in_\ast)\), together with a distinguished class \(M\) of inert morphisms, so that \((\mathcal{O}^\otimes \wr \mathcal{O}'^\otimes, M)\) can be regarded as an \(\infty\)-preoperad. Our main result, Theorem 2.4.4.3, asserts that there is a weak equivalence of \(\infty\)-preoperads \(\mathcal{O}^\otimes \wr \mathcal{O}'^\otimes \to (\mathcal{O}^\otimes \odot \mathcal{O}'^\otimes, M)\). This is not really a complete answer, since the codomain \((\mathcal{O}^\otimes \odot \mathcal{O}'^\otimes, M)\) is still generally not fibrant. However, it is in many ways more convenient than the product \(\mathcal{O}^\otimes \otimes \mathcal{O}'^\otimes\), and will play a vital role in our analysis of tensor products of little cubes \(\infty\)-operads in §5.1.2.

**Construction 2.4.4.1.** If \(\mathcal{E}\) is an \(\infty\)-category, we let \(\mathcal{E}^\Pi\) be defined as in Construction 2.4.3.1. Note that if \(\mathcal{E}\) is the nerve of a category \(\mathcal{J}\), then \(\mathcal{E}^\Pi\) can be identified with the nerve of the category \(\mathcal{J}^\Pi\) defined as follows:

(i) The objects of \(\mathcal{J}^\Pi\) are finite sequences \((J_1, \ldots, J_n)\) of objects in \(\mathcal{J}\).

(ii) A morphism from \((I_1, \ldots, I_m)\) to \((J_1, \ldots, J_n)\) in \(\mathcal{J}^\Pi\) consists of a map \(\alpha : \langle m \rangle \to \langle n \rangle\) in \(\mathcal{F}in_\ast\) together with a collection of maps \(\{I_i \to J_j\}_{\alpha(i)=j}\).

There is an evident functor \(\mathcal{F}in_\ast^\Pi \to \mathcal{F}in_\ast\), given on objects by the formula
\[
(\langle k_1, \ldots, k_n \rangle) \mapsto k_1 + \cdots + k_n.
\]
This functor induces a map \(\Phi : N(\mathcal{F}in_\ast)^\Pi \to N(\mathcal{F}in_\ast)\).

Let \(\mathcal{E}^\otimes\) and \(\mathcal{D}^\otimes\) be \(\infty\)-operads. We let \(\mathcal{E}^\otimes \times_{N(\mathcal{F}in_\ast)} (\mathcal{D}^\otimes)^\Pi\).
We define a map of simplicial sets
\[
\mathcal{C} \otimes \mathcal{D} \to N(\mathcal{F}_{\text{Fin}_\ast})
\]
by considering the composition
\[
\mathcal{C} \otimes \mathcal{D} = \mathcal{C} \times_{N(\mathcal{F}_{\text{Fin}_\ast})}(\mathcal{D}^\otimes)^{\Pi} \to (\mathcal{D}^\otimes)^{\Pi} \to N(\mathcal{F}_{\text{Fin}_\ast})^{\Pi} \to N(\mathcal{F}_{\text{Fin}_\ast}).
\]

We can identify a morphism \( f \) in \( \mathcal{C} \otimes \mathcal{D} \) with a map \( g : (D_1, \ldots, D_m) \to (D'_1, \ldots, D'_n) \) in \( (\mathcal{D}^\otimes)^{\Pi} \) lying over \( \alpha : (m) \to (n) \) in \( N(\mathcal{F}_{\text{Fin}_\ast}) \), together with a map \( h : C \to C' \) in \( \mathcal{D}^\otimes \) lying over \( \alpha \). We will say that \( f \) is inert if \( h \) is an inert morphism in \( \mathcal{D}^\otimes \) and \( g \) determines a set of inert morphisms \( \{ D_i \to D'_j \}_{\alpha(i) = j} \) in \( \mathcal{D}^\otimes \).

Remark 2.4.4.2. Let \( \mathcal{C}^\otimes \) and \( \mathcal{D}^\otimes \) be \( \infty \)-operads. The map \( \mathcal{D}^\otimes \times N(\mathcal{F}_{\text{Fin}_\ast}) \to (\mathcal{D}^\otimes)^{\Pi} \) of Example 2.4.3.5 induces a monomorphism of simplicial sets \( \mathcal{C}^\otimes \times \mathcal{D}^\otimes \to \mathcal{C}^\otimes \otimes \mathcal{D}^\otimes \).

The remainder of this section is devoted to proving the following technical result:

Theorem 2.4.4.3. Let \( \mathcal{C}^\otimes \) and \( \mathcal{D}^\otimes \) be \( \infty \)-operads, and let \( M \) be the collection of inert morphisms in \( \mathcal{C}^\otimes \otimes \mathcal{D}^\otimes \). Then the inclusion \( \mathcal{C}^\otimes \times \mathcal{D}^\otimes \to \mathcal{C}^\otimes \otimes \mathcal{D}^\otimes \) of Remark 2.4.4.2 induces a weak equivalence of \( \infty \)-preoperads
\[
\mathcal{C}^\otimes \otimes \mathcal{D}^\otimes \to (\mathcal{C}^\otimes \otimes \mathcal{D}^\otimes, M).
\]

Lemma 2.4.4.4. Let \( S \) be a finite set (regarded as a discrete simplicial set), let \( v \) denote the cone point of \( S^\otimes \), and suppose we are given coCartesian fibrations \( p : X \to S^d \) and \( q : Y \to S^d \) which induce categorical equivalences
\[
X_v \simeq \prod_{s \in S} X_s \quad Y_v \simeq \prod_{s \in S} Y_s.
\]
Let \( \text{Fun}^v_{S^d}(X, Y) \) denote the full subcategory of \( \text{Fun}_{S^d}(X, Y) \) spanned by those maps which carry \( p \)-coCartesian morphisms to \( q \)-coCartesian morphisms. Then the restriction functor
\[
\text{Fun}^v_{S^d}(X, Y) \to \text{Fun}_{S^d}(X \times_{S^d} S, Y \times_{S^d} S)
\]
is a trivial Kan fibration.

Proof. In view of Proposition T.4.3.2.15, it will suffice to prove the following:

(1) A functor \( F \in \text{Fun}_{S^d}(X, Y) \) belongs to \( \text{Fun}^v_{S^d}(X, Y) \) if and only if \( F \) is a \( q \)-right Kan extension of \( F|X \).

(2) Every map \( F_0 \in \text{Fun}_{S^d}(X \times_{S^d} S, Y \times_{S^d} S) \) can be extended to a map \( F \in \text{Fun}_{S^d}(X, Y) \) satisfying the equivalent conditions of (1).

To prove (1), consider an arbitrary object \( x \) of \( X_v \), and choose \( p \)-coCartesian morphisms \( f_s : x \to x_s \) to objects \( x_s \in X_s \) for \( s \in S \). We note that the inclusion \( \{ f_s \}_{s \in S} \to (X \times_{S^d} S)_{x} \) is right cofinal. It follows that a functor \( F \) as in (1) is a \( q \)-right Kan extension of \( F_0 \) at \( x \) if and only if the maps \( F(f_s) \) exhibit \( F(x) \) as a \( q \)-product of the objects \( F_0(x_s) \). This is equivalent to the requirement that each \( F(f_s) \) is \( q \)-coCartesian. This proves the “if” direction of (1); the converse follows from same argument together with the observation that every \( p \)-coCartesian morphism \( f : x \to x_s \) in \( X \) can be completed to a collection of \( p \)-coCartesian morphisms \( \{ f_{s'} : x \to x_{s'} \}_{s' \in S} \).

To prove (2), it suffices (by Lemma T.4.3.2.13) to show that for every \( x \in X_v \), the diagram \( (X \times_{S^d} S)_{x} \to Y \) induced by \( F_0 \) can be extended to a \( q \)-limit diagram covering the projection map \( (X \times_{S^d} S)_{x} \to S^d \). Let \( \{ f_s : x \to x_s \}_{s \in S} \) be as above. We must show that there exists an object \( y \in Y_v \) equipped with morphisms \( y \to F_0(x_s) \) for \( s \in S \), which exhibit \( y \) as a \( q \)-product of \( \{ F_0(x_s) \}_{s \in S} \). It suffices to choose \( y \) to be any preimage of \( \{ F_0(x_s) \}_{s \in S} \) under the equivalence \( Y_v \simeq \prod_{s \in S} Y_s \).
Lemma 2.4.4.5. Let $S$ be a finite set (regarded as a discrete simplicial set), let $n > 0$, and suppose we are given inner fibrations $p : X \to \Delta^n \star S$ and $q : Y \to \Delta^n \star S$. For every simplicial subset $K \subseteq \Delta^n$, let $X_K$ denote the fiber product $X \times_{\Delta^n \star S} (K \star S)$, and define $Y_K$ similarly. Assume that the maps $X_{\{n\}} \to S^d$ and $Y_{\{n\}} \to S^d$ satisfy the hypotheses of Lemma 2.4.4.4, and for $\{n\} \subset K$ define $\operatorname{Fun}'_{K \star S}(X_K, Y_K)$ to be the fiber product

$$\operatorname{Fun}_{K \star S}(X_K, Y_K) \times_{\operatorname{Fun}_{\{n\} \star S}(X_{\{n\}}, Y_{\{n\}})} \operatorname{Fun}_{\{n\} \star S}(X_{\{n\}}, Y_{\{n\}}).$$

Then the map

$$\theta : \operatorname{Fun}'_{\Delta^n \star S}(X, Y) \to \operatorname{Fun}'_{\partial \Delta^n \star S}(X_{\partial \Delta^n}, Y_{\partial \Delta^n})$$

is a trivial Kan fibration.

Proof. The proof proceeds by induction on $n$. We observe that $\theta$ is evidently a categorical fibration; to prove that it is a trivial Kan fibration, it will suffice to show that $\theta$ is a categorical equivalence. Let $\theta''$ denote the composition

$$\operatorname{Fun}_{\Delta^n \star S}(X, Y) \overset{\phi}{\to} \operatorname{Fun}'_{\Delta^n \star S}(X_{\partial \Delta^n}, Y_{\partial \Delta^n}) \overset{\theta'}{\to} \operatorname{Fun}_{\partial \Delta^n \star S}(X_{\partial \Delta^n}, Y_{\partial \Delta^n}).$$

By a two-out-of-three argument, it will suffice to show that $\theta'$ and $\theta''$ are trivial Kan fibrations. The map $\theta'$ is a pullback of the composition

$$\operatorname{Fun}_{K \star S}(X_K, Y_K) \overset{\phi}{\to} \operatorname{Fun}'_{\{n\} \star S}(X_{\{n\}}, Y_{\{n\}}) \overset{\theta'}{\to} \operatorname{Fun}_{S}(X, Y),$$

where $K = \Delta^{n-1} \coprod \{n\} \subseteq \Delta^n$. It follows from iterated application of the inductive hypothesis that $\phi$ is a trivial Kan fibration, and it follows from Lemma 2.4.4.4 that $\theta'$ is a trivial Kan fibration. Consequently, to complete the proof, it will suffice to show that $\theta''$ is a trivial Kan fibration. In view of Proposition T.4.3.2.15, it will suffice to prove the following:

1. A map $F \in \operatorname{Fun}_{\Delta^n \star S}(X, Y)$ is a $q$-right Kan extension of $F_0 = F|\Delta^{n-1}$ if and only if it belongs to $\operatorname{Fun}'_{\Delta^n \star S}(X, Y)$.

2. Every map $F_0 \in \operatorname{Fun}_{\Delta^n \star S}(X_{\partial \Delta^n}, Y_{\partial \Delta^n})$ admits an extension $F \in \operatorname{Fun}_{\Delta^n \star S}(X, Y)$ satisfying the equivalent conditions of (1).

These assertions follow exactly as in the proof of Lemma 2.4.4.4.}$

Lemma 2.4.4.6. Let $p : \mathcal{C} \to \Delta^n$ be a map of $\infty$-categories, let $0 < i < n$, and assume that for every object $X \in \mathcal{C}_{i-1}$ there exists a $p$-coCartesian morphism $f : X \to Y$, where $Y \in \mathcal{C}_i$. Then the inclusion $p^{-1}\Lambda^n_i \subseteq \mathcal{C}$ is a categorical equivalence.

Proof. We first treat the special case $i = 1$. The proof proceeds by induction on $n$. Let $S$ be the collection of all nondegenerate simplices in $\Delta^n$ which contain the vertices 0, 1, and at least one other vertex. For each $\sigma \in S$, let $\sigma'$ be the simplex obtained from $\sigma$ by removing the vertex 1. Choose an ordering $S = \{\sigma_1, \ldots, \sigma_m\}$ of $S$ where the dimensions of the simplices $\sigma_j$ are nonstrictly decreasing as a function of $i$ (so that $\sigma_1 = \Delta^n$). For $0 \leq j \leq m$, let $K_j$ denote the simplicial subset of $\Delta^n$ obtained by removing the simplices $\sigma_k$ and $\sigma'_k$ for $k \leq j$. If we let $n_j$ denote the dimension of $\sigma_j$, then we have a pushout diagram

$$\begin{align*}
\Lambda^{n_j}_{1} & \longrightarrow K_j \\
\downarrow & \\
\Delta^n & \longrightarrow K_{j-1}
\end{align*}$$

Applying the inductive hypothesis (and the left properness of the Joyal model structure), we deduce that the inclusion $K_j \times_{\Delta^n} \mathcal{C} \to K_{j-1} \times_{\Delta^n} \mathcal{C}$ is a categorical equivalence for $1 < j \leq m$. Combining these facts, we deduce that the map $K_m \times_{\Delta^n} \mathcal{C} \subseteq K_1 \times_{\Delta^n} \mathcal{C} \simeq p^{-1}\Lambda^n_1$ is a categorical equivalence. By a two-out-of-three
argument, we are reduced to proving that the inclusion $K_m \times_{\Delta^n} \mathcal{C} \to \mathcal{C}$ is a categorical equivalence. Let $q : \Delta^n \to \Delta^2$ be the map given on vertices by the formula

$$q(k) = \begin{cases} 
0 & \text{if } k = 0 \\
1 & \text{if } k = 1 \\
2 & \text{otherwise}
\end{cases}$$

and observe that $K_m = q^{-1} \Lambda_1^2$. We may therefore replace $p$ by $q \circ p$ and thereby reduce to the case $n = 2$.

Choose a map $h : \Delta^1 \times \mathcal{C}_0 \to \mathcal{C}$ which is a natural transformation from the identity map $\text{id}_{\mathcal{C}_0}$ to a functor $F : \mathcal{C}_0 \to \mathcal{C}_1$, such that $h$ carries $\Delta^1 \times \{X\}$ to a $p$-coCartesian morphism in $\mathcal{C}$ for each $X \in \mathcal{C}_0$. Let $D = p^{-1} \Delta\{1, 2\}$. The natural transformation $h$ induces maps $(\Delta^1 \times \mathcal{C}_0) \coprod_{\{1\} \times \mathcal{C}_0} \mathcal{C}_1 \to p^{-1} \Delta^{\{0,1\}}$ and $(\Delta^1 \times \mathcal{C}_0) \coprod_{\{1\} \times \mathcal{C}_0} D \to \mathcal{C}$, and it follows from Proposition T.3.2.2.7 that these maps are categorical equivalences. Consider the diagram

$$\xymatrix{ (\Delta^1 \times \mathcal{C}_0) \coprod_{\{1\} \times \mathcal{C}_0} \mathcal{C}_1 \ar[rr] \ar[dr] & & p^{-1} \Lambda_1^2 \ar[dr] \\
& p^{-1} \Delta_{i}^2 \ar[rr] & & \mathcal{C}. }$$

It follows from the above arguments (and the left properness of the Joyal model structure) that the diagonal maps are categorical equivalences, so that the horizontal map is a categorical equivalence by the two-out-of-three property. This completes the proof in the case $i = 1$.

We now treat the case $i > 1$. The proof again proceeds by induction on $n$. Let $q : \Delta^n \to \Delta^3$ be the map defined by the formula

$$q(k) = \begin{cases} 
0 & \text{if } k < i - 1 \\
1 & \text{if } k = i - 1 \\
2 & \text{if } k = i \\
3 & \text{otherwise}.
\end{cases}$$

Let $S$ denote the collection of all nondegenerate simplices $\sigma$ of $\Delta^n$ such that the restriction $q|\sigma$ is surjective. For each $\sigma \in S$, let $\sigma'$ denote the simplex obtained from $\sigma$ by deleting the vertex $i$. Choosing an ordering $S = \{\sigma_1, \ldots, \sigma_m\}$ of $S$ where the dimension of the simplex $\sigma_j$ is a nondecreasing function of $j$ (so that $\sigma_1 = \Delta^n$), and for $0 \leq j \leq m$ let $K_j$ be the simplicial subset of $\Delta^n$ obtained by deleting $\sigma_k$ and $\sigma'_k$ for $k \leq j$. If we let $n_j$ denote the dimension of $\sigma_j$, then we have pushout diagrams

$$\xymatrix{ \Lambda_{p}^{n_j} \ar[rr] \ar[d] & & K_j \ar[d] \\
\Delta^{n_j} \ar[rr] & & K_{j-1} }$$

where $1 < p < n_j$. Applying the inductive hypothesis and the left properness of the Joyal model structure, we deduce that $K_j \times_{\Delta^n} \mathcal{C} \to K_{j-1} \times_{\Delta^n} \mathcal{C}$ is a categorical equivalence for $1 < j \leq m$. It follows that the map $K_m \times_{\Delta^n} \mathcal{C} \to K_1 \times_{\Delta^n} \mathcal{C} = p^{-1} \Lambda_i^n$
is a categorical equivalence. To complete the proof, it will suffice to show that the inclusion \( K_m \times \Delta^n \rightarrow \mathcal{C} \) is a categorical equivalence. We observe that \( K_m = q^{-1} \Lambda_2^m \). We may therefore replace \( p \) by \( q \circ p \) and reduce to the case where \( n = 3 \) and \( i = 2 \).

Applying Lemma 3.1.2.4, we can factor the map \( p^{-1} \Lambda_2^3 \rightarrow \Delta^3 \) as a composition

\[
p^{-1} \Lambda_2^3 \xrightarrow{j} \mathcal{C}' \xrightarrow{g} \Delta^3,
\]

where \( \mathcal{C}' \) is an \( \infty \)-category and \( i \) is a categorical equivalence which induces an isomorphism \( p^{-1} \Lambda_2^3 \simeq p'^{-1} \Lambda_2^3 \). In particular, \( i \) is a trivial cofibration with respect to the Joyal model structure, so there exists a solution to the following lifting property:

\[
p^{-1} \Lambda_2^3 \xrightarrow{j} \mathcal{C}' \xrightarrow{g} \Delta^3.
\]

Since the map \( g \) induces an isomorphism \( \Lambda_2^3 \times \Delta^3 \rightarrow \Delta_3 \mathcal{C} \), it is a categorical equivalence (it is bijective on vertices and induces isomorphisms \( \text{Hom}_\mathcal{C}(x, y) \rightarrow \text{Hom}_\mathcal{C}(g(x), g(y)) \) for every pair of vertices \( x, y \in \mathcal{C} \), since \( \Lambda_2^3 \) contains every edge of \( \Delta^3 \)). It follows that \( j = g \circ i \) is a categorical equivalence as well, which completes the proof.

**Proof of Theorem 2.4.4.3.** Let \( \mathcal{E}^\otimes \) be an \( \infty \)-operad and let \( \mathcal{X} \) the full subcategory of \( \text{Fun}_{N(\mathfrak{Fin}_n)}(\mathcal{E}^\otimes \otimes \mathcal{D}^\otimes, \mathcal{E}^\otimes) \) spanned functors \( F \) which carry inert morphisms in \( \mathcal{E}^\otimes \otimes \mathcal{D}^\otimes \) to inert morphisms in \( \mathcal{E}^\otimes \), and define \( \mathcal{Y} \subseteq \text{Fun}_{N(\mathfrak{Fin}_n)}(\mathcal{E}^\otimes \times \mathcal{D}^\otimes, \mathcal{E}^\otimes) \) similarly. We will show that the restriction functor \( \mathcal{X} \rightarrow \mathcal{Y} \) is a trivial Kan fibration.

We now introduce a bit of terminology. Let \( \sigma \) be an \( n \)-simplex of \( (\mathcal{D}^\otimes)^{\otimes} \) given by a sequence of morphisms

\[
\sigma(0) \xrightarrow{\pi(1)} \sigma(1) \xrightarrow{\cdots} \sigma(n)
\]

and let

\[
\langle k_0 \rangle \xrightarrow{a(1)} \langle k_1 \rangle \xrightarrow{\cdots} \langle k_n \rangle
\]

be the underlying \( n \)-simplex of \( N(\mathfrak{Fin}_n) \). We will say that \( \sigma \) is \textit{quasidegenerate} at \( \pi(i) \) if the following condition holds: whenever we are given \( i_- < i \leq i_+ \) and a sequence of integers \( \{a_j \in \langle k_j \rangle \}_{i_- \leq j \leq i_+} \) satisfying \( a_j(a_{j-1}) = a_j \), the corresponding map \( \Delta^{\{i_-i_{-1}+\cdots+i_{j-1} \}} \rightarrow \mathcal{D}^\otimes \) factors through the quotient map \( \Delta^{\{i_-i_{-1}+\cdots+i_{j-1} \}} \rightarrow \Delta^{i_{-1}i_{-1}+\cdots+i_{j-1}} \) which identifies the vertices \( i \) and \( i-1 \). If \( n = 1 \), we will simply say that \( \sigma \) is \textit{quasidegenerate} if it is quasi-degenerate at \( \pi(1) \). We will say that \( \sigma \) is \textit{closed} if \( k_n = 1 \), and \textit{open} otherwise. If \( \sigma \) is closed, we define the \textit{tail length} of \( \sigma \) by \( t(\sigma) \). We define the \textit{break point} of a closed simplex \( \sigma \) to be smallest nonnegative integer \( m \) such that \( \sigma \) is quasi-degenerate at \( \pi(k) \) and \( \pi(k) \) is active for \( m < k \leq n - t(\sigma) \). We will denote the break point of \( \sigma \) by \( b(\sigma) \).

Let \( S = \bigsqcup_{0 \leq i \leq n} \langle k_i \rangle^\otimes \). We will say that an element \( j \in \langle k_i \rangle^\otimes \subseteq S \) is a \textit{leaf} if \( i = 0 \) or if \( j \) does not lie in the image of the map \( \alpha_i(i) \), and we will say that \( j \) is a \textit{root} if \( i = n \) or if \( \alpha(i+1)(j) = * \). We define the \textit{complexity} \( c(\sigma) \) of \( \sigma \) to be \( 2l - r \), where \( l \) is the number of leaves of \( \sigma \) and \( r \) is the number of roots of \( \sigma \). We will say that \( \sigma \) is \textit{flat} if it belongs to the image of the embedding \( N(\mathfrak{Fin}_n) \times \mathcal{D}^\otimes \rightarrow (\mathcal{D}^\otimes)^{\otimes} \). Note that if \( \sigma \) is closed and \( b(\sigma) = 0 \), then \( \sigma \) is flat.

We now partition the nondegenerate, nonflat simplices of \( (\mathcal{D}^\otimes)^{\otimes} \) into six groups:

\begin{itemize}
  \item[(A)] An \( n \)-dimensional nonflat nondegenerate simplex \( \sigma \) of \( (\mathcal{D}^\otimes)^{\otimes} \) belongs to \( A \) if \( \sigma \) is closed and the map \( \alpha(b(\sigma)) \) is not inert.
  \item[(A')] An \( n \)-dimensional nonflat nondegenerate simplex \( \sigma \) of \( (\mathcal{D}^\otimes)^{\otimes} \) belongs to \( A' \) if \( \sigma \) is closed, \( b(\sigma) < n - t(\sigma) \), and the map \( \alpha(b(\sigma)) \) is inert.
  \item[(B)] An \( n \)-dimensional nonflat nondegenerate simplex \( \sigma \) of \( (\mathcal{D}^\otimes)^{\otimes} \) belongs to \( B \) if \( \sigma \) is closed, \( b(\sigma) = n - t(\sigma) \), the map \( \alpha(b(\sigma)) \) is inert, and \( \sigma \) is not quasidegenerate at \( \pi(b(\sigma)) \).
\end{itemize}
(B') An n-dimensional nonflat nondegenerate simplex $\sigma$ of $(\mathcal{D}^\otimes)^{1!}$ belongs to $B$ if $\sigma$ is closed, $b(\sigma) = n - t(\sigma) < n$, the map $\alpha(b(\sigma))$ is inert, and $\sigma$ is quasidegenerate at $\alpha(b(\sigma))$.

(C) An n-dimensional nonflat nondegenerate simplex $\sigma$ of $(\mathcal{D}^\otimes)^{1!}$ belongs to $C$ if it is open.

(C') An n-dimensional nonflat nondegenerate simplex $\sigma$ of $(\mathcal{D}^\otimes)^{1!}$ belongs to $C'$ is it is closed, $b(\sigma) = n - t(\sigma) = n$, the map $\alpha(b(\sigma))$ is inert, and $\sigma$ is quasidegenerate at $\alpha(b(\sigma))$.

If $\sigma$ belongs to $A'$, $B'$, or $C'$, then we define the associate $a(\sigma)$ of $\sigma$ to be the face of $\sigma$ opposite the $b(\sigma)$th vertex. Note that $a(\sigma)$ belongs to $A$ if $\sigma \in A'$, $B$ if $\sigma \in B'$, and $C$ if $\sigma \in C'$. In this case, we will say that $\sigma$ is an associate of $a(\sigma)$. We note that every simplex belonging to $A$ or $B$ has a unique associate, while a simplex $\sigma$ of $C$ has precisely $k$ associates, where $\langle k \rangle$ is the image of the final vertex of $\sigma$ in $N(\mathcal{F})$.

Moreover, the associate of a simplex $\sigma$ has the same complexity as $\sigma$.

For each $n \geq 0$, let $K(n) \subseteq (\mathcal{D}^\otimes)^{1!}$ be the simplicial subset generated by those nondegenerate simplices which are either flat, have dimension $\leq n$, or have dimension $n + 1$ and belong to either $A'$, $B'$, or $C'$. We observe that $K(0)$ is generated by $\mathcal{D}^\otimes \times N(\mathcal{F})$ together with the collection of 1-simplices belonging to $C'$.

Let $\mathcal{X}(n)$ denote the full subcategory of $\text{Map}_{N(\mathcal{F})}(\mathcal{D}^\otimes \times N(\mathcal{F}), K(n), \mathcal{E}^\otimes)$ spanned by those maps $F$ with the following properties:

(i) The restriction of $F$ to $\mathcal{E}^\otimes \times \mathcal{D}^\otimes$ belongs to $\mathcal{Y}$.

(ii) Let $f$ be an edge of $\mathcal{E}^\otimes \times N(\mathcal{F})$, $K(0)$ whose image in $\mathcal{E}^\otimes$ is inert and whose image in $K(0)$ belongs to $C'$. Then $F(f)$ is an inert morphism in $\mathcal{E}^\otimes$.

To complete the proof, it will suffice to show that the restriction maps $\mathcal{X} \xrightarrow{\theta'} \mathcal{X}(0) \xrightarrow{\theta''} \mathcal{Y}$ are trivial Kan fibrations. For the map $\theta''$, this follows from repeated application of Lemma 2.4.4.4. To prove that $\theta'$ is a trivial Kan fibration, we define $\mathcal{X}(n) \subseteq \text{Map}_{N(\mathcal{F})}(\mathcal{E}^\otimes \times N(\mathcal{F}), K(n), \mathcal{E}^\otimes)$ to be the full subcategory spanned by those functors $F$ whose restriction to $\mathcal{E}^\otimes \times N(\mathcal{F})$, $K(0)$ belongs to $\mathcal{X}(0)$. We will prove the following:

(a) A functor $F \in \text{Fun}_{N(\mathcal{F})}(\mathcal{E}^\otimes \times \mathcal{D}^\otimes, \mathcal{E}^\otimes)$ carries inert morphisms to inert morphisms if and only if $F$ satisfies conditions (i) and (ii). Consequently, the $\infty$-category $\mathcal{X}$ can be identified with the inverse limit of the tower $\cdots \to \mathcal{X}(2) \to \mathcal{X}(1) \to \mathcal{X}(0)$.

(b) For $n > 0$, the restriction map $\mathcal{X}(n) \to \mathcal{X}(n - 1)$ is a trivial Kan fibration.

We first prove (a). The “only if” direction is obvious. For the converse, suppose that an object $F$ of $\text{Fun}_{N(\mathcal{F})}(\mathcal{E}^\otimes \times \mathcal{D}^\otimes, \mathcal{E}^\otimes)$ satisfies conditions (i) and (ii) above. We wish to prove that $F$ preserves inert morphisms. Let $f : X \to X'$ be an inert morphism in $\mathcal{E}^\otimes \times \mathcal{D}^\otimes$ covering the map $f_0 : \langle k_1, \ldots, k_m \rangle \to \langle k'_1, \ldots, k'_m \rangle$ in $N(\mathcal{F})^{1!}$; we wish to prove that $F(f)$ is an inert morphism in $\mathcal{E}^\otimes$. If $m' = k'_i = 1$, then $f_0$ factors as a composition of inert morphisms $\langle k_1, \ldots, k_m \rangle \xrightarrow{f'_i} \langle k_i \rangle \xrightarrow{f''_i} \langle 1 \rangle$ for some $i \in \langle m \rangle$, which we can lift to a factorization $f \simeq f'' - \sigma f'$ of $f$ where $f'$ is quasidegenerate. Condition (ii) guarantees that $F(f')$ is inert, and condition (i) guarantees that $F(f'')$ is inert. In the general case, we consider for each $j \in \langle k'_i \rangle$ an inert morphism $g_{i,j} : X' \to X''$ lifting the composite map $\langle (k'_1), \ldots, (k'_m) \rangle \to \langle (k'_i) \rangle \to \langle 1 \rangle$. 
The above argument shows that $F(g_{i,j})$ and $F(g_{i,j} \circ f)$ are inert morphisms in $\mathcal{E}^\otimes$. The argument of Remark 2.1.2.9 shows that $F(f)$ is inert, as desired.

We now prove (b). For each integer $c \geq 0$, let $K(n, c)$ denote the simplicial subset $K(n)$ spanned by those simplices which either belong to $K(n-1)$ or have complexity $\leq c$. Let $\mathcal{X}(n, c)$ denote the full subcategory of $\text{Fun}_{N(\mathcal{F}_{in}, \mathcal{F}))}(\mathcal{E}^\otimes \times N(\mathcal{F}_{in}, \mathcal{F}))K(n, c), \mathcal{E}^\otimes)$ spanned by those maps $F$ whose restriction to $K(0)$ satisfies conditions (i) and (ii). We have a tower of simplicial sets

$$\cdots \to \mathcal{X}(n, 2) \to \mathcal{X}(n, 1) \to \mathcal{X}(n, 0) \simeq \mathcal{X}(n - 1)$$

with whose inverse limit can be identified with $\mathcal{X}(n)$. It will therefore suffice to show that for each $c > 0$, the restriction map $\mathcal{X}(n, c) \to \mathcal{X}(n, c - 1)$ is a trivial Kan fibration.

We now further refine our filtration as follows. Let $K(n, c)_A$ denote the simplicial subset of $K(n, c)$ spanned by $K(n, c - 1)$ together with those simplices of $K(n, c)$ which belong to $A$ or $A'$ and let $K(n, c)_B$ denote the simplicial subset of $K(n, c)$ spanned by $K(n, c - 1)$ together with those simplices which belong to $A$, $A'$, $B$, or $B'$. Let $\mathcal{X}(n, c)_A$ denote the full subcategory of $\text{Fun}_{N(\mathcal{F}_{in}, \mathcal{F}))}(\mathcal{E}^\otimes \times N(\mathcal{F}_{in}, \mathcal{F}))K(n, c)_A, \mathcal{E}^\otimes)$ spanned by those maps $F$ satisfying (i) and (ii), and define $\mathcal{X}(n, c)_B$ similarly. To complete the proof, it will suffice to prove the following:

(A) The restriction map $\mathcal{X}(n, c)_A \to \mathcal{X}(n, c - 1)$ is a trivial Kan fibration. To prove this, it suffices to show that the inclusion $\mathcal{E}^\otimes \times N(\mathcal{F}_{in}, \mathcal{F}))K(n, c - 1) \to \mathcal{E}^\otimes \times N(\mathcal{F}_{in}, \mathcal{F}))K(n, c)_A$ is a categorical equivalence. Let $A_{n,c}$ denote the collection of all $n$-simplices belonging to $A$ having complexity $c$. Choose a well-ordering of $A_{n,c}$ with the following properties:

- If $\sigma, \sigma' \in A_{n,c}$ and $t(\sigma) < t(\sigma')$, then $\sigma < \sigma'$.
- If $\sigma, \sigma' \in A_{n,c}$, $t(\sigma) = t(\sigma')$, and $b(\sigma) < b(\sigma')$, then $\sigma < \sigma'$.

For each $\sigma \in A_{n,c}$, let $K(n, c)_{\leq \sigma}$ denote the simplicial subset of $K(n, c)$ generated by $K(n, c - 1)$, all simplices $\tau \leq \sigma$ in $A_{n,c}$, and all of the simplices in $A'$ which are associated to simplices of the form $\tau \leq \sigma$. Define $K(n, c)_{< \sigma}$ similarly. Using transfinite induction on $A_{n,c}$, we are reduced to proving that for each $\sigma \in A_{n,c}$, the inclusion

$$i : \mathcal{E}^\otimes \times N(\mathcal{F}_{in}, \mathcal{F}))K(n, c)_{< \sigma} \to \mathcal{E}^\otimes \times N(\mathcal{F}_{in}, \mathcal{F}))K(n, c)_{\leq \sigma}$$

is a categorical equivalence. Let $\sigma' : \Delta^{n+1} \to (\mathcal{D}^\otimes)^{\uparrow}i$ be the unique $(n + 1)$-simplex of $A'$ associated to $\sigma$. We observe that $\sigma'$ determines a pushout diagram

$$\begin{array}{ccc}
\Lambda_{b(\sigma')}^{n+1} & \to & K(n, c)_{< \sigma} \\
\downarrow & & \downarrow \\
\Delta^{n+1} & \to & K(n, c)_{\leq \sigma}.
\end{array}$$

Consequently, the map $i$ is a pushout of an inclusion

$$i' : \mathcal{E}^\otimes \times N(\mathcal{F}_{in}, \mathcal{F}))\Lambda_{b(\sigma')}^{n+1} \to \mathcal{E}^\otimes \times N(\mathcal{F}_{in}, \mathcal{F}))\Delta_{b(\sigma')}^{n+1}.$$ 

Since the Joyal model structure is left proper, it suffices to show that $i'$ is a categorical equivalence, which follows from Lemma 2.4.4.6.

(B) The map $\mathcal{X}(n, c)_B \to \mathcal{X}(n, c)_A$ is a trivial Kan fibration. To prove this, it suffices to show that the inclusion $\mathcal{E}^\otimes \times N(\mathcal{F}_{in}, \mathcal{F}))K(n, c)_A \subseteq \mathcal{E}^\otimes \times N(\mathcal{F}_{in}, \mathcal{F}))K(n, c)_B$ is a categorical equivalence of simplicial sets. Let $B_{n,c}$ denote the collection of all $n$-simplices belonging to $B$ having complexity $c$. Choose a well-ordering of $B_{n,c}$ such that the function $\sigma \mapsto t(\sigma)$ is nonstrictly decreasing. For each $\sigma \in B_{n,c}$, we let $K(n, c)_{\leq \sigma}$ be the simplicial subset of $K(n, c)$ generated by $K(n, c)_A$, those simplices $\tau$ of $B_{n,c}$
such that \( \tau \leq \sigma \), and those simplices of \( B' \) which are associated to \( \tau \leq \sigma \in B_{n,c} \). Let \( K(n, c)_{<\sigma} \) be defined similarly. Using an induction on \( B_{n,c} \), we can reduce to the problem of showing that each of the inclusions
\[
\mathcal{C}^\otimes \times_{N(\text{Fin}_\ast)} K(n, c)_{<\sigma} \to \mathcal{C}^\otimes \times_{N(\text{Fin}_\ast)} K(n, c)_{\leq \sigma}
\]
is a categorical equivalence. Let \( \sigma' : \Delta^{n+1} \to (\mathcal{D}^\otimes)^{\text{II}} \) be the unique \((n+1)\)-simplex of \( B' \) associated to \( \sigma \). We observe that \( \sigma' \) determines a pushout diagram
\[
\Lambda_{b(\sigma')}^{n+1} \longrightarrow K(n, c)_{<\sigma} \\
\downarrow \quad \downarrow \\
\Delta^{n+1} \longrightarrow K(n, c)_{\leq \sigma}.
\]
Consequently, the map \( i \) is a pushout of an inclusion
\[
i' : \mathcal{C}^\otimes \times_{N(\text{Fin}_\ast)} \Lambda_{b(\sigma')}^{n+1} \to \mathcal{C}^\otimes \times_{N(\text{Fin}_\ast)} \Delta_{b(\sigma')}^{n+1}.
\]
Since the Joyal model structure is left proper, it suffices to show that \( i' \) is a categorical equivalence, which follows from Lemma 2.4.4.6.

(C) The map \( \mathcal{X}(n, c) \to \mathcal{X}(n, c)_B \) is a trivial Kan fibration. To prove this, let \( C_{n,c} \) denote the subset of \( C \) consisting of \( n \)-dimensional simplices of complexity \( c \), and choose a well-ordering of \( C_{n,c} \). For each \( \sigma \in C_{n,c} \), let \( K(n, c)_{<\sigma} \) denote the simplicial subset of \( K(n, c) \) generated by \( K(n, c)_B \), those simplices \( \tau \in C_{n,c} \) such that \( \tau \leq \sigma \), and those simplices of \( C' \) which are associated to \( \tau \in C_{n,c} \) with \( \tau \leq \sigma \). Let \( \mathcal{X}(n, c)_{\leq \sigma} \) be the full subcategory of \( \text{Fun}_{N(\text{Fin}_\ast)}(\mathcal{C}^\otimes \times_{N(\text{Fin}_\ast)} K(n, c)_{\leq \sigma}, \mathcal{E}^\otimes) \) spanned by those maps \( F \) satisfying (i) and (ii). We define \( K(n, c)_{<\sigma} \) and \( \mathcal{X}(n, c)_{<\sigma} \) similarly. Using transfinite induction on \( C_{n,c} \), we are reduced to the problem of showing that for each \( \sigma \in C_{n,c} \), the map \( \psi : \mathcal{X}(n, c)_{\leq \sigma} \to \mathcal{X}(n, c)_{<\sigma} \) is a trivial Kan fibration.

Let \( \langle k \rangle \) denote the image of the final vertex of \( \sigma \) in \( \text{Fin}_\ast \). For \( 1 \leq i \leq k \), let \( \sigma_i \in C' \) denote the unique \((n+1)\)-simplex associated to \( \sigma \) such that \( \sigma_i \) carries \( \Delta^{(n,n+1)} \) to the morphism \( \rho \) in \( \text{Fin}_\ast \). The simplices \( \{\sigma_i\}_{1 \leq i \leq k} \) determine a map of simplicial sets \( \Delta^n \ast \langle k \rangle^\circ \to K(n, c)_{\leq \sigma} \). We have a pushout diagram of simplicial sets
\[
(\partial \Delta^n) \ast \langle k \rangle^\circ \longrightarrow K(n, c)_{<\sigma} \\
\downarrow \downarrow \\
\Delta^n \ast \langle k \rangle^\circ \longrightarrow K(n, c)_{\leq \sigma}.
\]
The map \( \psi \) fits into a pullback diagram
\[
\begin{array}{ccc}
\mathcal{E}(n, c)_{<\sigma} & \longrightarrow & \text{Fun}_{\Delta^n \ast \langle k \rangle^\circ}(\mathcal{C}^\otimes \times_{N(\text{Fin}_\ast)}(\Delta^n \ast \langle k \rangle^\circ), \mathcal{E}^\otimes \times_{N(\text{Fin}_\ast)}(\Delta^n \ast \langle k \rangle^\circ)) \\
\downarrow \quad \downarrow \\
\mathcal{E}(n, c)_{\leq \sigma} & \longrightarrow & \text{Fun}_{\Delta^n \ast \langle k \rangle^\circ}(\mathcal{C}^\otimes \times_{N(\text{Fin}_\ast)}(\partial \Delta^n \ast \langle k \rangle^\circ), \mathcal{E}^\otimes \times_{N(\text{Fin}_\ast)}(\partial \Delta^n \ast \langle k \rangle^\circ))
\end{array}
\]
where \( \psi' \) denotes the trivial Kan fibration of Lemma 2.4.4.5.
Chapter 3

Algebras and Modules over ∞-Operads

Let $\mathcal{O}$ be an $\infty$-operad and let $\mathcal{C}$ be a symmetric monoidal $\infty$-category. In §2.1, we introduced the definition of an $\mathcal{O}$-algebra object of $\mathcal{C}$ (that is, a map of $\infty$-operads from $\mathcal{O}$ to $\mathcal{C}$). The collection of $\mathcal{O}$-algebra objects of $\mathcal{C}$ is naturally organized into an $\infty$-category $\text{Alg}_\mathcal{O}(\mathcal{C})$. Our goal in this chapter is to study the $\infty$-category $\text{Alg}_\mathcal{O}(\mathcal{C})$ in more detail.

Our starting point is the observation that for every object $X \in \mathcal{O}$, evaluation at $X$ determines a forgetful functor $e : \text{Alg}_\mathcal{O}(\mathcal{C}) \to \mathcal{C}$. In §3.1, we will show that (under some mild hypotheses) the forgetful functor $e$ admits a left adjoint $\text{Free} : \mathcal{C} \to \text{Alg}_\mathcal{O}(\mathcal{C})$. This left adjoint carries an object $C \in \mathcal{C}$ to the free algebra $\text{Free}(C)$ generated by $C$, which admits a relatively concrete description in terms of the tensor product on $\mathcal{C}$ and the structure of $\mathcal{O}$. The adjoint functors $\mathcal{C} \xleftarrow{e} \text{Alg}_\mathcal{O}(\mathcal{C})$ allow us to reduce many questions about $\text{Alg}_\mathcal{O}(\mathcal{C})$ to questions in the underlying $\infty$-category $\mathcal{C}$.

The second half of this chapter is devoted to the theory of modules over algebra objects of a symmetric monoidal $\infty$-category $\mathcal{C}$. Suppose we are given a commutative algebra object $A \in \text{CAlg}(\mathcal{C})$. We will define a new $\infty$-category $\text{Mod}_A(\mathcal{C})$, whose objects we refer to as $A$-module objects of $\mathcal{C}$. Under some mild hypotheses, one can show that the $\infty$-category $\text{Mod}_A(\mathcal{C})$ inherits a symmetric monoidal structure. More generally, we can attempt to associate to every algebra object $A \in \text{Alg}_\mathcal{O}(\mathcal{C})$ a fibration of $\infty$-operads $\text{Mod}_A^\mathcal{O}(\mathcal{C}) \to \mathcal{O}$. We will explain the construction of $\text{Mod}_A^\mathcal{O}(\mathcal{C})$ in §3.3. This construction will require an assumption on $\mathcal{O}$: namely, that it be a coherent $\infty$-operad (Definition 3.3.1.9). The collection of coherent $\infty$-operads includes most of the examples which are of interest to us in this book: for example, the commutative $\infty$-operad $\text{Comm}^\mathcal{O}$ of Example 2.1.1.18, the associative $\infty$-operad $\text{Ass}^\mathcal{O}$ we will study in Chapter 4, and the little cubes $\infty$-operads of Chapter 5 are all coherent. In §3.4, we will study the $\infty$-operads $\text{Mod}_A^\mathcal{O}(\mathcal{C})$ in greater depth. For example, we give criteria which guarantee that $\text{Mod}_A^\mathcal{O}(\mathcal{C})$ is a $\mathcal{O}$-monoidal $\infty$-category (in other words, that the tensor product on $A$-modules is well-defined), and study limits and colimits in the underlying $\infty$-category of $\text{Mod}_A^\mathcal{O}(\mathcal{C})$.

3.1 Free Algebras

Let $\mathcal{C}$ be a symmetric monoidal category. We let $\text{CAlg}(\mathcal{C})$ denote the category of commutative algebra objects of $\mathcal{C}$: that is, objects $A \in \mathcal{C}$ equipped with a multiplication $m : A \otimes A \to A$ which is commutative,
associative, and unital. There is an evident forgetful functor $\theta : \text{CAlg}(\mathcal{C}) \to \mathcal{C}$, which assigns to each commutative algebra its underlying object of $\mathcal{C}$. Assume that $\mathcal{C}$ admits small colimits, and that the tensor product operation $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves colimits separately in each variable. Then the forgetful functor $\theta$ admits a left adjoint. Moreover, this left adjoint admits an explicit description: it carries each object $C \in \mathcal{C}$ to the symmetric algebra

$$\text{Sym}^* C = \prod_n C^{\otimes n}/\Sigma_n.$$  

Here $\Sigma_n$ denotes the symmetric group on $n$ letters, which acts on the $n$th tensor power $C^{\otimes n}$.

In this section, we will describe an analogous theory of free algebras in the $\infty$-categorical context. Our discussion will be more general in several respects:

- We will replace the symmetric monoidal category $\mathcal{C}$ by a symmetric monoidal $\infty$-category $\mathcal{C}^\otimes$ (see Definition 2.0.0.7).

- The forgetful functor $\theta : \text{CAlg}(\mathcal{C}) \to \mathcal{C}$ can be identified with the restriction functor $\text{Alg}_{\text{Comm}}(\mathcal{C}) \to \text{Alg}_{\text{Triv}}(\mathcal{C})$ induced by the inclusion of $\infty$-operads $\text{Triv}^\otimes \subseteq \text{Comm}^\otimes$, where $\text{Triv}^\otimes$ is the trivial $\infty$-operad (Example 2.1.1.20) and $\text{Comm}^\otimes = \text{N}(\text{Fin}_n)$ is the commutative $\infty$-operad (Example 2.1.1.18). More generally, we can consider the restriction functor $\theta : \text{Alg}_O(\mathcal{C}) \to \text{Alg}_{O'}(\mathcal{C})$ induced by any map of $\infty$-operads $O^\otimes \to O'^\otimes$.

- If $O^\otimes \to O'^\otimes$ is a $O$-monoidal $\infty$-category, we can replace the $\infty$-categories $\text{Alg}_O(\mathcal{C})$ and $\text{Alg}_{O'}(\mathcal{C})$ with $\text{Alg}_{/O}(\mathcal{C})$ and $\text{Alg}_{/O'}(\mathcal{C})$, respectively.

We can now describe our main goal. Suppose that we are given a map of $\infty$-operads $f : O^\otimes \to O'^\otimes$ and a $O$-monoidal $\infty$-category $\mathcal{C}^\otimes \to O'^\otimes$. Composition with $f$ induces a forgetful functor $\theta : \text{Alg}_{/O}(\mathcal{C}) \to \text{Alg}_{/O'}(\mathcal{C})$. We will show that, under some mild hypotheses, the functor $\theta$ admits a left adjoint $F$. Moreover, if we assume that the $\infty$-operad $O'^\otimes$ is sufficiently simple (for example, if it is the trivial $\infty$-operad $\text{Triv}^\otimes$ of Example 2.1.1.20), then $F$ admits a very explicit description (see Proposition 3.1.3.13).

The construction of the functor $F$ uses a theory of operadic left Kan extensions, which we develop in §3.1.2. As in the non-operadic case, the theory of operadic left Kan extensions rests on a more basic theory of operadic colimit diagrams, which we discuss in §3.1.1. We will apply these ideas to the construction of free algebras in §3.1.3. Finally, in §3.1.4 we will establish a transitivity property of operadic left Kan extensions, which will play an important role in our discussion of tensor products of algebras in §5.3.3.

### 3.1.1 Operadic Colimit Diagrams

Let $\mathcal{C}$ be a symmetric monoidal category, and suppose we are given a sequence of maps

$$A_0 \to A_1 \to A_2 \to \cdots$$

in the category $\text{CAlg}(\mathcal{C})$ of commutative algebra objects of $\mathcal{C}$. If $\mathcal{C}$ admits sequential colimits, then we can define the colimit $A = \varinjlim_i A_i$ as an object of $\mathcal{C}$. In many cases, the object $A \in \mathcal{C}$ can also be regarded as a commutative algebra object of $\mathcal{C}$. There are evident maps

$$A \otimes A \simeq (\varinjlim_i A_i) \otimes (\varinjlim_j A_j) \overset{\theta}{\to} \varinjlim_i (A_i \otimes A_i) \simeq \varinjlim_i (A_i \otimes A_i) \to \varinjlim_i A_i \simeq A.$$  

If $\theta$ is an isomorphism, then we obtain a natural map $A \otimes A \to A$. We can guarantee that $\theta$ is an isomorphism by making an assumption like the following:

(*) The category $\mathcal{C}$ admits small colimits. Moreover, for every object $C \in \mathcal{C}$, the functor $\bullet \mapsto C \otimes \bullet$ preserves small colimits.
Condition (⋆) is satisfied in many cases. However, for many purposes it is unnecessarily restrictive. For example, it may be that \( \mathcal{C} \) does not admit colimits in general, but that a particular sequence of commutative algebras \( A_0 \to A_1 \to A_2 \to \cdots \) admits a colimit \( A \in \mathcal{C} \). In this case, it is convenient to replace (⋆) by the following local condition:

\((⋆')\) For every object \( C \in \mathcal{C} \), the induced maps \( A_i \otimes C \to A \otimes C \) exhibit \( A \otimes C \) as a colimit of the sequence

\[
A_0 \otimes C \to A_1 \otimes C \to A_2 \otimes C \to \cdots .
\]

Condition \((⋆')\) follows immediately from condition (⋆). Moreover, it is easy to see that condition \((⋆')\) guarantees that the map \( \theta \) is an isomorphism, which allows us to endow the colimit \( A \simeq \varinjlim A_i \) with the structure of a commutative algebra object of \( \mathcal{C} \). We will say that a compatible collection of maps \( A_i \to A \) exhibits \( A \) as an operadic colimit of the sequence \( A_i \) if condition (⋆) is satisfied. This implies in particular that \( A \) is a colimit \( \varinjlim A_i \) (take \( C \) to be the unit object of \( \mathcal{C} \) in (⋆)).

Our goal in this section is to study an analogue of condition \((⋆')\). Our setting will be more general in several respects:

(a) Rather than working with symmetric monoidal categories, we work with colored operads. Note that condition \((⋆')\) has an immediate generalization to the setting of colored operads: rather than requiring that \( A \otimes C \simeq \varinjlim A_i \otimes C \), we require that for every collection of objects \( \{C_j \in \mathcal{C} \}_{j \in J} \) and every object \( D \in \mathcal{C} \), the natural map

\[
\text{Mul}_C(\{A\} \cup \{C_j \}_{j \in J}, D) \to \varinjlim \text{Mul}_C(\{A_i\} \cup \{C_j \}_{j \in J}, D)
\]

is a bijection.

(b) We will work in the more general setting of \( \infty \)-operads, rather than ordinary colored operads.

(c) We will consider operadic colimits not just for sequences of objects in \( \mathcal{C} \), but for more general diagrams in the \( \infty \)-category \( \mathcal{C}^\otimes \).

(d) We will work not just with operadic colimit diagrams in a fixed \( \infty \)-operad \( \mathcal{O}^\otimes \), but also with operadic colimits relative to a fibration of \( \infty \)-operads \( \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) (for a discussion of relative colimits in the non-operadic setting, we refer the reader to §T.4.3.1).

We can now describe the contents of this section. Let \( q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads. We will introduce below the definition of an operadic \( q \)-colimit diagram \( K^p \to \mathcal{C}^\otimes \) (Definition 3.1.1.2). The remainder of this section is devoted to proving the basic facts about operadic \( q \)-colimit diagrams. In particular, we will prove an existence result for operadic \( q \)-colimit diagrams assuming that an appropriate analogue of condition (⋆) is satisfied (Corollary 3.1.1.21).

**Notation 3.1.1.1.** Let \( \mathcal{O}^\otimes \) be a generalized \( \infty \)-operad. We let \( \mathcal{O}^\otimes_{\text{act}} \) denote the subcategory of \( \mathcal{O}^\otimes \) spanned by those morphisms whose images in \( \text{N}(\mathcal{F}_{\text{Fin}*}) \) are active.

**Definition 3.1.1.2.** Let \( \mathcal{O}^\otimes \) be an \( \infty \)-operad and let \( p : K \to \mathcal{O}^\otimes \) be a diagram. We let \( \mathcal{O}_{p/} \) denote the \( \infty \)-category \( \mathcal{O} \times_{\mathcal{O}^\otimes} \mathcal{O}_{p/}^\otimes \). If \( p \) factors through \( \mathcal{O}^\otimes_{\text{act}} \), we let \( \mathcal{O}_{p/}^{\text{act}} \subseteq \mathcal{O}_{p/} \) denote the \( \infty \)-category \( \mathcal{O} \times_{\mathcal{O}^\otimes_{\text{act}}} (\mathcal{O}^\otimes_{\text{act}})^{p/} \).

Let \( q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads, let \( \bar{p} : K^\bar{p} \to \mathcal{O}_{\bar{p}/}^{\text{act}} \) be a diagram, and let \( p = \bar{p}/K \). We will say that \( \bar{p} \) is a weak operadic \( q \)-colimit diagram if the evident map

\[
\psi : \bar{p}^{\text{act}}_{\bar{p}/} \to \bar{p}^{\text{act}}_{\bar{p}/} \times_{\mathcal{O}^\otimes_{\bar{p}/}} \mathcal{O}^\otimes_{\bar{p}/}
\]

is a trivial Kan fibration.
We say that an active diagram \( p : K \to \mathcal{E}_\oplus \) is an operadic \( q \)-colimit diagram if the composite functor

\[
K \xrightarrow{p} \mathcal{E}_\oplus \xrightarrow{\oplus} \mathcal{E}_\text{act} \xrightarrow{\ominus} \mathcal{O}_\text{act}
\]

is a weak operadic \( q \)-colimit diagram, for every object \( C \in \mathcal{E}_\oplus \) (here the functor \( \oplus \) is defined as in Remark 2.2.4.6).

**Warning 3.1.1.3.** Let \( q : \mathcal{E}_\oplus \to \mathcal{O}_\oplus \) be a fibration of \( \infty \)-operads. A \( q \)-colimit diagram \( K \triangleright \to \mathcal{E}_\text{act} \) need not be an operadic \( q \)-colimit diagram, and an operadic \( q \)-colimit diagram need not be a \( q \)-colimit diagram. However, these notions can be related in special cases: see Propositions 3.1.1.10 and 3.1.1.16 below.

**Remark 3.1.1.4.** Let \( q : \mathcal{E}_\oplus \to \mathcal{O}_\oplus \) be as in Definition 3.1.1.2, let \( p : \mathcal{E}_\text{act} \to \mathcal{O}_\text{act} \) be a weak operadic \( q \)-colimit diagram, and let \( L \to K \) be a left cofinal map of simplicial sets. Then the induced map \( L \to \mathcal{E}_\text{act} \) is a weak operadic \( q \)-colimit diagram.

**Remark 3.1.1.5.** The map \( \psi \) appearing in Definition 3.1.1.2 is always a left fibration (Proposition T.2.1.2.1); consequently, it is a trivial Kan fibration if and only if it is a categorical equivalence (Corollary T.2.4.4.6).

**Example 3.1.1.6.** Let \( q : \mathcal{E}_\oplus \to \mathcal{O}_\oplus \) be as in Definition 3.1.1.2, let \( K = \Delta^0 \), and suppose that \( p : K \to \mathcal{E}_\text{act} \) corresponds to an equivalence in \( \mathcal{E}_\oplus \). Then \( p \) is an operadic \( q \)-colimit diagram.

The remainder of this section is devoted to a series of results which are useful for working with operadic colimit diagrams.

**Proposition 3.1.1.7.** Let \( q : \mathcal{E}_\oplus \to \mathcal{O}_\oplus \) be a fibration of \( \infty \)-operads let \( p : \mathcal{E}_\text{act} \to \mathcal{O}_\text{act} \) be a diagram. The following conditions are equivalent:

1. The map \( p \) is a weak operadic \( q \)-colimit diagram.
2. For every \( n > 0 \) and every diagram

\[
\begin{array}{ccc}
K \times \partial \Delta^n & \xrightarrow{f_0} & \mathcal{E}_\text{act} \\
\downarrow^f & & \downarrow^q \\
K \times \Delta^n & \xrightarrow{T} & \mathcal{O}_\text{act}
\end{array}
\]

such that the restriction of \( f_0 \) to \( K \times \{0\} \) coincides with \( p \) and \( f_0(n) \in \mathcal{E} \), there exists a dotted arrow \( f \) as indicated above.

**Proof.** The implication (2) \( \Rightarrow \) (1) follows immediately from the definition. For the converse, suppose that (1) is satisfied. Let \( r : \Delta^n \times \Delta^1 \to \Delta^n \) be the map which is given on vertices by the formula

\[
r(i,j) = \begin{cases} 
  i & \text{if } j = 0 \\
  n & \text{if } j = 1.
\end{cases}
\]

Set

\[
X = \partial \Delta^n \coprod_{\Lambda_n^0 \times \{0\}} \Delta^n \coprod_{\Lambda_n^1 \times \{1\}} \Delta^n,
\]

and regard \( X \) as a simplicial subset of \( \Delta^n \times \Delta^1 \); we observe that \( r \) carries \( X \) into \( \partial \Delta^n \). Composing \( f_0 \) and \( T \) with \( r \), we obtain a diagram

\[
\begin{array}{ccc}
\Delta^n \times \Delta^1 & \xrightarrow{q_0} & (\mathcal{E}_\text{act})_{f_0[K]} \\
\downarrow^g & & \downarrow^q \\
\Delta^n \times \Delta^1 & \xrightarrow{q'} & (\mathcal{O}_\text{act})_{T[K]}.
\end{array}
\]
To complete the proof, it will suffice to show that we can supply the dotted arrow in this diagram (we can then obtain $f$ by restricting $g$ to $\Delta^n \times \{0\}$). To prove this, we define a sequence of simplicial subsets
\[ X = X(0) \subset X(1) \subset X(2) \subset \cdots \subset X(2n + 1) = \Delta^n \times \Delta^1 \]
and extend $g_0$ to a sequence of maps $g_i : X(i) \to (\mathcal{C}^{\otimes}_{\text{act}})_{f_0} K_i$ compatible with the projection $q'$. The analysis proceeds as follows:

(i) For $1 \leq i \leq n$, we let $X(i)$ be the simplicial subset of $\Delta^n \times \Delta^1$ generated by $X(i-1)$ and the $n$-simplex $\sigma : \Delta^n \to \Delta^n \times \Delta^1$ given on vertices by the formula
\[
\sigma(j) = \begin{cases} 
(j,0) & \text{if } j \leq n - i \\
(j-1,1) & \text{if } j > n - i.
\end{cases}
\]
We have a pushout diagram of simplicial sets
\[
\begin{array}{ccc}
\Lambda^n_{n-1} & \longrightarrow & X(i-1) \\
\downarrow & & \downarrow \\
\Delta^n & \longrightarrow & X(i).
\end{array}
\]
If $1 \leq i < n$, then the extension $g_i$ of $g_{i-1}$ exists because $q'$ is an inner fibration. If $i = n$, then the desired extension exists by virtue of assumption (1).

(ii) If $i = n + i'$ for $0 < i' \leq n + 1$, we let $X(i)$ be the simplicial subset of $\Delta^n \times \Delta^1$ generated by $X(i-1)$ and the $(n+1)$-simplex $\sigma : \Delta^{n+1} \to \Delta^n \times \Delta^1$ given on vertices by the formula
\[
\sigma(j) = \begin{cases} 
(j,0) & \text{if } j < i' \\
(j-1,1) & \text{if } j \geq i'.
\end{cases}
\]
We have a pushout diagram of simplicial sets
\[
\begin{array}{ccc}
\Lambda^{n+1}_{n-1} & \longrightarrow & X(i-1) \\
\downarrow & & \downarrow \\
\Delta^{n+1} & \longrightarrow & X(i).
\end{array}
\]
If $1 \leq i' \leq n$, then the extension $g_i$ of $g_{i-1}$ exists because $q'$ is an inner fibration. If $i = n + 1$, then the desired extension exists because $g_{i-1}$ carries $\Delta^{\{n,n+1\}}$ to an equivalence in $(\mathcal{C}^{\otimes}_{\text{act}})_{f_0} K_i$.

Proposition 3.1.1.8. Let $q : \mathcal{C}^{\otimes} \to \mathcal{O}^{\otimes}$ be a fibration of $\infty$-operads, and suppose we are given a finite collection $\{\widetilde{p}_i : K_i \to \mathcal{C}^{\otimes}_{\text{act}}\}_{i \in I}$ of operadic $q$-colimit diagrams. Let $K = \prod_{i \in I} K_i$, and let $\overline{p}$ denote the composition
\[
K^{\triangleright} \to \prod_{i \in I} K_i^{\triangleright} \to \prod_{i \in I} \mathcal{C}^{\otimes} \overset{\otimes_i}{\longrightarrow} \mathcal{C}^{\otimes}_{\text{act}}.
\]
Then $\overline{p}$ is an operadic $q$-colimit diagram.

The proof of Proposition 3.1.1.8 depends on the following lemma:
Lemma 3.1.1.9. Let \( q : C^\otimes \to O^\otimes \) be a fibration of \( \infty \)-operads, let \( p' : K_0 \times K_1^\circ \to C_\text{act}^\otimes \) be a map, and let \( p = p'|K_0 \times K_1 \). Suppose that, for each vertex \( v \) of \( K_0 \), the induced map \( p'_v : K_1^\circ \to C_\text{act}^\otimes \) is a weak operadic \( q \)-colimit diagram. Then the map

\[
\theta : C_\text{act}^\otimes \to C_\text{act}^\otimes \times C_\text{act}^\otimes / O_\text{act}^\otimes / q_{p'/p}^\otimes
\]

is a trivial Kan fibration.

Proof. For each simplicial subset \( A \subseteq K_0 \), let \( L_A \) denote the pushout \( (K_0 \times K_1) \coprod_{(A \times K_1)} (A \times K_1^\circ) \), and let \( p_A = p'|L_A \). For \( A' \subseteq A \), let \( \theta^A_{A'} \) denote the map

\[
\theta^A_{A'} : C_\text{act}^\otimes \to C_\text{act}^\otimes \times C_\text{act}^\otimes / O_\text{act}^\otimes / q_{pA'/pA}^\otimes.
\]

We will prove that each of the maps \( \theta^A_{A'} \) is a trivial Kan fibration. Taking \( A = K_0 \) and \( A' = \emptyset \), this will imply the desired result.

Working simplex-by-simplex on \( A \), we may assume without loss of generality that \( A \) is obtained from \( A' \) by adjoining a single nondegenerate \( n \)-simplex whose boundary already belongs to \( A' \). Replacing \( K_0 \) by \( A \), we may assume that \( K_0 = A = \Delta^n \) and \( A' = \partial \Delta^n \). Working by induction on \( n \), we may assume that the map \( \theta^A_{A'} \) is a trivial Kan fibration. Since the map \( \theta^A_{A'} \) is a left fibration (Proposition T.2.1.2.1), it is a trivial Kan fibration if and only if it is a categorical fibration (Corollary T.2.4.4.6). Since \( \theta^A_{A'} = \theta^A_{\emptyset} \circ \theta^A_{A'} \), we can use the two-out-of-three property to reduce to the problem of showing that \( \theta^A_{\emptyset} \) is a categorical equivalence. Since \( A = \Delta^n \), the inclusion \( \{n\} \subseteq A \) is left cofinal so that \( \theta^A_{\{n\}} \) is a trivial Kan fibration. It therefore suffices to show that \( \theta^A_{\emptyset} \) is a trivial Kan fibration, which follows from our assumption that each \( p'_v \) is a weak operadic \( q \)-colimit diagram.

\( \square \)

Proof of Proposition 3.1.1.8. If \( I \) is empty, the desired result follows from Example 3.1.1.6. If \( I \) is a singleton, the result is obvious. To handle the general case, we can use induction on the cardinality of \( I \) to reduce to the case where \( I \) consists of two elements. Let us therefore suppose that we are given operadic \( q \)-colimit diagrams \( \overline{p}_0 : K_0^\circ \to C^\otimes \) and \( \overline{p}_1 : K_1^\circ \to C^\otimes \); we wish to prove that the induced map \( \overline{p} : (K_0 \times K_1)^\circ \to C^\otimes \) is an operadic \( q \)-colimit diagram. Let \( X \in C^\otimes \); we must show that the composition

\[
(K_0 \times K_1)^\circ \to C^\otimes \xrightarrow{\otimes X} C^\otimes
\]

is a weak operadic \( q \)-colimit diagram. Replacing \( \overline{p}_0 \) by the composition

\[
K_0^\circ \to C^\otimes \xrightarrow{\otimes X} C^\otimes,
\]

we can reduce to the case where \( X \) is trivial; it will therefore suffice to prove that \( \overline{p} \) is a weak operadic \( q \)-colimit diagram.

Let \( L \) denote the simplicial set \( K_0 \times K_1^\circ \). We have a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
K & \to & L \\
\downarrow & & \downarrow \\
K^\circ & \to & K_0^\circ \times \{v\}
\end{array}
\]

where \( v \) denotes the cone point of \( K_1^\circ \). Let \( \overline{p}' \) denote the composition

\[
L^\circ \to K_0^\circ \times K_1^\circ \to C_\text{act}^\otimes \times C_\text{act}^\otimes / \to C_\text{act}^\otimes.
\]

Since \( \overline{p}_0 \) is an operadic \( q \)-colimit diagram, we deduce that \( \overline{p}'(K_0^\circ \times \{v\}) \) is a weak operadic \( q \)-colimit diagram. Since the inclusion \( K_0 \times \{v\} \subseteq L \) is left cofinal, we deduce that \( \overline{p}' \) is a weak operadic \( q \)-colimit diagram.
(Remark 3.1.1.4). The inclusion $K^\circ \subseteq L^p$ is left cofinal (since the cone point is left cofinal in both). Consequently, to prove that $\overline{p}$ is a weak operadic $q$-colimit diagram, it will suffice to show that the map

$$C^\text{act}_{p/} \to C^\text{act}_{p/} \times_{O^\text{act}_{qp/}} O^\text{act}_{q\overline{p}/}$$

is a trivial Kan fibration, where $p = \overline{p}|K$. Since $\overline{p}'$ is a weak operadic $q$-colimit diagram, we are reduced to proving that

$$C^\text{act}_{p/} \times_{O^\text{act}_{qp/}} O^\text{act}_{q\overline{p}/} \to C^\text{act}_{p/} \times_{O^\text{act}_{qp/}} O^\text{act}_{q\overline{p}/}$$

is a trivial Kan fibration, where $p' = p|L$. This map is a pullback of $C^\text{act}_{p/} \to C^\text{act}_{p/} \times_{O^\text{act}_{qp/}} O^\text{act}_{q\overline{p}/}$, which is a trivial Kan fibration by Lemma 3.1.1.9 (since $\overline{p}$ is an operadic $q$-colimit diagram).

\[\blacksquare\]

**Proposition 3.1.1.10.** Let $q : C^\circ \to O^\circ$ be a fibration of $\infty$-operads. Suppose we are given a finite collection of operadic $q$-colimit diagrams $\overline{p}_i : K^\circ \to C^\text{act}_{i}$, where each $\overline{p}_i$ carries the cone point of $K^\circ$ into $C \subseteq C^\circ$. Let $K = \coprod_{i \in I} K_i$, and let $\overline{p} : K^\circ \to C^\circ$ be defined as in Proposition 3.1.1.8. If each of the simplicial sets $K_i$ is weakly contractible, then $\overline{p}$ is a $q$-colimit diagram.

We will need a few preliminaries:

**Lemma 3.1.1.11.** Let $q : C^\circ \to O^\circ$ be a fibration of $\infty$-operads, let $X \in C^\circ$ be an object lying over $\langle n \rangle \in \text{Fin}_*$, and choose inert morphisms $f_i : X \to X_i$ in $C^\circ$ covering $\rho' : \langle n \rangle \to \langle 1 \rangle$ for $1 \leq i \leq n$. Then the maps $\{f_i : X \to X_i\}_{1 \leq i \leq n}$ determine a $q$-limit diagram $\chi : \langle n \rangle^\circ \to O^\circ$.

**Proof.** Let $p : O^\circ \to N(\text{Fin}_*)$ be the map which exhibits $O^\circ$ as an $\infty$-operad. Since each $q(f_i)$ is an inert morphism in $O^\circ$, we can invoke the definition of an $\infty$-operad to deduce that $q \circ \chi$ is a $p$-limit diagram in $O^\circ$. Similarly, we conclude that $\chi$ is a $p \circ q$-limit diagram in $C^\circ$. The desired result now follows from Proposition T.4.3.1.5. \[\blacksquare\]

**Lemma 3.1.1.12.** Let $q : C^\circ \to O^\circ$ be a fibration of $\infty$-operads, let $\overline{p} : K^\circ \to C^\circ$ be a diagram, and let $p = \overline{p}|K$. Then $\overline{p}$ is a $q$-colimit diagram if and only if the induced map $\phi_0 : C_{\overline{p}/} \to C_{p/} \times_{O^\circ} O_{q\overline{p}/}$ is a trivial Kan fibration.

**Proof.** The “only if” direction is obvious. To prove the converse, suppose that $\phi_0$ is a trivial Kan fibration, and consider the map $\phi : C_{\overline{p}/} \to C_{p/} \times_{O^\circ} O_{q\overline{p}/}$. We wish to prove that $\phi$ is a trivial Kan fibration. Since $\phi$ is a left fibration (Proposition T.2.1.2.1), it suffices to show that the fibers of $\phi$ are contractible (Lemma T.2.1.3.4). Let $X$ be an object in the codomain of $\phi$ having image $X \in C^\circ$ and image $\langle n \rangle \in \text{Fin}_*$. For $1 \leq i \leq n$, choose an inert morphism $X \to X_i$ in $C^\circ$ lying over $\rho' : \langle n \rangle \to \langle 1 \rangle$. Since the projection $O^\circ \times_{O^\circ} O_{q\overline{p}/} \to C_{q\overline{p}/}$ is a left fibration (Proposition T.2.1.2.1), we can lift each of these inert morphisms in an essentially unique way to a map $X \to X_i$. Using Lemma 3.1.1.11, we deduce that the fiber $\phi^{-1}(X)$ is homotopy equivalent to the product $\coprod_{1 \leq i \leq n} \phi^{-1}(X_i)$, and therefore contractible (since $\phi^{-1}(X_i) = \phi_0^{-1}(X_i)$ is a fiber of the trivial Kan fibration $\phi_0$ for $1 \leq i \leq n$), as desired. \[\blacksquare\]

**Proof of Proposition 3.1.1.10.** In view of Lemma 3.1.1.12, it will suffice to show that the map $\phi_0 : C_{\overline{p}/} \to C_{p/} \times_{O^\circ} O_{q\overline{p}/}$ is a trivial Kan fibration. Since $\phi_0$ is a left fibration (Proposition T.2.1.2.1), it will suffice to show that $\phi_0^{-1}\{X\}$ is contractible for each vertex $X \in C_{p/} \times_{O^\circ} O_{q\overline{p}/}$ (Lemma T.2.1.3.4). Such a vertex determines a map $\alpha : I_* \to \langle 1 \rangle$; let $I_0 = \alpha^{-1}\{1\} \subseteq I$. Let $K' = \coprod_{i \in I_0} K_i$, let $\overline{p}'$ denote the composite map

$$K'' \to \coprod_{i \in I_0} K^\circ_i \to \coprod_{i \in I_0} C^\circ \xrightarrow{\overline{p}} C^\circ,$$

and let $\overline{p}''$ denote the composition $K'' \to K'' \to \overline{p} \to C^\circ$. 

There is a canonical map $\mathcal{P} : \Delta^1 \times K^\triangleright \to \mathcal{C}^\triangleright$ which is an inert natural transformation from $\mathcal{P}$ to $\mathcal{P}'$. Let $p'' = \mathcal{P}'|K$ and $P = \mathcal{P}|\Delta^1 \times K$, so we have a commutative diagram

\[
\begin{array}{ccc}
\mathcal{C}_P/ & \xrightarrow{\phi_0} & \mathcal{C}_{p/} \times \mathcal{O}_{q\mathcal{P}/} \\
\downarrow & & \downarrow \\
\mathcal{C}_{\mathcal{P}/} & \xrightarrow{\psi'} & \mathcal{C}_{p/} \times \mathcal{O}_{q\mathcal{P}/} \\
\downarrow & & \downarrow \\
\mathcal{C}_{p''/} & \xrightarrow{\psi} & \mathcal{C}_{p''/} \times \mathcal{O}_{q\mathcal{P}/}
\end{array}
\]

which determines a homotopy equivalence $\phi_0^{-1}X$ with a fiber of the map $\psi : \mathcal{C}_p^\act \to \mathcal{C}_{p''/} \times \mathcal{O}_{q\mathcal{P}/}$. It will therefore suffice to show that the fibers of $\psi$ are contractible. Since $\psi$ is a left fibration (Proposition T.2.1.2.1), this is equivalent to the assertion that $\psi$ is a categorical equivalence (Corollary T.2.4.4.6).

Because the simplicial sets $\{K_i\}_{i \in I - I_0}$ are weakly contractible, the projection map $K \to K'$ is left cofinal. Consequently, we have a commutative diagram

\[
\begin{array}{ccc}
\mathcal{C}_p^\act & \xrightarrow{\psi'} & \mathcal{C}_{p''/} \times \mathcal{O}_{q\mathcal{P}/} \\
\downarrow & & \downarrow \\
\mathcal{C}_{p''/} & \xrightarrow{\psi} & \mathcal{C}_{p''/} \times \mathcal{O}_{q\mathcal{P}/}
\end{array}
\]

where the vertical maps are categorical equivalences. Using a two-out-of-three argument, we are reduced to proving that $\psi'$ is a categorical equivalence. We conclude by observing that Proposition 3.1.1.8 guarantees that $\mathcal{P}'$ is an operadic $q$-colimit diagram, so that $\psi'$ is a trivial Kan fibraton.

Proposition 3.1.1.13. Let $q : \mathcal{C}^\triangleright \to \mathcal{O}^\triangleright$ be a fibration of $\infty$-operads and let $K = \Delta^0$. The following conditions are equivalent:

1. The map $q$ is a coCartesian fibration of $\infty$-operads.
2. For every map $p : K \to \mathcal{C}_p^\act$ and every extension $\mathcal{P}_0 : \mathcal{C}_p^\act \to \mathcal{O}_{q\mathcal{P}/}$ of $q \circ p$ carrying the cone point of $K^\triangleright$ into $\mathcal{O}$, there exists an operadic $q$-colimit diagram $\mathcal{P} : K^\triangleright \to \mathcal{C}_p^\act$ which extends $p$ and lifts $\mathcal{P}_0$.

Lemma 3.1.1.14. Let $\mathcal{O}^\triangleright$ be an $\infty$-operad and let $q : \mathcal{C}^\triangleright \to \mathcal{O}^\triangleright$ be a $\mathcal{O}$-monoidal $\infty$-category. Let $\mathcal{P} : \Delta^1 \to \mathcal{C}_p^\act$ classify an active $q$-coCartesian morphism $X \to Y$ in $\mathcal{C}^\triangleright$. Then $\mathcal{P}$ is an operadic $q$-colimit diagram.

Proof. Let $Z \in \mathcal{C}^\triangleright$. Replacing $p$ by its composition with the functor $\mathcal{C}^\triangleright \xrightarrow{\otimes Z} \mathcal{C}^\triangleright$ (and using Remark 2.2.4.8), we can reduce to showing that $\mathcal{P}$ is a weak operadic $q$-colimit diagram, which is clear.

Proof of Proposition 3.1.1.13. To prove that (1) implies (2), we observe that we can take $\mathcal{P}$ to be a $q$-coCartesian lift of $\mathcal{P}_0$ (by virtue of Lemma 3.1.1.14). Conversely, suppose that (2) is satisfied. Choose an object $X \in \mathcal{C}^\triangleright$, let $X = q(X)$, and suppose we are given a morphism $\alpha : X \to Z$ in $\mathcal{O}^\triangleright$; we wish to prove that we can lift $\alpha$ to a $q$-coCartesian morphism $X \to Z$ in $\mathcal{C}^\triangleright$. Using Proposition 2.1.2.4, we can factor $\alpha$ as a composition $X \overset{\alpha'}{\to} Y \overset{\alpha''}{\to} Z$ where $\alpha'$ is inert and $\alpha''$ is active. Let $\alpha'_0$ denote the image of $\alpha'$ in $\mathcal{F}_{\text{In}_+}$, and choose an inert morphism $\overline{\alpha} : X \to \overline{Y}$ in $\mathcal{C}^\triangleright$ lifting $\alpha'_0$. Then $q(\overline{\alpha})$ is an inert lift of $\alpha'_0$, so we may assume without loss of generality that $\overline{\alpha}'$ lifts $\alpha'$. Proposition T.2.4.1.3 guarantees that $\overline{\alpha}'$ is $q$-coCartesian. Since the collection of $q$-coCartesian morphisms in $\mathcal{C}^\triangleright$ is stable under composition (Proposition T.2.4.1.7), we may replace $X$ by $\overline{Y}$ and thereby reduce to the case where the map $\alpha$ is active.
3.1. FREE ALGEBRAS

Let \langle n \rangle denote the image of \( Z \) in \( \mathcal{F}_{\text{fin}} \). Since \( \mathcal{C}^\oplus \) and \( \mathcal{C}^\otimes \) are \( \infty \)-operads, we can identify \( X \) with a concatenation \( \bigoplus_{1 \leq i \leq n} X_i \) and \( \alpha \) with \( \bigoplus_{1 \leq i \leq n} \alpha_i \), where each \( \alpha_i : X_i = q(X_i) \to Z_i \) is an active morphism in \( \mathcal{O}^\otimes \) where \( Z_i \) lies over \( (1) \in \mathcal{F}_{\text{fin}} \). Assumption (2) guarantees that each \( \alpha_i \) can be lifted to an operadic \( q \)-colimit diagram \( \bar{\alpha}_i : X_i \to Z_i \) in \( \mathcal{C}^\otimes \). It follows from Proposition 3.1.1.10 that the concatenation \( \bar{\alpha} = \bigoplus_{1 \leq i \leq n} \bar{\alpha}_i \) is \( q \)-coCartesian. The map \( q(\bar{\alpha}) \) is equivalent to \( \bigoplus_{1 \leq i \leq n} q(\bar{\alpha}_i) \simeq \alpha \). Since \( q \) is a categorical fibration, we can replace \( \bar{\alpha} \) by an equivalent morphism if necessary to guarantee that \( q(\bar{\alpha}) = \alpha \), which completes the proof of (1). \( \square \)

Our next two results, which are counterparts of Propositions T.4.3.1.9 and T.4.3.1.10, are useful for detecting the existence of operadic colimit diagrams:

**Proposition 3.1.1.15.** Let \( q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads, let \( K \) be a simplicial set, and let \( \overline{h} : \Delta^1 \times K^\oplus \to \mathcal{C}^\act_{\overline{h}_0/} \) be a natural transformation from \( \overline{h}_0 = \overline{h}|\{0\} \times K^\oplus \) to \( \overline{h}_1 = \overline{h}|\{1\} \times K^\oplus \). Suppose that

(a) For every vertex \( x \) of \( K^\oplus \), the restriction \( \overline{h}|\Delta^1 \times \{x\} \) is a \( q \)-coCartesian edge of \( \mathcal{C}^\otimes \).

(b) The composition \( \Delta^1 \times \{v\} \subseteq \Delta^1 \times K^\oplus \xrightarrow{\overline{h}} \mathcal{C}^\otimes \xrightarrow{\overline{h}} \mathcal{O}^\otimes \) is an equivalence in \( \mathcal{O}^\otimes \), where \( v \) denotes the cone point of \( K^\oplus \).

Then:

(1) The map \( \overline{h}_0 \) is a weak operadic \( q \)-colimit diagram if and only if \( \overline{h}_1 \) is a weak operadic \( q \)-colimit diagram.

(2) Assume that \( q \) is a coCartesian fibration. Then \( \overline{h}_0 \) is an operadic \( q \)-colimit diagram if and only if \( \overline{h}_1 \) is an operadic \( q \)-colimit diagram.

**Proof.** Assertion (2) follows from (1) and Remark 2.2.4.8 (after composing with the functor \( \mathcal{C}^\otimes \otimes X \to \mathcal{C}^\otimes \) determined by an arbitrary object \( X \in \mathcal{C}^\otimes \)). It will therefore suffice to prove (1). Let \( h = \overline{h}|\Delta^1 \times K \), \( h_0 = h|\{0\} \times K \), and \( h_1 = h|\{1\} \times K \). We have a commutative diagram

According to Remark 3.1.1.5, it suffices to show that the left vertical map is a categorical equivalence if and only if the right vertical map is a categorical equivalence. Because the inclusions \( \{1\} \times K \subseteq \Delta^1 \times K \) and \( \{1\} \times K^\oplus \subseteq \Delta^1 \times K^\oplus \) are right anodyne, the horizontal maps on the right are trivial fibrations. Using a diagram chase, we are reduced to proving that the maps \( \phi \) and \( \psi \) are categorical equivalences.

Let \( f : x \to y \) denote the morphism \( \mathcal{C}^\otimes \) obtained by restricting \( \overline{h} \) to the cone point of \( K^\oplus \). The map \( \phi \) fits into a commutative diagram

Since the inclusion of the cone point into \( K^\oplus \) is right anodyne, the vertical arrows are trivial fibrations. Moreover, hypotheses (1) and (2) guarantee that \( f \) is an equivalence in \( \mathcal{C}^\otimes \), so that the map \( e_{f/} \to e_{x/} \) is a trivial fibration. This proves that \( \phi \) is a categorical equivalence.

The map \( \psi \) factors as a composition

\[
\mathcal{C}_{h/} \times O_{q/} \to \mathcal{C}_{h/} \times O_{q/} \to \mathcal{C}_{h/} \times O_{q/} \to \mathcal{C}_{h/} \times O_{q/} \,
\]
To complete the proof, it will suffice to show that ψ′ and ψ″ are trivial fibrations of simplicial sets. We first observe that ψ′ is a pullback of the map $C^\text{act}_{q\mathcal{F}'} \to C^\text{act}_{q\mathcal{K}_0}$, which is a trivial Kan fibration (Proposition T.3.1.1.11). The map ψ″ is a pullback of the left fibration $\psi_0' : O^\text{act}_{q\mathcal{F}'} \to O^\text{act}_{q\mathcal{K}_0}$. It therefore suffices to show that ψ″ is a categorical equivalence. To prove this, we consider the diagram

\[
\begin{array}{c}
\psi''_0 \\
\downarrow \\
\psi''_1 \\
O^\text{act}_{q\mathcal{F}'} \\
\downarrow \\
O^\text{act}_{q\mathcal{F}'}/q(f) \\
\end{array}
\]

As above, we observe that the vertical arrows are trivial fibrations and that ψ″ is a trivial fibration (because the morphism $q(f)$ is an equivalence in $O^\text{simp}$). It follows that ψ″ is a categorical equivalence, as desired. □

In the case where $q : C^\text{op} \to O^\text{op}$ is a coCartesian fibration, Proposition 3.1.1.15 allows us to reduce the problem of testing whether a diagram $p : K^\text{op} \to C^\text{op}$ is an operadic $q$-colimit to the special case where $p$ factors through $C^\text{op}_x$, for some $X \in O^\text{op}$. In this case, we can apply the following criterion:

**Proposition 3.1.1.16.** Let $q : C^\text{op} \to O^\text{op}$ be a coCartesian fibration of $\infty$-operads, let $X \in O^\text{op}$ be an object, and let $p : K^\text{op} \to C^\text{op}_X$ be a diagram. The following conditions are equivalent:

1. The map $p$ is an operadic $q$-colimit diagram.
2. For every object $Y \in C^\text{op}$ with image $Y \in O^\text{op}$, every object $Z \in O^\text{op}$, and every active morphism $m : X \oplus Y \to Z$ in $O^\text{op}$, the composition

\[K^\text{op} \to C^\text{op}_X \oplus Y \to C^\text{op}_{X \oplus Y} \xrightarrow{m_1} C^\text{op}_Z\]

is a colimit diagram in the $\infty$-category $C^\text{op}_Z$.

**Example 3.1.1.17.** Let $q : C^\text{op} \to N(F_{\text{Fin}_*})$ exhibit $C$ as a symmetric monoidal $\infty$-category. Then a diagram $p : K^\text{op} \to C^\text{op}$ is an operadic $q$-colimit diagram if and only if, for every object $C \in C^\text{op}$, the induced map $K^\text{op} \to C^\text{op} \times C^\text{op} C \in C^\text{op}$ is a colimit diagram in $C$. More informally: an operadic colimit diagram in $C$ is a colimit diagram which remains a colimit diagram after tensoring with any object of $C$.

**Proof of Proposition 3.1.1.16.** Replacing $p$ by its image under the functor $C^\text{op} \overset{\text{op}}{\to} C^\text{op}$, we are reduced to proving the following pair of assertions:

1. The map $p$ is a weak operadic $q$-colimit diagram.
2. For every object $Z \in O^\text{op}$ and every active morphism $m : X \to Z$ in $O^\text{op}$, the functor $m_1 : C^\text{op}_X \to C^\text{op}_Z$ carries $p$ to a colimit diagram in $C^\text{op}_Z$.

Assertion (1') is equivalent to the statement that the map $\theta : C^\text{act}_{p/} \to C^\text{act}_{p/} \times_{O^\text{act}_{q\mathcal{F}}} O^\text{act}_{q\mathcal{F}})$ is a trivial fibration of simplicial sets. Since $\theta$ is a left fibration (Proposition T.2.1.2.1), it will suffice to show that the fibers of $\theta$ are contractible. Consider an arbitrary vertex of $O^\text{act}_{q\mathcal{F}}$ corresponding to a diagram $t : K \star \Delta^1 \to O^\text{op}_{act}$. Since $K \star \Delta^1$ is categorically equivalent to $(K \star \{0\}) \coprod_{\{0\}} \Delta^1$ and $t|K \star \{0\}$ is constant, we may assume without loss of generality that $t$ factors as a composition

\[K \star \Delta^1 \to \Delta^1 \xrightarrow{m} O^\text{act}_{act} \]

Here $m : X \to Z$ can be identified with an active morphism in $O^\text{op}$. It will therefore suffice to show that the following assertions are equivalent, where $m : X \to Z$ is fixed:
(1') The map $\mathcal{C}_{\mathcal{P}}^{\text{act}} \times_{\mathcal{O}_{\mathcal{P}}} \{t\} \to \mathcal{C}_{\mathcal{P}}^{\text{act}} \times_{\mathcal{O}_{\mathcal{P}}} \{t_0\}$ is a homotopy equivalence, where $t \in \mathcal{O}_{\mathcal{P}}$ is determined by $m$ as above and $t_0$ is the image of $t$ in $\mathcal{O}_{\mathcal{P}}$.

(2') The map $m_1 : \mathcal{C}_X \to \mathcal{C}_Z$ carries $\mathcal{P}$ to a colimit diagram in $\mathcal{C}_Z$.

This equivalence results from the observation that the fibers of the maps $\mathcal{C}_{\mathcal{P}}^{\text{act}} \to \mathcal{O}_{\mathcal{P}}$ and $\mathcal{C}_{\mathcal{P}}^{\text{act}} \to \mathcal{O}_{\mathcal{P}}$ are equivalent to the fibers of the maps $\mathcal{C}_{m_1, \mathcal{P}}^{\text{act}} \to \mathcal{O}_{m_1, \mathcal{P}}$ and $\mathcal{C}_{m_1, \mathcal{P}}^{\text{act}} \to \mathcal{O}_{m_1, \mathcal{P}}$.

We now establish a general criterion for the existence of operadic colimit diagrams.

**Definition 3.1.1.18.** Let $q : \mathcal{C} \to \mathcal{O}$ be a coCartesian fibration of $\infty$-operads and let $K$ be a simplicial set. We will say that $q$ is compatible with $K$-indexed colimits if the following conditions are satisfied:

1. For every object $X \in \mathcal{O}$, the $\infty$-category $\mathcal{C}_X$ admits $K$-indexed colimits.
2. For every operation $f \in \text{Mul}_K((X_1)_{1 \leq i \leq n}, Y)$, the functor $\otimes_t : \prod_{1 \leq i \leq n} \mathcal{C}_{X_i} \to \mathcal{C}_Y$ of Remark 2.1.2.16 preserves $K$-indexed colimits separately in each variable.

**Variant 3.1.1.19.** If $\mathcal{X}$ is some collection of simplicial sets, we will say that a coCartesian fibration of $\infty$-operads $q : \mathcal{C} \to \mathcal{O}$ is compatible with $\mathcal{X}$-indexed colimits if it compatible with $K$-indexed colimits, for every $K \in \mathcal{X}$. For example, we may speak of $q$ being compatible with filtered colimits, sifted colimits, coproducts, or $\kappa$-small colimits where $\kappa$ is some regular cardinal.

**Proposition 3.1.1.20.** Let $K$ be a simplicial set, let $q : \mathcal{C} \to \mathcal{O}$ be a coCartesian fibration of $\infty$-operads which is compatible with $K$-indexed colimits, let $p : K \to \mathcal{C}_X$ be a diagram, and let $\mathcal{P}_0 : K^\circ \to \mathcal{O}^\circ$ be an extension of $qp$ which carries the cone point of $K^\circ$ to an object $X \in \mathcal{O}$. Then there exists an operadic $q$-colimit diagram $\mathcal{P} : K^\circ \to \mathcal{C}^\circ$ which extends $p$ and lifts $\mathcal{P}_0$.

**Proof.** Let $p_0 = qp$. The map $\mathcal{P}_0$ determines a natural transformation $\alpha : p_0 \to X$ of diagrams $K \to \mathcal{O}$, where $X$ denotes the constant diagram taking the value $X$. Choose a $q$-coCartesian natural transformation $\mathcal{P} : p \to p'$ lifting $\alpha$. Since $\mathcal{C}_X$ admits $K$-indexed colimits, we can extend $\mathcal{P}$ to a colimit diagram $\mathcal{P}' : K^\circ \to \mathcal{C}_X$. The compatibility of $q$ with $K$-indexed colimits and Proposition 3.1.1.16 imply that $\mathcal{P}'$ is an operadic $q$-colimit diagram. Let $C \in \mathcal{C}_X$ be the image under $\mathcal{P}'$ of the cone point of $K^\circ$, so we can regard $\mathcal{P}'$ as a diagram $K \to \mathcal{C}_X$ which lifts $p'$. Using the assumption that $\mathcal{C}^\circ \to \mathcal{C} \times_{\mathcal{O}^\circ} \mathcal{O}^\circ$ is a right fibration, we can choose a transformation $\mathcal{P} \to \mathcal{P}'$ lifting $\mathcal{P} : p \to p'$. It follows from Proposition 3.1.1.15 that $\mathcal{P}$ is an extension of $p$ with the desired properties.

**Corollary 3.1.1.21.** Let $q : \mathcal{C} \to \mathcal{O}$ be a fibration of $\infty$-operads and let $\kappa$ be a regular cardinal. The following conditions are equivalent:

1. The map $q$ is a coCartesian fibration of $\infty$-operads which is compatible with $\kappa$-small colimits.
2. For every $\kappa$-small simplicial set $K$ and every diagram

$$
\begin{array}{ccc}
K & \xrightarrow{p} & \mathcal{C}^\circ \\
\downarrow \mathcal{P} \downarrow \mathcal{P}' & & \downarrow \mathcal{P} \\
K^\circ & \xrightarrow{p_0} & \mathcal{O}^\circ
\end{array}
$$

such that $\mathcal{P}_0$ carries the cone point of $K^\circ$ into $\mathcal{O}$, there exists an extension $\mathcal{P}$ of $p$ as indicated in the diagram, which is an operadic $q$-colimit diagram.
Proof. The implication (1) ⇒ (2) is immediate from Proposition 3.1.1.20. Assume that (2) is satisfied. Taking \( K = \Delta^0 \) and applying Proposition 3.1.1.13, we deduce that \( q \) is a coCartesian fibration of \( \infty \)-operads. Applying (2) in the case where the map \( \overline{p}_0 \) takes some constant value \( X \in \mathcal{O} \), we deduce that every \( \kappa \)-small diagram \( K \to \mathcal{C}^\otimes_X \) can be extended to an operadic \( q \)-colimit diagram. This operadic \( q \)-colimit diagram is in particular a colimit diagram, so that \( \mathcal{C}^\otimes_X \) admits \( \kappa \)-small colimits. Moreover, the uniqueness properties of colimits show that every \( \kappa \)-small colimit diagram \( \overline{p} : K^\otimes \to \mathcal{C}^\otimes_X \) is a \( q \)-operadic colimit diagram. Combining this with the criterion of Proposition 3.1.1.16, we conclude that the \( q \) is compatible with \( \kappa \)-small colimits. \( \square \)

### 3.1.2 Operadic Left Kan Extensions

In §3.1.1, we introduced the theory of operadic colimit diagrams: this is an analogue of the usual theory of colimits to the setting of \( \infty \)-operads. The theory of colimits can be regarded as a special case of the theory of left Kan extensions: if \( K \) and \( \mathcal{C} \) are \( \infty \)-categories, then a map \( \overline{p} : K^\otimes \to \mathcal{C} \) is a colimit diagram if and only if \( \overline{p} \) is a left Kan extension of \( p = \overline{p}|K \). The theory of left Kan extensions also has a counterpart in the setting of \( \infty \)-operads, which we will call operadic left Kan extensions. Our goal in this section is to introduce this counterpart (Definition 3.1.2.2) and to prove a basic existence result (Theorem 3.1.2.3). The results of this section will play a crucial role in our discussion of free algebras in §3.1.3.

**Definition 3.1.2.1.** A correspondence of \( \infty \)-operads is a \( \Delta^1 \)-family of \( \infty \)-operads \( p : \mathcal{M}^\otimes \to N(\mathcal{F}\text{in}_{\ast}) \times \Delta^1 \). In this case, we will say that \( \mathcal{M}^\otimes \) is a correspondence from the \( \infty \)-operad \( \mathcal{A}^\otimes = \mathcal{M}^\otimes \times_{\Delta^1} \{0\} \) to the \( \infty \)-operad \( \mathcal{B}^\otimes = \mathcal{M}^\otimes \times_{\Delta^1} \{1\} \).

**Definition 3.1.2.2.** Let \( \mathcal{M}^\otimes \to N(\mathcal{F}\text{in}_{\ast}) \times \Delta^1 \) be a correspondence from an \( \infty \)-operad \( \mathcal{A}^\otimes \) to another \( \infty \)-operad \( \mathcal{B}^\otimes \); let \( q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads, and let \( \overline{F} : \mathcal{M}^\otimes \to \mathcal{C}^\otimes \) be a map of generalized \( \infty \)-operads. We will say that \( \overline{F} \) is an operadic \( q \)-left Kan extension of \( F = \overline{F}|\mathcal{A}^\otimes \) if the following condition is satisfied, for every object \( B \in \mathcal{B}^\otimes \):

\[
(*) \text{ Let } K = (\mathcal{M}^\otimes_{\text{act}})/B \times_{\mathcal{M}^\otimes} \mathcal{A}^\otimes. \text{ Then the composite map }

K^\otimes \to (\mathcal{M}^\otimes_{\text{act}})/B \to \mathcal{M}^\otimes \xrightarrow{\overline{F}} \mathcal{C}^\otimes

\]

is an operadic \( q \)-colimit diagram.

In the situation of Definition 3.1.2.2, the value of \( \overline{F} \) on any object \( B \in \mathcal{B} \) is determined up to equivalence by requirement \((*)\). Consequently, it is natural to expect that we can reconstruct \( \overline{F} \) from its restriction \( F = \overline{F}|\mathcal{A}^\otimes \) together with the composite map \( qF : \mathcal{M}^\otimes \to \mathcal{O}^\otimes \). More precisely, we have the following result concerning the existence and uniqueness of \( \overline{F} \):

**Theorem 3.1.2.3.** Let \( n \geq 1 \), let \( p : \mathcal{M}^\otimes \to N(\mathcal{F}\text{in}_{\ast}) \times \Delta^n \) be a \( \Delta^n \)-family of \( \infty \)-operads, and let \( q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads. Suppose we are given a commutative diagram of \( \infty \)-operad family maps

\[
\begin{array}{ccc}
\mathcal{M}^\otimes \times_{\Delta^n} \Lambda^n_0 & \xrightarrow{f_0} & \mathcal{C}^\otimes \\
\downarrow f & \nearrow q \\
\mathcal{M}^\otimes & \xrightarrow{g} & \mathcal{O}^\otimes.
\end{array}
\]

Then

\((A)\) Suppose that \( n = 1 \). The following conditions are equivalent:

\((a)\) There exists a dotted arrow \( f \) as indicated in the diagram which is an operadic \( q \)-left Kan extension of \( f_0 \) (in particular, such that \( f \) is a map of \( \infty \)-operad families).
3.1. FREE ALGEBRAS

(b) For every object $B \in M \times \Delta^* \{1\}$, the diagram

$$\left( M^\otimes_{act1} / B \times \Delta^* \{0\} \rightarrow M^\otimes \times \Delta^* \{0\} \stackrel{f_n}{\rightarrow} C^\otimes \right)$$

can be extended to an operadic $q$-colimit diagram lifting the map

$$\left( \left( M^\otimes_{act1} / B \times \Delta^* \{0\} \right)^{p} \rightarrow M^\otimes \times \Delta^* \{0\} \right).$$

(B) Suppose that $n > 1$, and that the restriction of $f_0$ to $M^\otimes \times \Delta^* \Delta^{0,1}$ is an operadic $q$-left Kan extension of $f_0|M^\otimes \times \Delta^* \{0\}$. Then there exists a dotted arrow $f$ as indicated in the diagram (automatically a map of generalized $\infty$-operads).

The remainder of this section is devoted to the proof of Theorem 3.1.2.3. Though the proof is somewhat complicated, the details of our argument will not be needed for subsequent applications; consequently, readers are invited to skip the remainder of this section and proceed directly to the applications which are presented in §3.1.3.

The proof of Theorem 3.1.2.3 will require the following Lemma.

Lemma 3.1.2.4. Suppose we are given an inner fibration of simplicial sets $p : \mathcal{C} \to \Lambda^3_2$ satisfying the following condition: for every object $X \in \mathcal{C}_1$, there exists a $p$-coCartesian morphism $f : X \to Y$ where $Y \in \mathcal{C}_2$. Then there exists a pullback diagram

$$\begin{array}{ccc}
\mathcal{C} & \longrightarrow & \mathcal{C}' \\
\downarrow^{p} & & \downarrow^{p'} \\
\Lambda^3_2 & \longrightarrow & \Delta^3
\end{array}$$

where $\mathcal{C}'$ is an $\infty$-category and the map $\mathcal{C} \hookrightarrow \mathcal{C}'$ is a categorical equivalence.

Proof. We will construct a sequence of categorical equivalences

$$\mathcal{C} = \mathcal{C}(0) \subseteq \mathcal{C}(1) \subseteq \cdots$$

in $(\text{Set}_\Delta)_{/\Delta^3}$ with the following properties:

(i) If $0 < i < n$ and $\Lambda^n_i \to \mathcal{C}(m)$ is a map, then the induced map $\Lambda^n_i \to \mathcal{C}(m + 1)$ can be extended to an $n$-simplex of $\mathcal{C}(m + 1)$.

(ii) For each $m \geq 0$, the inclusion $\mathcal{C} \subseteq \mathcal{C}(m) \times \Delta^3 \Lambda^3_2$ is an isomorphism of simplicial sets.

Our construction proceeds by induction on $m$. Assume that $\mathcal{C}(m)$ has been constructed, and let $A$ denote the collection of all maps $\alpha : \Lambda^n_i \to \mathcal{C}(m)$ for $0 < i < n$. We will prove that, for each $\alpha \in A$, there exists a categorical equivalence $\mathcal{C}(m) \subseteq \mathcal{C}(m, \alpha)$ in $(\text{Set}_\Delta)_{/\Delta^3}$ with the following properties:

(i') The composite map $\Lambda^n_i \to \mathcal{C}(m) \subseteq \mathcal{C}(m, \alpha)$ can be extended to an $n$-simplex of $\mathcal{C}(m, \alpha)$.

(ii') The map $\mathcal{C} \to \mathcal{C}(m, \alpha) \times \Delta^3 \Lambda^3_2$ is an isomorphism of simplicial sets.

Assuming that we can satisfy these conditions, we can complete the proof by defining $\mathcal{C}(m + 1)$ to be the amalgamation $\coprod_{\alpha \in A} \mathcal{C}(m, \alpha)$ in the category $(\text{Set}_\Delta)_{\text{act}(m)_{/\Delta^3}}$.

Suppose now that $\alpha : \Lambda^n_i \to \mathcal{C}(m)$ is given. If the composite map $\alpha_0 : \Lambda^n_i \to \mathcal{C}(m) \to \Delta^3$ factors through $\Lambda^3_2$, then we can use the assumption that $p$ is an inner fibration to extend $\alpha$ to an $n$-simplex of $\mathcal{C}$. In this case, we can satisfy requirements $(i')$ and $(ii')$ by setting $\mathcal{C}(m, \alpha) = \mathcal{C}(m)$. We may therefore assume without loss of generality that the image of $\alpha_0$ contains $\Delta^{[0,1,3]} \subseteq \Delta^3$. In particular, we see that $\alpha_0(0)$ and $\alpha_0(n) = 3$. 

\[ \text{end of page} \]
We observe that $\alpha_0$ extends uniquely to a map $\overline{\alpha}_0 : \Delta^n \to \Delta^3$. The pushout $\mathcal{C}(m) \coprod_{\Lambda^n} \Delta^n$ evidently satisfies condition (i') unless $\overline{\alpha}_0$ carries $\Delta^{\{0,\ldots,i-1,i+1,\ldots,n\}} \to \Delta^3$. If condition (i') is satisfied, we can set $\mathcal{C}(m, \alpha) = \mathcal{C}(m) \coprod_{\Lambda^n} \Delta^n$; otherwise, we have $\overline{\alpha}_0^{-1}(1) = \{i\}$.

Let $A = \overline{\alpha}_0^{-1}(0) \subseteq \Delta^n, B = \overline{\alpha}_0^{-1}(2) \subseteq \Delta^n$, and $C = \overline{\alpha}_0^{-1}(3) \subseteq \Delta^n$, so we have a canonical isomorphism $\Delta^n \simeq A \star \{x\} \star B \star C$ where $x$ corresponds to the $i$th vertex of $\Delta^n$. Let $\beta$ denote the restriction of $\alpha$ to $A \star \{x\} \star B$, and $\gamma$ the restriction of $\alpha$ to $\{x\} \star B \star C$. Let $X \in \mathcal{C}_1$ denote the image of $x$ in $\mathcal{C}_1$, and choose a $p$-coCartesian morphism $f : X \to Y$ in $\mathcal{C}$ where $Y \in \mathcal{C}_2$. Since $f$ is $p$-coCartesian, we can choose a map $\tau : \{x\} \star \{y\} \star B \star C \to \mathcal{C}$ which is compatible with $f$ and $\gamma$. Let $\tau_0 = \tau|\{x\} \star \{y\} \star B$, and choose a map $\beta : A \star \{x\} \star \{y\} \star B \to \mathcal{C}$ compatible with $\tau_0$ and $\beta$. The restrictions of $\beta$ and $\tau$ determine a map $\delta : (A \star \{y\}) \coprod B(\{y\} \star B \star C) \to \mathcal{C}$. Using the fact that $p$ is an inner fibration, we can extend $\delta$ to a map $\bar{\delta} : A \star \{y\} \star B \star C \to \mathcal{C}$. We define simplicial subsets

$$K_0 \subseteq K_1 \subseteq K_2 \subseteq A \star \{x\} \star \{y\} \star B \star C$$

as follows:

(a) The simplicial subset $K_0 \subseteq A \star \{x\} \star \{y\} \star B \star C$ is generated by $A \star \{x\} \star \{y\} \star B$ and $\{x\} \star \{y\} \star B \star C$.

(b) The simplicial subset $K_1 \subseteq A \star \{x\} \star \{y\} \star B \star C$ is generated by $K_0$ together with $\Lambda^n \subseteq A \star \{x\} \star B \star C$. Since the inclusions $\Lambda^n \subseteq \Delta^n$ and $(A \star \{x\} \star B) \coprod \{x\} \star B \star C) \subseteq A \star \{x\} \star B \star C$ are inner anodyne, the inclusion

$$i : (A \star \{x\} \star B) \coprod_{\{x\} \star B} ([x] \star B \star C) \subseteq \Lambda^n$$

is a categorical equivalence. The inclusion $K_0 \subseteq K_1$ is a pushout of $i$, and therefore also a categorical equivalence.

(c) The simplicial subset $K_2 \subseteq A \star \{x\} \star \{y\} \star B \star C$ is generated by $K_1$ together with $A \star \{y\} \star B \star C$. The inclusion $K_1 \subseteq K_2$ is a pushout of the inclusion $(A \star \{y\} \star B) \coprod (\{y\} \star B \star C) \subseteq A \star \{y\} \star B \star C$, and therefore a categorical equivalence.

The inclusion $K_0 \subseteq A \star \{x\} \star \{y\} \star B \star C$ is evidently a categorical equivalence. It follows from a two-out-of-three argument that the inclusion $K_2 \subseteq A \star \{x\} \star \{y\} \star B \star C$ is also a categorical equivalence. The maps $\delta, \beta, \tau$, and $\alpha$ determine a map $K_2 \to \mathcal{C}(m)$. We now define $\mathcal{C}(m, \alpha)$ to be the pushout $\mathcal{C}(m) \coprod_{K_2} (A \star \{x\} \star \{y\} \star B \star C)$. It is not difficult to verify that $\mathcal{C}(m, \alpha)$ has the desired properties.

**Lemma 3.1.2.5.** Let $\mathcal{C}$ be an $\infty$-category containing a full subcategory $\mathcal{C}^0$, and let $\sigma : \Delta^n \to \mathcal{C}$ be a nondegenerate simplex which does not intersect $\mathcal{C}^0$. Let $K \subseteq \mathcal{C} \subseteq \mathcal{C}$ be the simplicial subset spanned by those vertices $\tau : \Delta^m \to \mathcal{C}$ with the following property:

(*) There exists a map $\Delta^m \to \Delta^1$ such that $\tau_0 = \tau|(\Delta^m \times_{\Delta^1} \{0\})$ factors through $\mathcal{C}^0$ and $\tau_1 = \tau|(\Delta^m \times_{\Delta^1} \{1\})$ factors through $\sigma$.

Let $K_0$ be the simplicial subset of $K$ spanned by those simplices $\tau$ for which there exists a decomposition as in (*), where $\tau_1$ factors through $\partial : \partial \Delta^n \to \mathcal{C}$. Let $\mathcal{C}_/\sigma = \mathcal{C}^0 \times_{\mathcal{C}} \mathcal{C}_/\sigma$. Then the evident map

$$i : K_0 \coprod_{\mathcal{C}_/\sigma} (\mathcal{C}_/\sigma \times \Delta^n) \to K$$

is a trivial cofibration (with respect to the Joyal model structure).
3.1. FREE ALGEBRAS

Proof. Let $S$ be the collection of all simplices $\sigma' : \Delta^n' \to \mathcal{C}$ which factor as a composition $\Delta^n' \to \Delta^n \xrightarrow{\sigma} \mathcal{C}$, where the map $\Delta^n' \to \Delta^n$ is surjective. Choose an well-ordering of $S$ such that $\sigma' < \sigma''$ if the dimension of $\sigma'$ is smaller than the dimension of $\sigma''$ (so that $\sigma$ is the least element of $S$). Let $\alpha$ denote the order type of $S$, and for $\beta < \alpha$ let $\sigma'_\beta$ denote the corresponding element of $S$. For $\beta \leq \alpha$, let $K_\beta$ be the simplicial subset of $\mathcal{C}$ spanned by the nondegenerate simplices $\tau : \Delta^m \to \mathcal{C}$ for which there exists a map $\Delta^m \to \Delta^1$ such that $\tau_0$ factors through $\mathcal{C}^{\sigma'_0} = \epsilon$ and $\tau_1$ either factors through $\partial \sigma$ or is isomorphic to $\sigma'_\gamma$ for some $\gamma < \beta$ (here $\tau_0$ and $\tau_1$ are defined as in (*)). Then $K_\alpha = K$ and $K_1 = K_0 \coprod_{\mathcal{C}^{\sigma'_0}} \epsilon \Delta^m \star (\mathcal{C}^{\sigma'_0} \star \Delta^n)$. It will therefore suffice to show that the inclusion $K_1 \hookrightarrow K_\beta$ is a categorical equivalence for $1 \leq \beta \leq \alpha$. We proceed by induction on $\beta$.

The case $\beta = 1$ is trivial, and if $\beta$ is a nonzero limit ordinal then the assertion follows immediately from the inductive hypothesis since $K_\beta \simeq \varprojlim_{\gamma < \beta} K_\gamma$. It will therefore suffice to show that each of the inclusions $K_\beta \hookrightarrow K_{\beta+1}$ is a categorical equivalence. Let $\sigma' = \sigma'_\beta$, so that we can identify $\sigma'$ with a surjective map $\epsilon : \Delta^n' \to \Delta^n$.

Let $\mathcal{J}$ be the category whose objects are factorizations

$$
\Delta^n' \xrightarrow{\epsilon'} \Delta^n'' \xrightarrow{\epsilon''} \Delta^n
$$

of $\epsilon$ such that $\epsilon'$ is surjective. For each object $J = (\epsilon', \epsilon'') \in \mathcal{J}$ we let $\sigma'_J$ denote the composite map $\Delta^n'' \to \Delta^n \simeq \mathcal{C}$. Let $\mathcal{J}_0$ denote the full subcategory of $\mathcal{J}$ spanned by those objects where $n'' < n'$. There is an evident injective map $\mathcal{C}^{\sigma'_0}_J \to \mathcal{C}^{\sigma'_0}_{\epsilon''}$ for each $J \in \mathcal{J}_0$; let us denote the union of their images by $X \subseteq \mathcal{C}^{\sigma'_0}_{\epsilon''}$.

Unwinding the definitions, we note that the inclusion $K_\beta \hookrightarrow K_{\beta+1}$ is a pushout of the inclusion map $j : (X \star \Delta^n) \coprod_{X \star \partial \Delta^n} (\mathcal{C}^{\sigma'_0}_J \star \partial \Delta^n') \hookrightarrow \mathcal{C}^{\sigma'_0}_J \star \Delta^n'$.

It will therefore suffice to show that $j$ is categorical equivalence: that is, that the diagram

$$
\begin{array}{ccc}
X \star \partial \Delta^n & \xrightarrow{j} & X \star \Delta^n \\
\downarrow & & \downarrow \\
\mathcal{C}^{\sigma'_0}_J \star \partial \Delta^n & \rightarrow & \mathcal{C}^{\sigma'_0}_J \star \Delta^n
\end{array}
$$

is a homotopy pushout diagram (with respect to the Joyal model structure). In fact, we claim that the vertical maps are both categorical equivalences. To prove this, it suffices to show that the inclusion $X \hookrightarrow \mathcal{C}^{\sigma'_0}_J$ is a categorical equivalence. Note that $X$ is a colimit of the cofibrant diagram $\{\mathcal{C}^{\sigma'_0}_J\}_{J \in B_0^{\sigma''}}$. It will therefore suffice to show that $\mathcal{C}^{\sigma'_0}_J$ is a homotopy colimit of the diagram $\{\mathcal{C}^{\sigma'_0}_J\}_{J \in B_0^{\sigma''}}$. This diagram is essentially constant: for each $J \in \mathcal{J}_0$, the canonical map $\mathcal{C}^{\sigma'_0}_J \to \mathcal{C}^{\sigma'_0}_{\epsilon''}$ is a categorical equivalence, since for $C = \sigma_J(0) = \sigma'(0) \in \mathcal{C}$ we have a commutative diagram

$$
\begin{array}{ccc}
\mathcal{C}^{\sigma'_0}_J & \rightarrow & \mathcal{C}^{\sigma'_0}_{\epsilon''} \\
\downarrow & & \downarrow \\
\mathcal{C}^{\sigma'_0}_C & \rightarrow & \mathcal{C}^{\sigma'_0}_{\epsilon''}
\end{array}
$$

where the vertical maps are trivial Kan fibrations. Consequently, it will suffice to observe that the simplicial set $N(B_0)$ is weakly contractible. This is clear, since $B_0$ has a final object (given by the factorization $\epsilon = \text{id}_{\Delta^n} \circ \epsilon$).

Proof of Theorem 3.1.2.3. The implication $(a) \Rightarrow (b)$ in the case $(A)$ is obvious. Let us therefore assume either that $(b)$ is satisfied (if $n = 1$) or that $f_0(M^\otimes_1 \times \Delta^1 \{0, 1\})$ is an operadic $q$-left Kan extension of $f_0(M^\otimes_1 \times \Delta^1 \{0\})$ (if $n > 1$). To complete the proof, we need to construct a functor $f : M^\otimes \to \mathcal{C}^\otimes$ satisfying
some natural conditions. The construction is somewhat elaborate, and will require us to introduce some terminology.

Let \( \alpha \) be a morphism in \( N(\text{Fin}_n) \times \Delta^{(1, \ldots, n)} \), having image \( \alpha_0 : \langle m \rangle \rightarrow \langle n \rangle \) in \( N(\text{Fin}_n) \). We will say that \( \alpha \) is \textit{active} if the morphism \( \alpha_0 \) is active. We will say that \( \alpha \) is \textit{strongly inert} if the morphism \( \alpha_0 \) is inert, the image of \( \alpha \) in \( \Delta^{(1, \ldots, n)} \) is degenerate, and the injective map \( \alpha_0^{-1} : \langle n \rangle^o \rightarrow \langle m \rangle^o \) is order preserving. We will say that \( \alpha \) is \textit{neutral} if it is neither active nor strongly inert. Note that the collections of active and strongly inert morphisms are closed under composition. Moreover, every morphism \( \alpha \) can be written \textit{uniquely} as a composition \( \alpha'' \circ \alpha' \), where \( \alpha' \) is strongly inert and \( \alpha'' \) is active.

Let \( \sigma \) be an \( m \)-simplex of \( N(\text{Fin}_n) \times \Delta^{(1, \ldots, n)} \), corresponding to a chain of morphisms

\[
(\langle k_0 \rangle, e_0) \xrightarrow{\alpha_0} (\langle k_1 \rangle, e_1) \xrightarrow{\alpha_2} \cdots \xrightarrow{\alpha_m} (\langle k_m \rangle, e_m).
\]

We will say that \( \sigma \) is \textit{closed} if \( k_m = 1 \); otherwise we will say that \( \sigma \) is \textit{open}. We will say that \( \sigma \) is \textit{new} if the projection map \( \sigma \rightarrow \Delta^{(1, \ldots, n)} \) is surjective.

We now partition the collection of nondegenerate new simplices \( \sigma \) of \( N(\text{Fin}_n) \times \Delta^{(1, \ldots, n)} \) into five groups:

\( G'_{(1)} \): A nondegenerate new simplex \( \sigma \) of \( N(\text{Fin}_n) \times \Delta^{(1, \ldots, n)} \) belongs to \( G'_{(1)} \) if it is closed and each of the maps \( \alpha_\sigma(i) \) is active.

\( G'_{(2)} \): A nondegenerate new \( m \)-simplex \( \sigma \) of \( N(\text{Fin}_n) \times \Delta^{(1, \ldots, n)} \) belongs to \( G'_{(2)} \) if there exist integers \( 0 < j < k \leq m \) such that \( \alpha_\sigma(i) \) is strongly inert for \( i = j \), active for \( j < i \leq k \), and strongly inert for \( k < i \leq m \).

\( G'_{(3)} \): A nondegenerate new \( m \)-simplex \( \sigma \) of \( N(\text{Fin}_n) \times \Delta^{(1, \ldots, n)} \) belongs to \( G'_{(3)} \) if it is closed and there exist integers \( 0 < j < m \) such that \( \alpha_\sigma(i) \) is active for \( i = j \) and strongly inert for \( i > j \).

\( G'_{(4)} \): A nondegenerate new \( m \)-simplex \( \sigma \) of \( N(\text{Fin}_n) \times \Delta^{(1, \ldots, n)} \) belongs to \( G'_{(4)} \) if it is open and there exist integers \( 0 \leq j \leq m \) such that \( \alpha_\sigma(i) \) is active for \( i = j \) and strongly inert for \( i > j \).

If \( \sigma : \Delta^m \rightarrow N(\text{Fin}_n) \times \Delta^{(1, \ldots, n)} \) is a simplex belonging to \( G_{(2)} \), we define the \textit{associate} \( \sigma' \in G'_{(2)} \) of \( \sigma \) to be the \((m - 1)\)-simplex obtained by restricting \( \sigma \) to \( \Delta^{(0, \ldots, m-1)} \). If \( \sigma \) belongs to \( G_{(3)} \), we define its \textit{associate} \( \sigma' \in G'_{(3)} \) to be the \((m - 1)\)-simplex given by the restriction \( \sigma|\Delta^{(0, \ldots, j-1,j+1, \ldots, m)} \), where \( j \) is defined as above (note that \( j \) is uniquely determined). In either of these cases, we will also say that \( \sigma \) is an \textit{associate} of \( \sigma' \).

Note that every simplex of \( G'_{(2)} \) is the associate of a unique simplex belonging to \( G_{(2)} \), and that a simplex \( \sigma \) of \( G'_{(3)} \) with final vertex \( (\langle k \rangle, e) \) is associated to exactly \( k \) simplices of \( G_{(3)} \), obtained by concatenating \( \sigma \) with all possible strongly inert morphisms \( (\langle k \rangle, e) \rightarrow (\langle 1 \rangle, e) \).

For each integer \( m \geq 0 \), let \( F(m) \) denote simplicial subset of \( N(\text{Fin}_n) \times \Delta^{(1, \ldots, n)} \) spanned by the non-degenerate simplices which either belong to \( N(\text{Fin}_n) \times \partial \Delta^{(1, \ldots, n)} \), have dimension less than \( m \), or have dimension \( m \) and belong to \( G_{(2)} \) or \( G_{(3)} \). Let \( F'(m) \) be the simplicial subset of \( N(\text{Fin}_n) \times \Delta^n \) spanned by those simplices whose intersection with \( N(\text{Fin}_n) \times \Delta^{(1, \ldots, n)} \) belongs to \( F(m) \), and let \( M_{(m)}^\circ \) denote the inverse image of \( F(m) \) in \( M^\circ \). We observe that \( M_0^\circ = M^\circ \times \Delta^0 \). To complete the proof, it will suffice to show that \( f_0 : M_{(0)}^\circ \rightarrow \mathbb{C}^\circ \) can be extended to a sequence of maps \( f_m : M_{(m)}^\circ \rightarrow \mathbb{C}^\circ \) which fit into commutative diagrams

\[
\begin{array}{ccc}
M_{(m-1)}^\circ \\ f_{m-1} \downarrow \\
M_{(m)} \downarrow \leftarrow q \\
f_m \\
\end{array}
\]

and such that \( f_1 \) has the following special properties in the case \( n = 1 \):
(i) For each object $B \in \mathcal{M} \times \Delta_{n}\{1\}$, the map
\[(\mathcal{M}_{\mathrm{act}}^\otimes / B \times \Delta_{n} \{0\})^\triangleright \to \mathcal{M}_{(1)}^\otimes \xrightarrow{f_1} \mathcal{E}^\otimes\]
is an operadic $q$-colimit diagram.

(ii) For every inert morphism $e : M' \to M$ in $\mathcal{M}^\otimes \times \Delta_{n}\{1\}$ such that $M \in \mathcal{M} = \mathcal{M}_{(1)}^\otimes$, the functor $f_1$ carries $e$ to an inert morphism in $\mathcal{E}^\otimes$.

Fix $m > 0$, and suppose that $f_{m-1}$ has already been constructed. Our construction proceeds in several steps.

(1) Let $F'(m) \subseteq F(m)$ denote the simplicial subset of $F(m)$ spanned by those nondegenerate simplices belonging to either $F(m-1)$ or $G'_1$. Let $\mathcal{F}'(m)$ denote the simplicial subset of $N(\mathcal{F}_{\mathrm{fin}}) \times \Delta_{n}$ spanned by those simplices whose intersection with $N(\mathcal{F}_{\mathrm{fin}}) \times \Delta_{1}^{\ldots,n}$ belongs to $F(m)'$, and let $\mathcal{M}_{(m)}^\otimes$ denote the inverse image of $\mathcal{F}'(m)$ in $\mathcal{M}^\otimes$. We first prove the existence of a solution to the lifting problem
\[
\begin{array}{ccc}
\mathcal{M}_{(m-1)}^\otimes & \xrightarrow{f_{m-1}} & \mathcal{E}^\otimes \\
| & | & |
\downarrow q & \downarrow & \downarrow q \\
\mathcal{M}_{(m)}^\otimes & \xrightarrow{f_{m}} & \mathcal{O}^\otimes
\end{array}
\]
such that, when $m = n = 1$, the map $f_{m}$ satisfies condition (i).

Let $\{\sigma_{a}\}_{a \in A}$ be the collection of all nondegenerate simplices of $\mathcal{M}^\otimes \times \Delta_{n}\Delta_{1}^{\ldots,n}$ whose image in $N(\mathcal{F}_{\mathrm{fin}}) \times \Delta_{1}^{\ldots,n}$ has dimension $(m-1)$ and belongs to the class $G'_1$. Choose a well-ordering of the set $A$ such that the dimensions of the simplices $\sigma_{a}$ form a (nonstrictly) increasing function of $a$. For each $a \in A$, let $\mathcal{M}_{\leq a}^\otimes$ denote the simplicial subset of $\mathcal{M}^\otimes \times \Delta_{n}\Delta_{1}^{\ldots,n}$ together with those simplices whose intersection with $\mathcal{M}^\otimes \times \Delta_{n}\Delta_{1}^{\ldots,n}$ factors through $\sigma_{a'}$ for some $a' \leq a$, and define $\mathcal{M}_{\leq a}$ similarly. We construct a compatible family of maps $f_{\leq a} : \mathcal{M}_{\leq a}^\otimes \to \mathcal{E}^\otimes$ extending $f_{m-1}$, using transfinite induction on $a$. Assume that $f_{\leq a'}$ has been constructed for $a' < a$; these maps can be amalgamated to obtain a map $f_{\leq a} : \mathcal{M}_{\leq a}^\otimes \to \mathcal{E}^\otimes$. Let $X = \{0\} \times_{\Delta_{n}} \mathcal{M}_{/\sigma_{a}}$. Lemma 3.1.2.5 implies that we have a homotopy pushout diagram of simplicial sets
\[
\begin{array}{ccc}
X \times \partial \sigma_{a} & \to & \mathcal{M}_{\leq a}^\otimes \\
\downarrow & & \downarrow \\
X \times \sigma_{a} & \to & \mathcal{M}_{\leq a}^\otimes.
\end{array}
\]

It will therefore suffice to extend the composition
\[
g_0 : X \times \partial \sigma_{a} \to \mathcal{M}_{\leq a}^\otimes \xrightarrow{f_{\leq a}} \mathcal{E}^\otimes
\]
to a map $g : X \times \sigma_{a} \to \mathcal{E}^\otimes$ which is compatible with the projection to $\mathcal{O}^\otimes$.

We first treat the special case where the simplex $\sigma_{a}$ is zero-dimensional (in which case we must have $m = n = 1$). We can identify $\sigma_{a}$ with an object $B \in \mathcal{M}^\otimes$. Let $X_{0} = (\mathcal{M}_{\mathrm{act}}^\otimes / B \times \Delta_{n} \{0\}) \subseteq X$. Using assumption (b), we can choose a map $g_{1} : X_{0}^\otimes \to \mathcal{E}^\otimes$ compatible with the projection to $\mathcal{O}^\otimes$ which is an operadic $q$-colimit diagram. We note that $X_{0}$ is a localization of $X$ so that the inclusion $X_{0} \subseteq X$ is left cofinal; it follows that $g_{1}$ can be extended to a map $X^\otimes \to \mathcal{E}^\otimes$ with the desired properties. Note that our particular construction of $g$ guarantees that the map $f_{m}$ will satisfy condition (i).
Now suppose that \( \sigma_a \) is a simplex of positive dimension. We again let \( X_0 \) denote the simplicial subset of \( X \) spanned by those vertices of \( X \) which correspond to diagrams \( \sigma_a^0 \to \mathcal{C}^\otimes \) which project to a sequence of active morphisms in \( N(\mathcal{F}\text{in}_*) \). The inclusion \( X_0 \subseteq X \) admits a left adjoint and is therefore left cofinal; it follows that the induced map \( \mathcal{C}^\otimes_{(f_0|X)} / \to \mathcal{C}^\otimes_{(f_0|X_0)} / \times \mathcal{O}^\otimes_{(f_0|X_0)} / \mathcal{O}^\otimes_{(f_0|X)} / \) is a trivial Kan fibration. It therefore suffices to show that the restriction \( g'_0 = g_0|X_0 \ast \partial \sigma_a \) can be extended to a map \( g' : X_0 \ast \sigma_a \to \mathcal{C}^\otimes \) compatible with the projection to \( \mathcal{O}^\otimes \). In view of Proposition 3.1.1.7, it will suffice to show that the restriction \( g_0|\{X_0 \ast \{ B \} \} \) is a operadic q-colimit diagram. Since the inclusion \( \{ B \} \subseteq \sigma_a \) is left anodyne, the projection map \( X_0 \to \{ 0 \} \times_{\Delta^n} (\mathcal{M}_{\text{act}}^\otimes)_/B \) is a trivial Kan fibration. It will therefore suffice to show that \( f_{m-1} \) induces an operadic q-colimit diagram \( \delta : \{ 0 \} \times_{\Delta^n} (\mathcal{M}_{\text{act}}^\otimes)_/B \to \mathcal{C}^\otimes \).

Let \( \langle p \rangle \) be the image of \( B \) in \( N(\mathcal{F}\text{in}_*) \). The desired result follows immediately from (i) if \( p = 1 \), so assume that \( p \neq 1 \). Then the image of \( \sigma_a \) in \( N(\mathcal{F}\text{in}_*) \) has dimension \( \geq 1 \), so that \( m \geq 2 \) and therefore \( f_{m-1} \) is defined on \( \mathcal{M}_{\text{act}}^\otimes \). For \( 1 \leq i \leq p \), choose an inert morphism \( B \to B_i \) in \( \mathcal{B}^\otimes \) covering the map \( \rho^i : \langle p \rangle \to \{ 1 \} \), and let \( \delta_i : \{ 0 \} \times (\mathcal{M}_{\text{act}}^\otimes)_/B_i \to \mathcal{C}^\otimes \) be the map induced by \( f_{m-1} \). Condition (i) guarantees that each \( \delta_i \) is an operadic q-colimit diagram. Using the fact that \( \mathcal{M}^\otimes \) is a \( \Delta^n \)-family of \( \infty \)-operads, we deduce that the maps \( B \to B_i \) induce an equivalence

\[
\{ 0 \} \times_{\Delta^n} (\mathcal{M}_{\text{act}}^\otimes)_/B \simeq \prod_{1 \leq i \leq p} \{ 0 \} \times_{\Delta^n} (\mathcal{M}_{\text{act}}^\otimes)_/B_i.
\]

Using the fact that \( f_{m-1} \) satisfies (ii), we see that under this equivalence we can identify \( \delta \) with the diagram

\[
\prod_{1 \leq i \leq p} \{ 0 \} \times_{\Delta^n} (\mathcal{M}_{\text{act}}^\otimes)_/B_i \to \prod_{1 \leq i \leq p} (\mathcal{M}_{\text{act}}^\otimes)_/B_i \to \mathcal{C}^\otimes.
\]

Proposition 3.1.1.8 now implies that \( \delta \) is an operadic q-colimit diagram, as desired.

(2) Let \( F''(m) \) denote the simplicial subset of \( N(\mathcal{F}\text{in}_*) \times \Delta^{[1,\ldots,n]} \) spanned by \( F'(m) \) together with those \((m-1)\)-simplices \( \sigma \) belonging to \( G'_3 \) which have no associates (so that the final vertex of \( \sigma \) is equal to \((0,n)\)). Let \( F''(m) \) denote the collection of those simplices of \( N(\mathcal{F}\text{in}_*) \times \Delta^{[1,\ldots,n]} \) whose intersection with \( N(\mathcal{F}\text{in}_*) \times \Delta^{[1,\ldots,n]} \) belongs to \( F''(m) \), and let \( M'' \) denote the inverse image of \( F''(m) \) in \( \mathcal{M}^\otimes \).

We next show that \( f'_m \) can be extended to a map \( f''_m : M'' \to \mathcal{C}^\otimes \) (compatible with the projection to \( \mathcal{O}^\otimes \)).

We proceed as in the first step. Let \( \{ \sigma_a \}_{a \in A} \) be the collection of all nondegenerate simplices of \( \mathcal{M}^\otimes \times_{\Delta^n} \Delta^{[1,\ldots,n]} \) whose image in \( N(\mathcal{F}\text{in}_*) \times \Delta^{[1,\ldots,n]} \) has dimension \((m-1)\) and belongs to the class \( G'_3 \) and has no associates. Choose a well-ordering of the set \( A \) such that the dimensions of the simplices \( \sigma_a \) form a (nonstrictly) increasing function of \( a \). For each \( a \in A \), let \( M_{\leq a} \) denote the simplicial subset of \( \mathcal{M}^\otimes \) spanned by \( M_{\leq a}^\otimes \) together with those simplices whose intersection with \( \mathcal{M}^\otimes \times_{\Delta^n} \Delta^{[1,\ldots,n]} \) factors through \( \sigma_{a'} \) for some \( a' \leq a \), and define \( M_{< a} \) similarly. We construct a compatible family of maps \( f_{\leq a} : M_{\leq a} \to \mathcal{C}^\otimes \) extending \( f'_m \), using transfinite induction on \( a \). Assume that \( f_{\leq a'} \) has been constructed for \( a' < a \); these maps can be amalgamated to obtain a map \( f_{< a} : M_{< a} \to \mathcal{C}^\otimes \). Let \( X = \{ 0 \} \times_{\Delta^n} M_{\geq a}^\otimes \). Lemma 3.1.2.5 implies that we have a homotopy pushout diagram of simplicial sets

\[
X \ast \partial \sigma_a \longrightarrow M_{\leq a} \quad \xrightarrow{f_{\leq a}} \quad M_{\leq a} \longrightarrow M_{< a}.
\]

It will therefore suffice to extend the composition

\[
g_0 : X \ast \partial \sigma_a \longrightarrow M_{\leq a} \longrightarrow M_{< a} \longrightarrow \mathcal{C}^\otimes
\]

CHAPTER 3. ALGEBRAS AND MODULES OVER \( \infty \)-OPERADS
to a map \( g : X \ast \sigma_a \to \mathcal{C}^\otimes \) which is compatible with the projection to \( \mathcal{O}^\otimes \). In other words, it suffices to solve a lifting problem of the form

\[
\begin{array}{c}
\partial \sigma_a \\
\downarrow \\
\sigma_a \\
\downarrow \\
\mathcal{O}_X^\otimes \\
\downarrow \\
\mathcal{C}_X^\otimes .
\end{array}
\]

The existence of the desired lifting follows from the fact that the upper vertical map carries the final vertex of \( \sigma_a \) to a \( q \)-final vertex of \( \mathcal{C}^\otimes \).

(3) We now complete the induction by showing that \( f''_m \) can be extended to a map \( f_m : M_{(m)}^\otimes \to \mathcal{C}^\otimes \) (satisfying condition (ii) in the case \( m = n = 1 \)). The construction of this extension will require a somewhat intricate induction. Let \( \{ \sigma'_a \}_{a \in A} \) be the collection of all \((m-1)\)-simplices of \( N(\text{Fin}_n) \times \Delta^{1, \ldots, n} \) which belong to either \( G'_{(2)} \) or \( G'_{(3)} \) and admit at least one associate. Let \( a \in A \), and let \( \sigma \) denote an associate of the simplex \( \sigma'_a \), given by a sequence of morphisms

\[
(\langle k_0 \rangle, e_0) \xrightarrow{\alpha_{\sigma}(1)} (\langle k_1 \rangle, e_1) \xrightarrow{\alpha_{\sigma}(2)} \cdots \xrightarrow{\alpha_{\sigma}(m)} (\langle k_m \rangle, e_m).
\]

We define nonnegative integers \( u(a) \), \( v(a) \), and \( w(a) \) as follows:

- \( u(a) \) is the number of integers \( 1 \leq i \leq m \) such that \( \alpha_{\sigma}(i) \) is neutral.
- \( v(a) \) is the number of integers \( 1 \leq i \leq m \) such that \( \alpha_{\sigma}(i) \) is active.
- \( w(a) \) is the number of pairs of integers \( 1 \leq i < j \leq m \) such that \( \alpha_{\sigma}(i) \) is active and \( \alpha_{\sigma}(j) \) is strictly inert.

Note that these integers are independent of the choice of \( \sigma \) (in the case where \( \sigma'_a \in G'_{(3)} \), so that \( \sigma'_a \) has more than one associate). Choose a well-ordering on the set \( A \) with the following properties:

- If \( a, b \in A \) satisfy \( u(a) < u(b) \), then \( a < b \).
- If \( a, b \in A \) satisfy \( u(a) = u(b) \) and \( v(a) < v(b) \), then \( a < b \).
- Let \( a, b \in A \), and let \( \sigma \) and \( \tau \) denote associates of \( \sigma'_a \) and \( \sigma'_b \), respectively. If \( u(a) = u(b) \), \( v(a) = v(b) \), \( \sigma \) is closed, and \( \tau \) is open, then \( a < b \).
- Let \( a, b \in A \), and let \( \sigma \) and \( \tau \) denote associates of \( \sigma'_a \) and \( \sigma'_b \), respectively. If \( u(a) = u(b) \), \( v(a) = v(b) \), \( \sigma \) and \( \tau \) are either both open or both closed, and \( w(a) < w(b) \), then \( a < b \).

For each \( a \in A \), let \( F_{\leq a} \) denote the simplicial subset of \( F(m) \) given by the union of \( F''(m) \), all of the simplices \( \sigma'_b \) for \( b \leq a \), and all of the associates of the simplices \( \sigma'_b \) for \( b \leq a \). We let \( \overline{F}_{\leq a} \) denote the simplicial subset of \( N(\text{Fin}_n) \times \Delta^n \) spanned by those simplices whose intersection with \( N(\text{Fin}_n) \times \Delta^{1, \ldots, n} \) belongs to \( F_{\leq a} \), and \( M^\otimes_{\leq a} \) be the inverse image of \( \overline{F}_{\leq a} \) in \( \mathcal{M}^\otimes \). Define \( F_{< a}, \overline{F}_{< a}, \) and \( M^\otimes_{< a} \) similarly. We will construct \( f_m \) as the amalgamation of a compatible family of maps \( f_{\leq a} : M^\otimes_{\leq a} \to \mathcal{C}^\otimes \) extending \( f_{m-1} \). The construction proceeds by transfinite recursion. Assume that \( f_{\leq b} \) has been constructed for \( b < a \), so that the maps \( \{ f_{\leq b} \}_{b < a} \) determine a map \( f_{< a} : M^\otimes_{< a} \to \mathcal{C}^\otimes \). We wish to extend \( f_{< a} \) to a map \( f_{\leq a} \) (compatible with the projection to \( \mathcal{O}^\otimes \)). There are several cases to consider.

Suppose first that \( \sigma'_a \) belongs to \( G'_{(2)} \). In this case, we will prove the existence of the desired extension by showing that the inclusion \( M^\otimes_{< a} \hookrightarrow M^\otimes_{\leq a} \) is a categorical equivalence of simplicial sets, so that the existence of the map \( f_{\leq a} \) follows from the fact that \( q \) is a categorical fibration of simplicial sets. The simplex \( \sigma'_a \) has a unique associate, which we will denote by \( \sigma_a \). Note that \( \sigma'_a \) is a face of \( \sigma_a \), and all of
the other faces of \( \sigma_a \) belong to \( F_{<a} \). Let \( \Lambda \subseteq \sigma_a \) denote the inner horn opposite to the face \( \sigma'_a \). Let \( Y = \{0\} \times_{\Delta^n} (N(\text{Fin}_n) \times \Delta^n)/\sigma_a \), so that we have a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
Y \star \Lambda & \longrightarrow & \overline{F}_{<a} \\
\downarrow & & \downarrow \\
Y \star \sigma_a & \longrightarrow & \overline{F}_{\leq a}.
\end{array}
\]

It will therefore suffice to show that the inclusion

\[
(Y \star \Lambda) \times_{N(\text{Fin}_n) \times \Delta^n} M^\otimes \hookrightarrow (Y \star \sigma_a) \times_{N(\text{Fin}_n) \times \Delta^n} M^\otimes
\]

is a categorical equivalence. In fact, we will prove the following more general claim: for every map of simplicial sets \( \eta : Y \longrightarrow \overline{F}_{\leq a} \), the map

\[
\eta_{Y'} : (Y' \star \Lambda) \times_{N(\text{Fin}_n) \times \Delta^n} M^\otimes \hookrightarrow (Y' \star \sigma_a) \times_{N(\text{Fin}_n) \times \Delta^n} M^\otimes
\]

is a categorical equivalence. Since the construction \( Y' \mapsto \eta_{Y'} \) commutes with filtered colimits, we may assume that \( Y' \) has finitely many nondegenerate simplices. We proceed by induction on the dimension of \( Y' \), and on the number of nondegenerate simplices of \( Y' \). If \( Y' \) is empty, then the desired result follows immediately from Lemma 2.4.4.6. If \( Y' \) is nonempty, we have a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\partial \Delta^p & \longrightarrow & Y_0' \\
\downarrow & & \downarrow \\
\Delta^p & \longrightarrow & Y'.
\end{array}
\]

In this case, \( \eta_{Y'} \) factors as a composition

\[
(Y' \star \Lambda) \times_{N(\text{Fin}_n) \times \Delta^n} M^\otimes \xrightarrow{\eta'} ((Y' \star \Lambda) \amalg (Y' \star \sigma_a)) \times_{N(\text{Fin}_n) \times \Delta^n} M^\otimes
\]

\[
\xrightarrow{\eta''} (Y' \star \sigma_a) \times_{N(\text{Fin}_n) \times \Delta^n} M^\otimes
\]

The map \( \eta' \) is a pushout of \( \eta_{Y'} \), and therefore a categorical equivalence by the inductive hypothesis. The map \( \eta'' \) is a pushout of the inclusion

\[
(\Delta^p \star \Lambda) \amalg (\partial \Delta^p \star \sigma_a) \times_{N(\text{Fin}_n) \times \Delta^n} M^\otimes \hookrightarrow (\Delta^p \star \sigma_a) \times_{N(\text{Fin}_n) \times \Delta^n} M^\otimes,
\]

which is categorical equivalence by virtue of Lemma 2.4.4.6.

We now treat the case where \( \sigma'_a \in G_{(3)} \). Let \( \{\tau_b\}_{b \in B} \) be the collection of all nondegenerate simplices \( \tau \) of \( M^\otimes \) with the property that \( \tau \times_{\Delta^n} \Delta^{[1,\ldots,n]} \) maps surjectively to the simplex \( \sigma'_a \) of \( N(\text{Fin}_n) \times \Delta^n \). Choose a well-ordering of \( B \) such that the dimension of the simplex \( \tau_b \) is a (nonstrictly) increasing function of \( b \). For each \( b \in B \), let \( N_{<b} \subseteq M^\otimes \) denote the simplicial subset generated by \( M^\otimes_{\leq a} \) together with those simplices \( \tau : \Delta^p \longrightarrow M^\otimes \) such that for some \( p' < p \), the restriction \( \tau|\Delta^{[0,\ldots,p']} \) factors through a simplex \( \tau_{b'} \) for \( b' \leq b \), the map \( \tau(p') \longrightarrow \tau(p' + 1) \) is an inert morphism in \( D^\otimes \), and \( \tau|\Delta^{[p'+1,\ldots,p]} \) factors through \( D \). Define \( N_{\leq b} \) similarly. We will construction \( f_{<a} \) as the amalgamation of a compatible family of maps \( g_{<b} : N_{<b} \longrightarrow \mathcal{C}^\otimes \). The construction proceeds by transfinite induction on \( b \). Assume that \( g_{<b} \) has been constructed for \( b' < b \), so that the set of maps \( \{g_{<b'}\}_{b' < b} \) determines a map \( g_{<b} : N_{<b} \longrightarrow \mathcal{C}^\otimes \). We wish to show that there is a solution to the lifting problem

\[
\begin{array}{ccc}
N_{<b} & \longrightarrow & \mathcal{C}^\otimes \\
\downarrow g_{<b} & \swarrow \eta_{<b} \\
N_{\leq b} & \longrightarrow & \mathcal{O}^\otimes.
\end{array}
\]
3.1. FREE ALGEBRAS

The final vertex of $\tau_b$ is given by $((k), n)$ for some $k \geq 2$. For $1 \leq i \leq k$, we have a strongly inert morphism $((k), n) \to ((1), n)$. Taken together, these morphisms determine a map $\tau_b \ast \{1, \ldots, k\} \to N(\mathcal{F}\text{in}_k) \times \Delta^\infty$. Let $X = M^\circ \times N(\mathcal{F}\text{in}_k)(\tau_b \ast \{1, \ldots, k\})$. Note that $\tau_b$ lifts to a simplex $\tau_b$ in $X$. For $1 \leq i \leq k$ let $X_i$ denote the fiber of $X$ over the vertex $i \in \{1, \ldots, k\}$, let $X^0 = \bigcup_{1 \leq i \leq k} X_i$, and set $X^0_{\tau_b/} = X^0 \times_X X_{\tau_b/}$. Using Lemma 3.1.2.5, we obtain a homotopy pushout diagram

\[
\begin{array}{ccc}
\partial \tau_b \ast X^0_{\tau_b/} & \longrightarrow & N_{<b} \\
\downarrow & & \downarrow \\
\tau_b \ast X^0_{\tau_b/} & \longrightarrow & N_{\leq b}.
\end{array}
\]

According to Proposition T.A.2.3.1, it will suffice to solve the associated lifting problem

\[
\begin{array}{ccc}
\partial \tau_b \ast X^0_{\tau_b/} & \longrightarrow & C^\circ \\
\downarrow & & \downarrow \\
\tau_b \ast X^0_{\tau_b/} & \longrightarrow & O^\circ.
\end{array}
\]

Note that the $\infty$-category $X^0_{\tau_b/}$ decomposes naturally as a disjoint union $\coprod_{1 \leq i \leq k} X_i$, where $X_i = X_i \times_X X_{\tau_b/}$. Each of the $\infty$-categories $X_i$ has an initial object $B_i$, given by any map $\tau_b \ast \{D_i\} \to C^\circ$ which induces an inert morphism $D_b \to D_i$ covering $\rho^i : (k) \to (1)$. Let $h : X^0_{\tau_b/} \to C^\circ$ be the map induced by $g'_0$, and let $h'$ be the restriction of $h$ to the discrete simplicial set $X' = \{B_i\}_{1 \leq i \leq k}$. Since inclusion $X' \to X^0_{\tau_b/}$ is left anodyne, we have a trivial Kan fibration $C^\circ/h \to C^\circ/h' \times_{O^\circ/h} O^\circ$. We are therefore reduced to the problem of solving the a lifting problem of the form

\[
\begin{array}{ccc}
\partial \tau_b \ast X' & \longrightarrow & C^\circ \\
\downarrow & & \downarrow \\
\tau_b \ast X' & \longrightarrow & O^\circ.
\end{array}
\]

If the dimension of $\tau_b$ is positive, then it suffices to check that $g''_0$ carries $\{D_b\} \ast X'$ to a $q$-limit diagram in $C^\circ$. Let $q'$ denote the canonical map $O^\circ \to N(\mathcal{F}\text{in}_k)$. In view of Proposition T.A.3.1.5, it suffices to show that $g''_0$ carries $\{D_b\} \ast X'$ to a $(q' \circ q)$-limit diagram and that $q \circ g''_0$ carries $\{D_b\} \ast X'$ to a $q'$-limit diagram. The first of these assertions follows from $(ii)$ and from the fact that $C^\circ$ is an $\infty$-operad, and the second follows by the same argument (since $q$ is a map of $\infty$-operads).

It remains to treat the case where $\tau_b$ is zero dimensional (in which case we must have $m = n = 1$). Since $C^\circ$ is an $\infty$-operad, we can solve the lifting problem depicted in the diagram

\[
\begin{array}{ccc}
\partial \tau_b \ast X' & \longrightarrow & C^\circ \\
\downarrow & \Downarrow j & \Downarrow \circ q \\
\tau_b \ast X' & \longrightarrow & N(\mathcal{F}\text{in}_k)
\end{array}
\]

in such a way that $j$ carries edges of $\tau_b \ast X'$ to inert morphisms in $C^\circ$. Since $q$ is an $\infty$-operad map, it follows that $q \circ j$ has the same property. Since $O^\circ$ is an $\infty$-operad, we conclude that $q \circ j$ and $g''_0$ are both $q'$-limit diagrams in $O^\circ$ extending $q \circ g''_0$, and therefore homotopic via a homotopy which is
fixed on $X'$ and compatible with the projection to $N(\text{Fin}_\ast)$. Since $q$ is a categorial fibration, we can lift this equivalence to a homotopy $j \simeq g''$, where $g'' : \tau_b \ast X' \to \mathcal{C}^\otimes$ is the desired extension of $g_0'$. We note that this construction ensures that condition $(ii)$ is satisfied.

\end{proof}

### 3.1.3 Construction of Free Algebras

Let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a fibration of $\infty$-operads, and suppose we are given $\infty$-operad maps $A^\otimes \xleftarrow{i} B^\otimes \xrightarrow{j} \mathcal{O}^\otimes$. Composition with $i$ induces a forgetful functor $\theta : \text{Alg}_{B^\otimes/\mathcal{O}}(\mathcal{C}) \to \text{Alg}_{A^\otimes/\mathcal{O}}(\mathcal{C})$. Our goal in this section is to show that, under suitable conditions, the functor $\theta$ admits a left adjoint. This left adjoint can be described informally as carrying an algebra $F \in \text{Alg}_{A^\otimes/\mathcal{O}}(\mathcal{C})$ to the free $\mathcal{B}$-algebra generated by $F$.

Our first step is to describe the structure of free algebras more explicitly. Suppose we are given an algebra object $F' \in \text{Alg}_{B^\otimes/\mathcal{O}}(\mathcal{C})$ and a map of $A$-algebras $F \to \theta(F')$. What can we say about the object $F'(B) \in \mathcal{C}$, where $B \in \mathcal{B}$ is some object? For every $A \in A^\otimes$ and every active morphism $i(A) \to B$ in $A^\otimes$, we obtain a composite map

$$F(A) \to \theta(F')(A) = F'(i(A)) \to F'(B)$$

in the $\infty$-operad $\mathcal{C}^\otimes$. We will say that $F'$ is freely generated by $F$ if each $F'(B) \in \mathcal{C}$ is universal with respect to the existence of these maps (for each $B \in \mathcal{B}$). More precisely, we have the following definition:

**Definition 3.1.3.1.** Let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ and $A^\otimes \xleftarrow{i} B^\otimes \xrightarrow{j} \mathcal{O}^\otimes$ be as above, let $A \in \text{Alg}_{A^\otimes/\mathcal{O}}(\mathcal{C})$ and $F \in \text{Alg}_{B^\otimes/\mathcal{O}}(\mathcal{C})$, and let $f : F \to \theta(F')$ be a morphism of $A$-algebra objects in $\mathcal{C}$.

For every object $B \in \mathcal{B}$, we let $(A^\otimes_{\text{act}})_{/B}$ denote the fiber product $A^\otimes \times_{\mathcal{B}^\otimes}(\mathcal{B}^\otimes_{\text{act}})/B$. The maps $F$ and $F'$ induce maps $\alpha, \alpha' : (A^\otimes_{\text{act}})_{/B} \to \mathcal{O}^\otimes_{\text{act}}$, $f$ determines a natural transformation $g : \alpha \to \alpha'$. We note that $\alpha'$ lifts to a map $\overline{g} : (A^\otimes_{\text{act}})_{/B} \to (\mathcal{O}^\otimes_{\text{act}})/F'(B)$; since the projection $(\mathcal{O}^\otimes_{\text{act}})/F'(B) \to \mathcal{O}^\otimes_{\text{act}} \times_{\mathcal{O}^\otimes_{\text{act}}} (\mathcal{O}^\otimes_{\text{act}})/F'(B)$ is a right fibration, we can lift $g$ (in an essentially unique fashion) to a natural transformation $\overline{g} : \overline{\alpha} \to \overline{\alpha'}$ which is compatible with the projection to $\mathcal{O}^\otimes$.

We will say that $\overline{g}$ exhibits $F'$ as a $q$-free $\mathcal{B}$-algebra generated by $F$ if the following condition is satisfied, for every object $B \in \mathcal{B}$:

\begin{itemize}
  \item[(*)] The map $\overline{\alpha}$ above determines an operadic $q$-colimit diagram $(A^\otimes_{\text{act}})_{/B} \to \mathcal{C}^\otimes$.
\end{itemize}

The following result guarantees that free algebras have the expected universal property (and are therefore unique up to equivalence, whenever they exist):

**Proposition 3.1.3.2.** Let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a fibration of $\infty$-operads, and suppose we are given maps of $\infty$-operads $A^\otimes \to B^\otimes \to \mathcal{O}^\otimes$. Let $\theta : \text{Alg}_{B^\otimes/\mathcal{O}}(\mathcal{C}) \to \text{Alg}_{A^\otimes/\mathcal{O}}(\mathcal{C})$ denote the forgetful functor, let $F \in \text{Alg}_{A^\otimes/\mathcal{O}}(\mathcal{C})$, let $F' \in \text{Alg}_{B^\otimes/\mathcal{O}}(\mathcal{C})$, and let $f : F \to \theta(F')$ be a map which exhibits $F'$ as a $q$-free $\mathcal{B}$-algebra generated by $F$. For every $F'' \in \text{Alg}_{B^\otimes/\mathcal{O}}(\mathcal{C})$, composition with $f$ induces a homotopy equivalence

$$\gamma : \text{Map}_{\text{Alg}_{B^\otimes/\mathcal{O}}(\mathcal{C})}(F', F'') \to \text{Map}_{\text{Alg}_{A^\otimes/\mathcal{O}}(\mathcal{C})}(F, \theta(F''))).$$

We also have the following general existence result for free algebras:

**Proposition 3.1.3.3.** Let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a fibration of $\infty$-operads, and suppose we are given maps of $\infty$-operads $A^\otimes \to B^\otimes \to \mathcal{O}^\otimes$. Let $\theta : \text{Alg}_{B^\otimes/\mathcal{O}}(\mathcal{C}) \to \text{Alg}_{A^\otimes/\mathcal{O}}(\mathcal{C})$ denote the forgetful functor and let $F \in \text{Alg}_{A^\otimes/\mathcal{O}}(\mathcal{C})$. The following conditions are equivalent:

\begin{enumerate}
  \item There exists $F' \in \text{Alg}_{B^\otimes/\mathcal{O}}(\mathcal{C})$ and a map $F \to \theta(F')$ which exhibits $F'$ as a $q$-free $\mathcal{B}$-algebra generated by $F$.
\end{enumerate}
(2) For every object \(B \in \mathcal{B}\), the induced map
\[
(A_{\text{act}}^\otimes)_{/B} \rightarrow A_{\text{act}}^\otimes \xrightarrow{\theta^\otimes} \mathcal{C}_{\text{act}}^\otimes
\]
can be extended to an operadic \(q\)-colimit diagram lying over the composition
\[
(A_{\text{act}}^\otimes)^\otimes_{/B} \rightarrow \mathcal{B}_{\text{act}}^\otimes \rightarrow \mathcal{O}_{\text{act}}^\otimes.
\]

Let us postpone the proofs of Proposition 3.1.3.2 and 3.1.3.3 for the moment, and study some applications.

**Corollary 3.1.3.4.** Let \(q : \mathcal{C}^\otimes \rightarrow \mathcal{O}^\otimes\) be a fibration of \(\infty\)-operads, and suppose we are given maps of \(\infty\)-operads \(A^\otimes \rightarrow \mathcal{B}^\otimes \rightarrow \mathcal{O}^\otimes\). Assume that the following condition is satisfied:

(*) For every object \(B \in \mathcal{B}\) and every \(F \in \text{Alg}_{\mathcal{A}/\mathcal{O}}(\mathcal{C})\), the diagram
\[
(A_{\text{act}}^\otimes)_{/B} \rightarrow A_{\text{act}}^\otimes \xrightarrow{\theta^\otimes} \mathcal{C}_{\text{act}}^\otimes
\]
can be extended to an operadic \(q\)-colimit diagram lifting the composition
\[
(A_{\text{act}}^\otimes)^\otimes_{/B} \rightarrow (\mathcal{B}_{\text{act}}^\otimes)_{/B} \rightarrow \mathcal{B}_{\text{act}}^\otimes \rightarrow \mathcal{O}_{\text{act}}^\otimes.
\]

Then the forgetful functor \(\theta : \text{Alg}_{\mathcal{B}/\mathcal{O}}(\mathcal{C}) \rightarrow \text{Alg}_{\mathcal{A}/\mathcal{O}}(\mathcal{C})\) admits a left adjoint, which carries each \(F \in \text{Alg}_{\mathcal{A}/\mathcal{O}}(\mathcal{C})\) to a \(q\)-free \(\mathcal{B}\)-algebra generated by \(F\).

*Proof.* Combine Propositions 3.1.3.3, 3.1.3.2, and T.5.2.2.12. \(\square\)

**Corollary 3.1.3.5.** Let \(\kappa\) be an uncountable regular cardinal, let \(\mathcal{O}^\otimes\) be an \(\infty\)-operad, and let \(\mathcal{C}^\otimes \rightarrow \mathcal{O}^\otimes\) be coCartesian fibration of \(\infty\)-operads which is compatible with \(\kappa\)-small colimits (see Variant 3.1.1.19). Suppose we are given maps of \(\infty\)-operads \(A^\otimes \rightarrow \mathcal{B}^\otimes \rightarrow \mathcal{O}^\otimes\), where \(A^\otimes\) and \(\mathcal{B}^\otimes\) are essentially \(\kappa\)-small. Then the forgetful functor \(\text{Alg}_{\mathcal{B}/\mathcal{O}}(\mathcal{C}) \rightarrow \text{Alg}_{\mathcal{A}/\mathcal{O}}(\mathcal{C})\) admits a left adjoint, which carries each \(\mathcal{O}'\)-algebra \(F\) in \(\mathcal{C}\) to a \(q\)-free \(\mathcal{O}\)-algebra generated by \(F\).

*Proof.* Combine Proposition 3.1.1.20 with Corollary 3.1.3.4. \(\square\)

**Example 3.1.3.6.** Let \(\mathcal{O}^\otimes\) be a \(\kappa\)-small \(\infty\)-operad, let \(p : \mathcal{C}^\otimes \rightarrow \mathcal{O}^\otimes\) be a coCartesian fibration of \(\infty\)-operads which is compatible with \(\kappa\)-small colimits. Applying Corollary 3.1.3.5 in the case where \(\mathcal{B}^\otimes = \mathcal{O}^\otimes\) and \(A^\otimes = \mathcal{O}^\otimes \times_{\text{N}(p_{\text{fin}})} \text{Triv}^\otimes\) (and using Example 2.1.3.5), we deduce that the forgetful functor \(\text{Alg}_{/\mathcal{O}}(\mathcal{C}) \rightarrow \text{Fun}_{\mathcal{O}}(\mathcal{O}, \mathcal{C})\) admits a left adjoint.

**Corollary 3.1.3.7.** Let \(q : \mathcal{C}^\otimes \rightarrow \mathcal{O}^\otimes\) be a coCartesian fibration of \(\infty\)-operads and let \(\mathcal{O}_0^\otimes\) denote the \(\infty\)-operad given by the fiber product \(\mathcal{O}^\otimes \times_{\text{Comm}^\otimes} \mathcal{C}^\otimes\) (see Example 2.1.1.19). Assume that \(\mathcal{O}_0^\otimes\) is unital and that there exists an uncountable regular cardinal \(\kappa\) with the following properties:

1. The \(\infty\)-operad \(\mathcal{O}^\otimes\) is essentially \(\kappa\)-small.
2. For each object \(X \in \mathcal{O}\), the \(\infty\)-category \(\mathcal{C}_X\) admits \(K\)-indexed colimits for every weakly contractible \(\kappa\)-small simplicial set \(K\).
3. For every collection of objects \(X_1, \ldots, X_n, Y \in \mathcal{O}\) and every operation \(\alpha \in \text{Mul}_\mathcal{O}(\{X_i\}, Y)\), the associated functor
\[
\prod_{1 \leq i \leq n} \mathcal{C}_{X_i} \rightarrow \mathcal{C}_Y
\]
preserves \(K\)-indexed colimits separately in each variable for every weakly contractible \(\kappa\)-small simplicial set \(K\).
Then the forgetful functor \( \theta : \Alg_\cO(\cC) \to \Alg_{\cO_{fam}}(\cC) \) admits a left adjoint which carries each \( F \in \Alg_{\cO_{fam}}(\cC) \) to a \( q \)-free \( \cO \)-algebra generated by \( F \).

**Proof.** Let \( F \in \Alg_{\cO_{fam}}(\cC) \); we wish to prove the existence of a \( q \)-free \( \cO \)-algebra generated by \( F \). For this, it will suffice to verify condition (\( \ast \)) of Corollary 3.1.3.4. Fix an object \( X \in \cO \); we wish to show that the map

\[
\cO_0^\otimes \times_{\cO^\otimes} (\cO_{\text{act}}^\otimes)_{/X} \to \cO_{\text{act}}^\otimes
\]

can be extended to an operadic \( q \)-colimit diagram lifting the composition

\[
(\cO_0^\otimes \times_{\cO^\otimes} (\cO_{\text{act}}^\otimes)_{/X})^\circ \to (\cO_{\text{act}}^\otimes)_{/X} \to \cO_{\text{act}}^\otimes.
\]

Assumption (1) implies that the \( \infty \)-category \( \cO_0^\otimes \times_{\cO^\otimes} (\cO_{\text{act}}^\otimes)_{/X} \) is essentially \( \kappa \)-small, and the assumption that \( \cO^\otimes \) is unital guarantees that it is weakly contractible (in fact, it has an initial object). Using assumption (3) together with Propositions 3.1.1.15 and 3.1.1.16, we are reduced to proving the existence of the colimit of a diagram

\[
\cO_0^\otimes \times_{\cO^\otimes} (\cO_{\text{act}}^\otimes)_{/X} \to \cE_X,
\]

which follows from assumption (2). \( \square \)

**Remark 3.1.3.8.** In the situation of Corollary 3.1.3.7, suppose we are given a \( \cO \)-monoidal functor \( T : \cC^\otimes \to \cD^\otimes \), where \( r : \cD^\otimes \to \cO^\otimes \) is a coCartesian fibration of \( \infty \)-operads which also satisfies hypotheses (2) and (3). Suppose further that for each object \( X \in \cO \), the induced map \( \cE_X \to \cD_X \) preserves colimits indexed by \( \kappa \)-small weakly contractible simplicial sets. If we are given algebra objects \( A \in \Alg_{\cO_{fam}}(\cC) \) and \( B \in \Alg_{\cO}(\cC) \) and a morphism \( A \to B_{\cO_0^\otimes} \) which exhibits \( B \) as a \( q \)-free \( \cO \)-algebra generated by \( A \), then the induced map \( T(A) \to T(B)|_{\cO_0^\otimes} \) exhibits \( T(B) \) as the \( r \)-free \( \cO \)-algebra generated by \( T(A) \in \Alg_{\cO_{fam}}(\cC) \). This follows immediately from the proof of Corollary 3.1.3.7.

To apply Corollary 3.1.3.5 in practice, it it convenient to have a more explicit description of free algebras. To obtain such a description, we will specialize to the case where the \( \infty \)-operad \( \cA^\otimes \) is trivial.

**Construction 3.1.3.9.** Let \( \cO^\otimes \) be an \( \infty \)-operad, let \( X, Y \in \cO \) be objects, and let \( f : \Triv^\otimes \to \cO^\otimes \) be a map of \( \infty \)-operads such that \( f(1) = X \) (such a map exists and is unique up to equivalence, by Remark 2.1.3.6).

Let \( p : \cC^\otimes \to \cO^\otimes \) be a coCartesian fibration of \( \infty \)-operads and let \( C \in \cE_X \) be an object. Using Example 2.1.3.5, we conclude that \( C \) determines an essentially unique \( \cO \)-algebra \( \cC \in \Alg_{\cO}(\cC) \) such that \( \cC(1) = C \).

For each \( n \geq 0 \), let \( \mathcal{P}(n) \) denote the full subcategory of \( \Triv^\otimes \times_{\cO^\otimes} \cO^\otimes \) spanned by the active morphisms \( f(n) \to Y \); we observe that \( \mathcal{P}(n) \) is a Kan complex and that the fibers of the canonical map \( q : \mathcal{P}(n) \to N(\Sigma_n) \) can be identified with the space of \( n \)-ary operations \( \text{Mul}_{\cO}(\{X\}_{1 \leq i \leq n}, Y) \). By construction, we have a canonical map \( h : \mathcal{P}(n) \times \Delta^1 \to \cO^\otimes \) which we regard as a natural transformation from \( h_0 = f \circ q \) to the constant map \( h_1 : \mathcal{P}(n) \to \{Y\} \). Since \( p \) is a coCartesian fibration, we can choose a \( p \)-coCartesian natural transformation \( \overline{h} : \cC \circ q \to \overline{h}_1 \), for some map \( \overline{h}_1 : \mathcal{P}(n) \to \cE_Y \). We let \( \text{Sym}^n_{\cO,Y}(C) \) denote a colimit of the diagram \( \overline{h}_1 \), if such a colimit exists. We observe that \( \text{Sym}^n_{\cO,Y}(C) \in \cE_Y \) is well-defined up to equivalence (in fact, up to a contractible space of choices).

**Notation 3.1.3.10.** In the special case \( X = Y \), we will simply write \( \text{Sym}^n_{\cO}(C) \) for \( \text{Sym}^n_{\cO,Y}(C) \). When \( \cO^\otimes \) is the commutative \( \infty \)-operad \( N(\text{Fin}_*) \) (so that \( X = Y = (1) \)) we will denote \( \text{Sym}^n_{\cO}(C) \) by \( \text{Sym}^n(C) \).

**Remark 3.1.3.11.** In the situation of Construction 3.1.3.9, suppose that \( A \in \Alg_{\cO}(\cC) \) is a \( \cO \)-algebra and that we are equipped with a map \( \overline{h} \to A \circ f \) of \( \cO \)-algebras (in view of Example 2.1.3.5, this is equivalent to giving a map \( C \to A(X) \) in \( \cE_X \)). This map induces a natural transformation from \( \overline{h}_1 \) to the constant map \( \mathcal{P}(n) \to \{A(Y)\} \subseteq \cC \), which we can identify with a map \( \text{Sym}^n_{\cO,Y}(C) \to A(Y) \) (provided that the left side is well-defined).
Definition 3.1.3.12. Let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a coCartesian fibration of $\infty$-operads, let $X \in \mathcal{O}$, let $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$, and suppose we are given a morphism $f : C \to A(X)$ in $\mathcal{C}_X$. Using Remark 2.1.3.6 and Example 2.1.3.5, we can extend (in an essentially unique way) $X$ to an $\infty$-operad map $\text{Triv} \to \mathcal{O}$, $C$ to an object $\overline{C} \in \text{Alg}_{\text{Triv} / \mathcal{O}}(\mathcal{C})$, and $f$ to a map of $\text{Triv}$-algebras $\overline{f} : \overline{C} \to \text{Triv}$. We will say that $\overline{f}$ exhibits $A$ as a free $\mathcal{O}$-algebra generated by $\overline{C}$ if $\overline{f}$ exhibits $A$ as a $q$-free $\mathcal{O}$-algebra generated by $\overline{C}$.

Proposition 3.1.3.13. Let $\kappa$ be an uncountable regular cardinal, $\mathcal{O}^\otimes$ a $\kappa$-small $\infty$-operad, and $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ a coCartesian fibration of $\infty$-operads which is compatible with $\kappa$-small colimits. Let $X \in \mathcal{O}$ and let $C \in \mathcal{C}_X$. Then:

(i) There exists an algebra $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ and a map $C \to A(X)$ which exhibits $A$ as a free $\mathcal{O}$-algebra generated by $X$.

(ii) An arbitrary map $f : C \to A(X)$ as in (i) exhibits $A$ as a free $\mathcal{O}$-algebra generated by $X$ if and only if, for every object $Y \in \mathcal{O}$, the maps $\text{Sym}_{\mathcal{O},Y}^\kappa(C) \to A(Y)$ of Remark 3.1.3.11 exhibit $A(Y)$ as a coproduct $\coprod_{n \geq 0} \text{Sym}_{\mathcal{O},Y}^n(C)$.

Proof. Assertion (i) is a special case of Corollary 3.1.3.5. Assertion (ii) follows by combining the criterion of Corollary 3.1.3.5 with Propositions 3.1.1.15 and 3.1.1.16. \hfill \Box

Example 3.1.3.14. Let $\mathcal{C}^\otimes$ be a symmetric monoidal $\infty$-category. Assume that the underlying $\infty$-category $\mathcal{C}$ admits countable colimits, and that for each $X \in \mathcal{C}$ the functor $Y \mapsto X \otimes Y$ preserves countable colimits. Then the forgetful functor $\text{CAlg}(\mathcal{C}) \to \mathcal{C}$ admits a left adjoint, which is given informally by the formula

$$C \mapsto \coprod_{n \geq 0} \text{Sym}^n(C).$$

The following observation allows us to reformulate Propositions 3.1.3.2 and 3.1.3.3 in terms of the theory of operadic left Kan extensions developed in §3.1.2:

Remark 3.1.3.15. Let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$, $A^\otimes \xrightarrow{\theta} \mathcal{B}^\otimes \to \mathcal{O}^\otimes$, $\theta : \text{Alg}_{\mathcal{B} / \mathcal{O}}(\mathcal{C}) \to \text{Alg}_{A / \mathcal{O}}(\mathcal{C})$, and $f : F \to \theta(F')$ be as in Definition 3.1.3.1. The maps $f$, $F$, and $F'$ determine a map

$$h : (A^\otimes \times \Delta^1) \coprod_{A^\otimes \times \{1\}} \mathcal{B}^\otimes \to \mathcal{C}^\otimes \times \Delta^1.$$ 

Choose a factorization of $h$ as a composition

$$(A^\otimes \times \Delta^1) \coprod_{A^\otimes \times \{1\}} \mathcal{B}^\otimes \xrightarrow{h'} \mathcal{M}^\otimes \xrightarrow{h''} \mathcal{C}^\otimes \times \Delta^1$$

where $h'$ is a categorical equivalence and $\mathcal{M}^\otimes$ is an $\infty$-category; we note that the composite map $\mathcal{M}^\otimes \to \text{N}(\text{Fin}_n) \times \Delta^1$ is a correspondence of $\infty$-operads. Unwinding the definitions, we see that $f$ exhibits $F'$ as a $q$-free $\mathcal{B}$-algebra generated by $F$ if and only if the map $h''$ is an operadic $q$-left Kan extension.

We will also need the following general observation concerning operadic left Kan extensions:

Lemma 3.1.3.16. Let $\mathcal{M}^\otimes \to \text{N}(\text{Fin}_n) \times \Delta^1$ be a correspondence between $\infty$-operads $A^\otimes$ and $\mathcal{B}^\otimes$, and let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a fibration of $\infty$-operads. Suppose that $n > 0$ and we are given a diagram

$$
\begin{array}{ccc}
(A^\otimes \times \Delta^n) \coprod_{A^\otimes \times \partial \Delta^n} (\mathcal{M}^\otimes \times \partial \Delta^n) & \xrightarrow{f_0} & \mathcal{O}^\otimes \\
\downarrow & & \downarrow \\
\mathcal{M}^\otimes \times \Delta^n & \xrightarrow{f} & \mathcal{O}^\otimes
\end{array}
$$

where the dotted arrow $f_0$ is the $q$-free $\mathcal{O}$-algebra generated by $f$. Then $f_0$ exhibits $A$ as a free $\mathcal{O}$-algebra generated by $\mathcal{M}$.
where \( f \) is a map of generalized \( \infty \)-operads, the restriction of \( f_0 \) to \( A^\otimes \times \Delta^n \) is a map of generalized \( \infty \)-operads, the restriction of \( f_0 \) to \( M^\otimes \times \sigma \) is a map of generalized \( \infty \)-operads for every simplex \( \sigma \subseteq \partial \Delta^n \), and the restriction of \( f_0 \) to \( M^\otimes \times \{0\} \) is an operadic \( q \)-left Kan extension. Then there exists a functor \( f \) as indicated in the diagram, which is a map of generalized \( \infty \)-operads.

**Proof.** Let \( K(0) = (\Delta^n \times \{0\}) \coprod_{\Delta^n \times \{0\}} (\partial \Delta^n \times \Delta^1) \), which we identify with a simplicial subset of \( \Delta^n \times \Delta^1 \). We define a sequence of simplicial subsets

\[
K(0) \subseteq K(1) \subseteq \ldots \subseteq K(n + 1) = \Delta^n \times \Delta^1
\]

so that each \( K(i + 1) \) is obtained from \( K(i) \) by adjoining the image of the simplex \( \sigma_i : \Delta^{n+1} \to \Delta^n \times \Delta^1 \) which is given on vertices by the formula

\[
\sigma_i(j) = \begin{cases} 
(j, 0) & \text{if } j \leq n - i \\
(j - 1, 1) & \text{otherwise.}
\end{cases}
\]

We construct a compatible family of maps \( f_i : K(i) \times \Delta^1 \to M^\otimes \to \mathcal{O}^\otimes \) extending \( f_0 \) using induction on \( i \). Assuming \( f_i \) has been constructed, to build \( f_{i+1} \) it suffices to solve the lifting problem presented in the following diagram:

\[
\begin{array}{ccc}
\Lambda^{n+1}_{n-i} \times \Delta^1 \to M^\otimes & \overset{j}{\to} & \mathcal{O}^\otimes \\
\downarrow & & \downarrow \\
\Delta^{n+1} \times \Delta^1 & \to & \mathcal{O}^\otimes
\end{array}
\]

If \( i < n \), then Lemma 2.4.4.6 guarantees that \( j \) is a categorical equivalence, so the dotted arrow exists by virtue of the fact that \( q \) is a categorical fibration. If \( i = n \), then the lifting problem admits a solution by Theorem 3.1.2.3. \( \square \)

**Notation 3.1.3.17.** Let \( q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads, let \( M^\otimes \to N(\text{Fin}_n) \times \Delta^1 \) be a correspondence between \( \infty \)-operads, and suppose we are given a map of generalized \( \infty \)-operads \( M^\otimes \to \mathcal{O}^\otimes \). We let \( \text{Alg}_{M^\otimes / \mathcal{O}}(\mathcal{C}) \) denote the full subcategory of \( \text{Fun}_{\mathcal{O}^\otimes}(M^\otimes, \mathcal{C}^\otimes) \) spanned by the maps of generalized \( \infty \)-operads.

We are now ready to give the proofs of Proposition 3.1.3.2 and 3.1.3.3.

**Proof of Proposition 3.1.3.2.** The triple \((F, F'', f)\) determines a map \( h : (A^\otimes \times \Delta^1) \coprod_{A^\otimes \times \{1\}} (B^\otimes \times \{1\}) \to \mathcal{C}^\otimes \times \Delta^1 \). Choose a factorization of \( h \) as a composition

\[
(A^\otimes \times \Delta^1) \coprod_{A^\otimes \times \{1\}} (B^\otimes \times \{1\}) \overset{h'}{\to} M^\otimes \overset{h''}{\to} \mathcal{C}^\otimes \times \Delta^1
\]

where \( h' \) is a categorical equivalence and \( M^\otimes \) is a correspondence of \( \infty \)-operads from \( A^\otimes \) to \( B^\otimes \). Let \( \text{Alg}_{M^\otimes / \mathcal{O}}(\mathcal{C}) \) denote the full subcategory of \( \text{Alg}_{M^\otimes / \mathcal{O}}(\mathcal{C}) \) spanned by the functors \( M^\otimes \to \mathcal{C}^\otimes \) which are operadic \( q \)-left Kan extensions, and let \( \text{Alg}_{M^\otimes / \mathcal{O}}(\mathcal{C}) \) denote the full subcategory of \( \text{Alg}_{M^\otimes / \mathcal{O}}(\mathcal{C}) \) spanned by those functors which are \( q \)-right Kan extensions of their restrictions to \( B^\otimes \). Proposition T.4.3.2.15 guarantees that the restriction map \( \text{Alg}_{M^\otimes / \mathcal{O}}(\mathcal{C}) \to \text{Alg}_{B^\otimes / \mathcal{O}}(\mathcal{C}) \) is a trivial Kan fibration; let \( s : \text{Alg}_{B^\otimes / \mathcal{O}}(\mathcal{C}) \to \text{Alg}_{M^\otimes / \mathcal{O}}(\mathcal{C}) \) be a section. We observe that the functor \( \delta \) is equivalent to the composition of \( s \) with the restriction map \( \text{Alg}_{M^\otimes / \mathcal{O}}(\mathcal{C}) \to \text{Alg}_{A^\otimes / \mathcal{O}}(\mathcal{C}) \). Let \( \mathcal{F} \in \text{Alg}_{M^\otimes / \mathcal{O}}(\mathcal{C}) \) be the object determined by \( h'' \) so that we have a homotopy commutative diagram

\[
\begin{array}{ccc}
\text{Map}_{\text{Alg}_{M^\otimes / \mathcal{O}}(\mathcal{C})}(\mathcal{F}, s(F'')) & \xrightarrow{\beta} & \text{Map}_{\text{Alg}_{A^\otimes / \mathcal{O}}(\mathcal{C})}(F, s(F'')) \\
\text{Map}_{\text{Alg}_{B^\otimes / \mathcal{O}}(\mathcal{C})}(F', F'') & \xrightarrow{\beta'} & \text{Map}_{\text{Alg}_{A^\otimes / \mathcal{O}}(\mathcal{C})}(F, s(F''))
\end{array}
\]
where $\gamma$ can be identified with the bottom horizontal map. By the two-out-of-three property, it will suffice to show that $\beta$ and $\beta'$ are trivial Kan fibrations. For the map $\beta$, this follows from the observation that $s(F'')$ is a $q$-right Kan extension of $F''$. For the map $\beta'$, we apply Lemma 3.1.3.16 (together with the observation that $F$ is an operadic $q$-left Kan extension, by virtue of Remark 3.1.3.15).

Proof of Proposition 3.1.3.3. The implication (1) $\Rightarrow$ (2) is obvious. For the converse, we use the small object argument to choose a factorization of the map $h : (A^\otimes \times \Delta^1) \coprod_{A^\otimes \times \{1\}} B^\otimes \to O^\otimes \times \Delta^1$ as a composition

\[(A^\otimes \times \Delta^1) \coprod_{A^\otimes \times \{1\}} B^\otimes \xrightarrow{h'} M^\otimes \xrightarrow{h''} O^\otimes \times \Delta^1\]

where $h'$ is inner anodyne and $M^\otimes$ is a correspondence of $\infty$-operads from $A^\otimes$ to $B^\otimes$. Using assumption (2) and Theorem 3.1.2.3, we can solve the lifting problem depicted in the diagram

\[
\begin{array}{ccc}
A^\otimes & \longrightarrow & C^\otimes \\
\downarrow & & \downarrow \\
M^\otimes & \longrightarrow & O^\otimes \\
\end{array}
\]

in such a way that $G$ is an operadic $q$-left Kan extension. Composing $G$ with $h'$, we obtain an object $F' \in \text{Alg}_{B/O}(C)$ and a natural transformation $f : F \to \theta(F')$. It follows from Remark 3.1.3.15 that $f$ exhibits $F'$ as a $q$-free $B$-algebra generated by $F$.

\[\square\]

### 3.1.4 Transitivity of Operadic Left Kan Extensions

Our goal in this section is to prove the following transitivity formula for operadic left Kan extensions:

**Theorem 3.1.4.1.** Let $M^\otimes \to \Delta^2 \times N(\text{Fin}_*)$ be a $\Delta^2$-family of $\infty$-operads (Definition 2.3.2.10). Let $q : C^\otimes \to D^\otimes$ be a fibration of $\infty$-operads, and let $A : M^\otimes \to C^\otimes$ be a map of generalized $\infty$-operads. Assume that $A|(M^\otimes \times \Delta^2 \Delta^{0,1})$ and $A|(M^\otimes \times \Delta^2 \Delta^{1,2})$ are operadic $q$-left Kan extensions, and that the map $M^\otimes \to \Delta^2$ is a flat categorical fibration (see Definition B.3.8). Then $A|(M^\otimes \times \Delta^2 \Delta^{0,2})$ is an operadic $q$-left Kan extension.

Theorem 3.1.4.1 has the following consequence:

**Corollary 3.1.4.2.** Let $M^\otimes \to \Delta^2 \times N(\text{Fin}_*)$ be a $\Delta^2$-family of $\infty$-operads, $q : C^\otimes \to N(\text{Fin}_*)$ a symmetric monoidal $\infty$-category, and $\kappa$ an uncountable regular cardinal. Assume that:

(i) The $\infty$-category $M^\otimes$ is essentially $\kappa$-small.

(ii) The $\infty$-category $C$ admits $\kappa$-small colimits, and the tensor product on $C$ preserves $\kappa$-small colimits separately in each variable.

(iii) The projection map $M^\otimes \to \Delta^2$ is a flat categorical fibration.

For $i \in \{0, 1, 2\}$, let $M^\otimes_i$ denote the fiber $M^\otimes \times \Delta^2 \{i\}$. Let $f_{0,1} : \text{Alg}_{M^\otimes_0}(C) \to \text{Alg}_{M^\otimes_1}(C)$, $f_{1,2} : \text{Alg}_{M^\otimes_1}(C) \to \text{Alg}_{M^\otimes_2}(C)$, and $f_{0,2} : \text{Alg}_{M^\otimes_0}(C) \to \text{Alg}_{M^\otimes_2}(C)$ be the functors given by operadic $q$-left Kan extension (see below). Then there is a canonical equivalence of functors $f_{0,2} \simeq f_{1,2} \circ f_{0,1}$.

**Proof.** For $0 \leq i \leq j \leq 2$, let $\text{Alg}_{i,j}(C)$ denote the full subcategory of $\text{Fun}_{N(\text{Fin}_*)}(M^\otimes \times \Delta^2 \Delta^{i,j}, C^\otimes)$ spanned by those $\infty$-operad family maps which are operadic $q$-left Kan extensions, where $q : C^\otimes \to N(\text{Fin}_*)$ denotes the projection. Using Lemma 3.1.3.16, Theorem 3.1.2.3, and Proposition 3.1.1.20, we see that conditions (i) and (ii) guarantee that the restriction map $r : \text{Alg}_{i,j}(C) \to \text{Alg}_{M^\otimes_i}(C)$ is a trivial Kan fibration. The map $f_{i,j}$ is defined to be the composition

\[\text{Alg}_{M^\otimes_j}(C) \xrightarrow{\kappa} \text{Alg}_{i,j}(C) \to \text{Alg}_{M^\otimes_i}(C)\]
where $s$ is a section of $r$. Consequently, the composition $f_{1,2} \circ f_{0,1}$ can be defined as a composition

$$\text{Alg}_{M_0}(\mathcal{C}) \xrightarrow{s'} \text{Alg}_{0,1}(\mathcal{C}) \times_{\text{Alg}_{M_1}(\mathcal{C})} \text{Alg}_{1,2}(\mathcal{C}) \rightarrow \text{Alg}_{M_2}(\mathcal{C}),$$

where $s'$ is a section of the trivial Kan fibration $\text{Alg}_{0,1}(\mathcal{C}) \times_{\text{Alg}_{M_1}(\mathcal{C})} \text{Alg}_{1,2}(\mathcal{C}) \rightarrow \text{Alg}_{M_2}(\mathcal{C})$.

Let $\text{Alg}_{0,1,2}(\mathcal{C})$ denote the full subcategory of $\text{Fun}_{N(\text{Fin})}(\mathcal{M}^\otimes, \mathcal{C}^\otimes)$ spanned by the $\infty$-operad family maps whose restrictions to $\mathcal{M}^\otimes \times_{\Delta^2} \Delta^1(0,1)$ and $\mathcal{M}^\otimes \times_{\Delta^2} \Delta^1(1,2)$ are operadic $q$-left Kan extensions. Condition $(iii)$ guarantees that the inclusion $\mathcal{M}^\otimes \times_{\Delta^2} \Delta^1 \subseteq \mathcal{M}^\otimes$ is a categorical equivalence, so that the restriction maps

$$\text{Fun}_{N(\text{Fin})}(\mathcal{M}^\otimes, \mathcal{C}^\otimes) \rightarrow \text{Fun}_{N(\text{Fin})}(\mathcal{M}^\otimes \times_{\Delta^2} \Delta^1, \mathcal{C}^\otimes)$$

$$\text{Alg}_{0,1,2}(\mathcal{C}) \rightarrow \text{Alg}_{0,1}(\mathcal{C}) \times_{\text{Alg}_{M_1}(\mathcal{C})} \text{Alg}_{1,2}(\mathcal{C})$$

are trivial Kan fibrations. It follows that the restriction map $r'' : \text{Alg}_{0,1,2}(\mathcal{C}) \rightarrow \text{Alg}_{M_0}(\mathcal{C})$ is a trivial Kan fibration admitting a section $s''$, and that $f_{1,2} \circ f_{0,1}$ can be identified with the composition

$$\text{Alg}_{M_0}(\mathcal{C}) \xrightarrow{s''} \text{Alg}_{0,1,2}(\mathcal{C}) \rightarrow \text{Alg}_{M_2}(\mathcal{C}).$$

Using Theorem 3.1.4.1, we deduce that the restriction map $\text{Alg}_{0,1,2}(\mathcal{C}) \rightarrow \text{Alg}_{M_2}(\mathcal{C})$ factors as a composition

$$\text{Alg}_{0,1,2}(\mathcal{C}) \xrightarrow{\theta} \text{Alg}_{0,2}(\mathcal{C}) \xrightarrow{\theta'} \text{Alg}_{M_2}(\mathcal{C}).$$

The composition $\theta \circ s''$ is a section of the trivial Kan fibration $\text{Alg}_{0,2}(\mathcal{C}) \rightarrow \text{Alg}_{M_0}(\mathcal{C})$, so that $f_{0,2}$ can be identified with the composition $\theta' \circ (\theta \circ s'') \simeq f_{1,2} \circ f_{0,1}$ as desired.

The proof of Theorem 3.1.4.1 rests on a more basic transitivity property of operadic colimit diagrams. To state this property, we need to introduce a bit of terminology. Let $q : \mathcal{C}^\otimes \rightarrow \mathcal{D}^\otimes$ be a fibration of $\infty$-operads, and let $p : K \circ \Delta^0 \rightarrow \mathcal{C}^\otimes$ be a map of simplicial sets which carries each edge of $K \circ \Delta^0$ to an active morphism in $\mathcal{C}^\otimes$. Since the map $K \circ \Delta^0 \rightarrow K^\otimes$ is a categorical equivalence (Proposition T.4.2.1.2), there exists a map $p' : K^\otimes \rightarrow \mathcal{C}^\otimes$ such that $p$ is homotopic to the composition $K \circ \Delta^0 \rightarrow K^\otimes \xrightarrow{p'} \mathcal{C}^\otimes$. Moreover, the map $p'$ is unique up to homotopy. We will say that $p$ is a (weak) operadic $q$-colimit diagram if $p'$ is a (weak) operadic $q$-colimit diagram, in the sense of Definition 3.1.1.2.

**Lemma 3.1.4.3.** Let $X \rightarrow S$ be a coCartesian fibration of simplicial sets, and let $q : \mathcal{C}^\otimes \rightarrow \mathcal{D}^\otimes$ be a fibration of $\infty$-operads. Let

$$\theta : (X \circ_S S) = (X \times \Delta^1) \coprod_{X \times \{1\}} S \rightarrow \mathcal{C}^\otimes$$

be a map satisfying the following conditions:

(i) The map $\theta$ carries every edge in $X \circ_S S$ to an active morphism in $\mathcal{C}^\otimes$.

(ii) For every vertex $s \in S$, the induced map $\theta_s : X_s \circ \Delta^0 \rightarrow \mathcal{C}^\otimes$ is a weak operadic $q$-colimit diagram.

Let $\theta_0 = \theta|X$. Let $\mathcal{C}^\otimes_{\theta_0/}$ denote the full subcategory of $\mathcal{C}^\otimes_{\theta_0/} \times_{\mathcal{C}^\otimes} \mathcal{C}$ spanned by those objects which correspond to maps $\mathcal{B} : (X \circ_S S)^p \rightarrow \mathcal{C}^\otimes$ which carry every edge of $(X \circ_S S)^p$ to an inert morphism of $\mathcal{C}^\otimes$, and define $\mathcal{C}^\otimes_{\theta_0/}^{\text{act}}$, $\mathcal{D}^\otimes_{\theta_0/}^{\text{act}}$ and $\mathcal{D}^\otimes_{\theta_0/}^{\text{act}}$ similarly. Then:

(1) The map $\mathcal{C}^\otimes_{\theta_0/} \rightarrow \mathcal{C}^\otimes_{\theta_0/}^{\text{act}} \times_{\mathcal{D}^\otimes_{\theta_0/}} \mathcal{D}^\otimes_{\theta_0/}^{\text{act}}$ is a trivial Kan fibration.

(2) Let $\mathcal{B} : (X \circ_S S)^p \rightarrow \mathcal{C}^\otimes$ be an extension of $\theta$ which carries each edge of $(X \circ_S S)^p$ to an active morphism in $\mathcal{C}^\otimes$. Then $\mathcal{B}$ is a weak operadic $q$-colimit diagram if and only if $\mathcal{B}_0 = \mathcal{B}|X^p$ is a weak operadic $q$-colimit diagram.
3.1. FREE ALGEBRAS

(3) Assume that each \( \theta_s \) is an operadic \( q \)-colimit diagram, and let \( \overline{\theta} \) be as in (2). Then \( \overline{\theta} \) is an operadic \( q \)-colimit diagram if and only if \( \overline{\theta}_0 \) is an operadic \( q \)-colimit diagram.

Proof. Assertion (2) follows immediately from (1), and assertion (3) follows from (2) after replacing \( \theta \) by the composite functor

\[
X \circ_S S \xrightarrow{\theta} \mathcal{C}^\otimes \bowtie Y \to \mathcal{C}^\otimes,
\]

where \( Y \) denotes an arbitrary object of \( \mathcal{C}^\otimes \). It will therefore suffice to prove (1). For every map of simplicial sets \( K \to S \), let \( \theta_K \) denote the induced map \( X \circ_S K \to \mathcal{C}^\otimes \). We will prove more generally that for \( K' \subseteq K \), the induced map

\[
\psi_{K',K} : \mathcal{C}^\otimes_{\theta_K/} \to \mathcal{C}^\otimes_{\theta_{K'}/} \times_{\mathcal{D}^\otimes_{\psi_{K'/K}} \mathcal{D}^\otimes_{\theta_{K'/K}}}
\]

is a trivial Kan fibration. We proceed by induction on the (possibly infinite) dimension \( n \) of \( K \). If \( K \) is empty, the result is obvious. Otherwise, working simplex-by-simplex, we can assume that \( K \) is obtained from \( K' \) by adjoining a single nondegenerate \( m \)-simplex \( \sigma \) whose boundary already belongs to \( K' \). Replacing \( K \) by \( \sigma \), we may assume that \( K = \Delta^m \) and \( K' = \partial \Delta^m \). If \( m = 0 \), then the desired result follows from assumption (ii). Assume therefore that \( m > 0 \).

Because \( \theta_{K',K} \) is clearly a categorical fibration (even a left fibration), to prove that \( \theta_{K',K} \) is a trivial Kan fibration it suffices to show that \( \theta_{K',K} \) is a categorical equivalence. Since \( m \leq n \), \( K' \) has dimension \( < n \), so the inductive hypothesis guarantees that \( \psi_{\{m\},K'} \) is a trivial Kan fibration. The map \( \psi_{\{m\},K} \) is a composition of \( \psi_{K',K} \) with a pullback of \( \psi_{\{m\},K'} \). Using a two-out-of-three argument, we are reduced to proving that \( \psi_{\{m\},K} \) is a categorical equivalence. For this, it suffices to show that the inclusion \( f : X \circ_S \{m\} \to X \circ_S \Delta^m \) is left cofinal.

Let \( X' = X \times_S \Delta^m \). The map \( f \) is a pushout of the inclusion

\[
f' : X' \coprod_{X_m} (X_m \circ \{m\}) \hookrightarrow X' \circ_{\Delta^m} \Delta^m.
\]

It will therefore suffice to show that \( f' \) is left cofinal. We have a commutative diagram

\[
\begin{array}{ccc}
\{m\} & \xrightarrow{f''} & \Delta^m \\
\downarrow g & & \downarrow g'' \\
X_m \circ \{m\} & \xrightarrow{g'} & X' \coprod_{X_m} (X_m \circ \{m\}) \\
\downarrow f' & & \downarrow X' \circ_{\Delta^m} \Delta^m
\end{array}
\]

The map \( g'' \) is a pushout of the inclusion \( X' \times \{1\} \subseteq X' \times \Delta^1 \), and therefore left cofinal; the same argument shows that \( g \) is left cofinal. The map \( f'' \) is obviously left cofinal. The map \( g' \) is a pushout of the inclusion \( X_m' \subseteq X' \), which is left cofinal because \( \{m\} \) is a final object of \( \Delta^m \) and the map \( X' \to \Delta^m \) is a coCartesian fibration. It now follows from Proposition T.4.1.1.3 that \( f' \) is left cofinal, as required. \( \square \)

Proof of Theorem 3.1.4.1. Fix an object \( Z \in \mathcal{M}_2^\otimes \), and let \( \mathcal{Z} \) denote the full subcategory of \( \mathcal{M}_2^\otimes \) whose objects are active morphisms \( X \to Z \) where \( X \in \mathcal{M}_0^\otimes \). We wish to prove that the composite map

\[
\phi : \mathcal{Z}^\otimes \to (\mathcal{M}_2^\otimes)^\circ \to \mathcal{M}^\otimes \xrightarrow{A} \mathcal{C}^\otimes
\]

is an operadic \( q \)-colimit diagram. Let \( \overline{\mathcal{Z}} \) denote the subcategory of \( \text{Fun}(\Delta^1, \mathcal{M}_2^\otimes) \) whose objects are diagrams of active morphisms

\[
\begin{array}{ccc}
Y & \xrightarrow{Z} & Z \\
\downarrow X & & \downarrow \quad \\
X & \xrightarrow{\phi} & Z
\end{array}
\]
in \( \mathcal{M}^\circ \) such that \( X \in \mathcal{M}_0^\circ \) and \( Y \in \mathcal{M}_1^\circ \). Evaluation at \( \{0\} \) induces a Cartesian fibration \( \psi : \mathcal{Z} \to \mathcal{Z} \). Let \( Z' \) be an object of \( \mathcal{Z} \), corresponding to an active morphism \( X \to Z \) in \( \mathcal{M}^\circ \). Then the fiber \( \psi^{-1}\{Z'\} \) is a localization of the \( \infty \)-category \( (\mathcal{M}^\circ)_{X/\mathcal{Z}} \), which is equivalent to \( (\mathcal{M}^\circ)_{X/\mathcal{Z}} \) and therefore weakly contractible (since \( \mathcal{M}^\circ \to \Delta^2 \) is flat). Note that the map \( \psi' : \mathcal{Z} \times_Z \mathcal{Z}_{Z'/\mathcal{Z}} \to \mathcal{Z}_{Z'/\mathcal{Z}} \) is a Cartesian fibration (Proposition T.2.4.3.2). Since \( \mathcal{Z}_{Z'/\mathcal{Z}} \) has an initial object \( \text{id}_{Z'} \), the weakly contractible simplicial set \( \psi^{-1}\{Z'\} \simeq \psi'^{-1}\{\text{id}_{Z'}\} \) is weakly homotopy equivalent to \( \mathcal{Z} \times_Z \mathcal{Z}_{Z'/\mathcal{Z}} \). Applying Theorem T.4.1.3.1, we deduce that \( \psi \) is left cofinal. Consequently, it will suffice to show that \( \phi \circ \psi : \mathcal{Z} \to \mathcal{C}^\circ \) is an operadic \( q \)-colimit diagram.

Let \( \mathcal{Y} \) denote the full subcategory of \( \mathcal{M}_{/\mathcal{Z}}^\circ \) spanned by active morphisms \( Y \to Z \) where \( Y \in \mathcal{M}_0^\circ \). Evaluation at \( \{1\} \) induces a coCartesian fibration \( \rho : \mathcal{Z} \to \mathcal{Y} \). We observe that there is a canonical map \( \mathcal{Z}_{\circ_Y} \mathcal{Y} \to \mathcal{M}_{/\mathcal{Z}}^\circ \), which determines a map

\[
\theta : (\mathcal{Z}_{\circ_Y} \mathcal{Y})^p \to \mathcal{C}^\circ
\]

extending \( \phi \circ \psi \). Fix an object \( Y' \in \mathcal{Y} \), corresponding to an active morphism \( Y \to Z \) in \( \mathcal{M}^\circ \). Then \( \theta \) induces a map \( \theta_{Y'} : \rho^{-1}\{Y'\} \to \mathcal{C}^\circ \). We claim that \( \theta_{Y'} \) is an operadic \( q \)-colimit diagram. To prove this, let \( \mathcal{X}(Y) \) denote the full subcategory of \( (\mathcal{M}^\circ)_{/\mathcal{Y}} \) spanned by the active morphisms \( X \to Y \), and define \( \mathcal{X}'(Y) \subseteq (\mathcal{M}^\circ)_{/\mathcal{Y}} \) similarly. The map \( \theta_{Y'} \) factors through a map

\[
\theta_{Y'} : \mathcal{X}'(Y) \to \mathcal{C}^\circ.
\]

Since \( \mathcal{M}_{/\mathcal{Z}}^\circ \to \mathcal{M}^\circ \) is a left fibration, the map \( \rho^{-1}\{Y'\} \to \mathcal{X}(Y) \) is a trivial Kan fibration; it therefore suffices to show that \( \theta_{Y'} \) is an operadic \( q \)-colimit diagram. Since the evident map \( \mathcal{X}'(Y) \to \mathcal{X}(Y) \) is a categorical equivalence (Proposition T.4.2.1.5), it suffices to show that the induced map \( \mathcal{X}'(Y) \to \mathcal{C}^\circ \) is an operadic \( q \)-colimit diagram, which is equivalent to the requirement that the composite map

\[
\mathcal{X}'(Y)^p \to (\mathcal{M}^\circ)_{/\mathcal{Y}}^p \to \mathcal{M}^\circ \to \mathcal{C}^\circ
\]

is an operadic \( q \)-colimit diagram. This follows from our assumption that \( A(\mathcal{M}^\circ \times_{\Delta^2} \Delta^{(0,1)}) \) is an operadic \( q \)-left Kan extension.

Since \( A(\mathcal{M}^\circ \times_{\Delta^2} \Delta^{(0,1)}) \), the restriction of \( \theta \) to \( \mathcal{Y}^p \) is an operadic \( q \)-colimit diagram. The inclusion \( \mathcal{Y} \to \mathcal{Z}_{\circ_Y} \mathcal{Y} \) is a pushout of the inclusion \( \mathcal{Z} \times \{1\} \subseteq \mathcal{Z} \times \Delta^1 \), and therefore left cofinal. It follows that \( \theta \) itself is an operadic \( q \)-colimit diagram. Invoking Lemma 3.1.4.3, we conclude that \( \phi \circ \psi \) is an operadic \( q \)-colimit diagram, as desired.

\[\square\]

### 3.2 Limits and Colimits of Algebras

Let \( \mathcal{C}^\circ \) be a symmetric monoidal \( \infty \)-category and \( \mathcal{O}^\circ \) an arbitrary \( \infty \)-operad. In §2.1.3, we introduced the \( \infty \)-category \( \text{Alg}_\mathcal{O}(\mathcal{C}) \) of \( \mathcal{O} \)-algebra objects of \( \mathcal{C} \). Our goal in this section is to study these \( \infty \)-categories in more detail. In particular, we will study conditions which guarantee the existence (and allow for the computation of) limits and colimits in \( \text{Alg}_\mathcal{O}(\mathcal{C}) \). We begin in §3.2.2 with the study of limits in \( \text{Alg}_\mathcal{O}(\mathcal{C}) \). This is fairly straightforward: the basic result is that limits in \( \text{Alg}_\mathcal{O}(\mathcal{C}) \) can usually be computed in the underlying \( \infty \)-category \( \mathcal{C} \) (Proposition 3.2.2.1).

The study of colimits is much more involved. First of all, we do not expect colimits in \( \text{Alg}_\mathcal{O}(\mathcal{C}) \) to be computed in the underlying \( \infty \)-category \( \mathcal{C} \) in general. This is often true for colimits of a special type (for example, colimits of diagrams indexed by sifted simplicial sets), provided that the tensor product functor \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) behaves well with respect to colimits. The case of general colimits is more difficult. For example, if \( A \) and \( B \) are objects of \( \text{Alg}_\mathcal{O}(\mathcal{C}) \), then it is in general difficult to describe the coproduct \( A \coprod B \) explicitly. We will sidestep this issue using the theory of free algebras developed in §3.1. Though it is difficult to construct colimits of algebras in general, it is often much easier to construct colimits of free algebras, since the free algebra functor preserves colimits (being a left adjoint). In §3.2.3 we will exploit this observation to construct general colimits in \( \text{Alg}_\mathcal{O}(\mathcal{C}) \): the basic idea is to resolve arbitrary algebras with free algebras. Although this strategy leads to a fairly general existence result (Corollary 3.2.3.3), it
is somewhat unsatisfying because it does not usually give a direct description of the colimit of a diagram \( K \to \text{Alg}_\Omega(C) \). However, we can often say more for specific choices of the \( \infty \)-operad \( \mathcal{O}^\otimes \). For example, if \( \mathcal{O}^\otimes \) is the commutative \( \infty \)-operad \( \text{Comm}^\otimes = \text{N}(\text{Fin}_*) \), then it is easy to construct finite coproducts in the \( \infty \)-category \( \text{Alg}_\Omega(C) = \text{CAlg}(\mathcal{C}) \): these are simply given by tensor products in the underlying \( \infty \)-category \( \mathcal{C} \). We will prove this in §3.2.4 (Proposition 3.2.4.7), after giving a general discussion of tensor products of algebras. For coproducts of empty collections, we can be more general: there is an easy construction for initial objects of \( \text{Alg}_\Omega(C) \) whenever the \( \infty \)-operad \( \mathcal{O}^\otimes \) is unital. We will describe this construction in §3.2.1.

### 3.2.1 Unit Objects and Trivial Algebras

Let \( \mathcal{C} \) be a unit object of \( \text{Alg}_\Omega(C) \). Let \( \mathcal{O} \in \mathcal{C} \), and let \( f : C_0 \to 1_X \) be a morphism in \( \mathcal{C} \), where \( 1_X \in \mathcal{C}_X \). We will say that \( f \) exhibits \( 1_X \) as an \( X \)-unit object if the following conditions are satisfied:

1. The object \( C_0 \) belongs to \( \mathcal{C}^{\otimes(0)} \).
2. The morphism \( f \) is given by an operadic \( p \)-colimit diagram \( \Delta^1 \simeq (\mathcal{D}^0)^\triangleright \to \mathcal{C}^\otimes \).

More generally, we will say that an arbitrary morphism \( C_0 \to C \) in \( \mathcal{C}^\otimes \) exhibits \( C \) as a unit object if, for every inert morphism \( C \to C' \) with \( C' \in \mathcal{C} \), the composite map \( C_0 \to C' \) exhibits \( C' \) as a \( \mathcal{D}(C') \)-unit object. Suppose that \( \mathcal{D} \) is a unital \( \infty \)-operad. We will say that a fibration of \( \infty \)-operads \( \mathcal{D}^\otimes \to \mathcal{O}^\otimes \) has unit objects if, for every object \( X \in \mathcal{O}^\otimes \), there exists a morphism \( f : C_0 \to 1_X \) in \( \mathcal{O}^\otimes \) which exhibits \( 1_X \) as an \( X \)-unit object.

**Remark 3.2.1.2.** The terminology of Definition 3.2.1.1 is slightly abusive: the condition that a morphism \( f : C_0 \to C \) exhibits \( C \) as a unit object of \( \mathcal{C}^\otimes \) depends not only on the \( \infty \)-operad \( \mathcal{C}^\otimes \), but also on the \( \infty \)-operad fibration \( \mathcal{C}^\otimes \to \mathcal{O}^\otimes \).

**Remark 3.2.1.3.** Let \( p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads. If \( X \in \mathcal{O} \) and \( f : C_0 \to C \) is a morphism in \( \mathcal{C}^\otimes \) which exhibits \( C \) as a unit object, then \( f \) is \( p \)-coCartesian: this follows immediately from Proposition 3.1.1.10.

**Remark 3.2.1.4.** Let \( p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads, and assume that \( \mathcal{O}^\otimes \) is unital. Let \( \mathcal{X} \) denote the full subcategory of \( \text{Fun}(\Delta^1, \mathcal{C}^\otimes) \) spanned by those morphisms \( f : C_0 \to C \) which exhibit \( C \) as a unit object. Then the composite map

\[
\phi : \mathcal{X} \subseteq \text{Fun}(\Delta^1, \mathcal{C}^\otimes) \to \text{Fun}(\{1\}, \mathcal{C}^\otimes) \overset{p}{\to} \mathcal{O}^\otimes
\]

induces a trivial Kan fibration onto a full subcategory of \( \mathcal{O}^\otimes \). To see this, we let \( \mathcal{X}' \) denote the full subcategory of \( \text{Fun}(\Delta^1, \mathcal{C}^\otimes) \) spanned by those morphisms \( f : C_0 \to C \) which are \( p \)-coCartesian and satisfy \( C_0 \in \mathcal{C}^{\otimes(0)} \). Proposition T.4.3.2.15 implies that the map

\[
\mathcal{X}' \to \mathcal{C}^{\otimes(0)} \times_{\text{Fun}(\{0\}, \mathcal{O}^\otimes)} \text{Fun}(\Delta^1, \mathcal{O}^\otimes)
\]

is a trivial Kan fibration onto a full subcategory of the fiber product \( \mathcal{X}'' = \mathcal{C}^{\otimes(0)} \times_{\text{Fun}(\{0\}, \mathcal{O}^\otimes)} \text{Fun}(\Delta^1, \mathcal{O}^\otimes) \). Since \( \mathcal{C}^{\otimes(0)} \to \mathcal{O}^{\otimes(0)} \) is a categorical fibration between contractible Kan complexes, it is a trivial Kan fibration; it follows that the induced map \( \mathcal{X}'' \to \mathcal{O}^{\otimes(0)} \times_{\text{Fun}(\{0\}, \mathcal{O}^\otimes)} \text{Fun}(\Delta^1, \mathcal{O}^\otimes) \) is also a trivial Kan fibration. The
target of this map can be identified with the ∞-category \( O_\otimes \) of pointed objects of \( O_\otimes \), and the forgetful functor \( O_\otimes \to O_\otimes \) is a trivial Kan fibration because \( O_\otimes \) is unital. The desired result now follows by observing that φ is given by the composition

\[ X \subseteq X' \to X'' \to O_\otimes \to O_\otimes. \]

We can summarize our discussion as follows: if \( f : C_0 \to C \) is a morphism in \( C_\otimes \) which exhibits \( C \) as a unit object, then \( f \) is determined (up to canonical equivalence) by the object \( p(C) \in O_\otimes \). We observe that \( C_\otimes \to O_\otimes \) has unit objects if and only if the functor \( \phi \) above is essentially surjective. In this case the inclusion \( X \to X' \) must also be essentially surjective: in other words, a morphism \( f : C_0 \to C \) exhibits \( C \) as a unit object if and only if \( f \) is \( p \)-coCartesian and \( C_0 \in C_{\otimes (0)} \).

**Remark 3.2.1.5.** It is easy to see that the essential image of the functor \( \phi \) of Remark 3.2.1.4 is stable under the concatenation functor \( \oplus \) of Remark 2.2.4.6. Consequently, to show that a fibration of \( \infty \)-operads \( C_\otimes \to O_\otimes \) has unit objects, it suffices to show that for every object \( X \in O \) there exists a map \( f : C_0 \to 1_X \) which exhibits \( 1_X \) as an \( X \)-unit object of \( C \).

**Example 3.2.1.6.** Let \( p : C_\otimes \to O_\otimes \) be a coCartesian fibration of \( \infty \)-operads, where \( O_\otimes \) is unital. Then \( p \) has unit objects. This follows immediately from Proposition 3.1.1.20 and Remark 3.2.1.5.

**Definition 3.2.1.7.** Let \( p : C_\otimes \to O_\otimes \) be a fibration of \( \infty \)-operads, and assume that \( O_\otimes \) is unital. We will say that an algebra object \( A \in Alg_{/ O}(C) \) is **trivial** if, for every object \( X \in O_\otimes \), the induced map \( A(0) \to A(X) \) exhibits \( A(X) \) as a unit object; here \( 0 \) denotes the zero object of \( O_\otimes \).

When trivial algebra objects exist, they are precisely the initial objects of \( Alg_{/ O}(C) \):

**Proposition 3.2.1.8.** Let \( p : C_\otimes \to O_\otimes \) be a fibration of \( \infty \)-operads, where \( O_\otimes \) is unital. Assume that \( p \) has unit objects. The following conditions on a \( O \)-algebra object \( A \in Alg_{/ O}(C) \) are equivalent:

1. The object \( A \) is an initial object of \( Alg_{/ O}(C) \).
2. The functor \( A \) is a \( p \)-left Kan extension of \( A | O_{\otimes (0)} \).
3. The algebra object \( A \) is trivial.

**Corollary 3.2.1.9.** Let \( C_\otimes \) be a symmetric monoidal \( \infty \)-category. Then the \( \infty \)-category \( CA_{\otimes}(C) \) has an initial object. Moreover, a commutative algebra object \( A \) of \( C \) is an initial object of \( CA_{\otimes}(C) \) if and only if the unit map \( 1 \to A \) is an equivalence in \( C \).

The proof of Proposition 3.2.1.8 depends on the following:

**Lemma 3.2.1.10.** Let \( p : C_\otimes \to O_\otimes \) be a fibration of \( \infty \)-operads, where \( O_\otimes \) is unital. The following conditions are equivalent:

1. The fibration \( p \) has unit objects.
2. There exists a trivial \( O \)-algebra object \( A \in Alg_{/ O}(C) \).

**Proof.** The implication (2) \( \Rightarrow \) (1) follows immediately from Remark 3.2.1.5. Conversely, suppose that (1) is satisfied. Choose an arbitrary section \( s \) of the trivial Kan fibration \( C_{\otimes (0)} \to O_{\otimes (0)} \). Since \( p \) has units, Lemma T.4.3.2.13 (and Remark 3.2.1.3) imply that \( s \) admits a \( p \)-left Kan extension \( A : O_{\otimes (0)} \to C_{\otimes} \). For every morphism \( f : X \to Y \) in \( O_\otimes \), we have a commutative diagram

\[ \begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{g} & & \downarrow{h} \\
0 & \xrightarrow{h} & Y 
\end{array} \]

in \( O_\otimes \). Since \( A(g) \) and \( A(h) \) are \( p \)-coCartesian morphisms of \( C_\otimes \), Proposition T.2.4.1.7 implies that \( A(f) \) is \( p \)-coCartesian. It follows in particular that \( A \) preserves inert morphisms, so that \( A \in Alg_{/ O}(C) \). Using Remark 3.2.1.4, we conclude that \( A \) is trivial. \( \square \)
Proof of Proposition 3.2.1.8. The implication (2) ⇒ (3) follows from the proof of Lemma 3.2.1.10, and (3) ⇒ (2) follows immediately from Remark 3.2.1.3. The implication (2) ⇒ (1) follows from Proposition T.4.3.2.17 (since the ∞-category of sections of the trivial Kan fibration $\mathcal{C} \otimes \langle 0 \rangle \to \mathcal{O} \otimes \langle 0 \rangle$ is a contractible Kan complex). The reverse implication (1) ⇒ (2) follows from the uniqueness of initial objects up to equivalence, since Lemma 3.2.1.10 guarantees the existence of an object $A \in \text{Alg}_{/\mathcal{C}}(\mathcal{C})$ satisfying (3) (and therefore (2) and (1) as well).

### 3.2.2 Limits of Algebras

Let $\mathcal{C}$ be a symmetric monoidal category, and let $A$ and $B$ be commutative algebra objects of $\mathcal{C}$. Assume that the objects $A, B \in \mathcal{C}$ admit a product $A \times B \in \mathcal{C}$. The diagram

$$B \leftarrow B \otimes B \leftarrow (A \times B) \otimes (A \times B) \rightarrow A \otimes A \rightarrow A$$

determines a multiplication map $(A \times B) \otimes (A \times B) \rightarrow A \times B$. This multiplication determines a commutative algebra structure on $A \times B$. In fact, $A \times B$ can be identified with the product of $A$ and $B$ both in the underlying category $\mathcal{C}$ and in the category $\text{CAlg}(\mathcal{C})$ of commutative algebra objects of $\mathcal{C}$.

In this section, we will generalize the above observation in several ways:

(a) We work in the setting of ∞-categories, rather than ordinary categories.

(b) In place of commutative algebra objects, we will study $\mathcal{O}$-algebra objects for an arbitrary ∞-operad $\mathcal{O}^\otimes$.

(c) We work with limits indexed by arbitrary diagrams, rather than merely Cartesian products.

(d) Rather than considering limits in a fixed symmetric monoidal ∞-category $\mathcal{C}$, we consider relative limits with respect to a fibration of ∞-operads $\mathcal{C}^\otimes \to \mathcal{D}^\otimes$.

We can state our main result as follows:

**Proposition 3.2.2.1.** Let $\mathcal{O}^\otimes$ be an ∞-operad, let $p : \mathcal{C}^\otimes \to \mathcal{D}^\otimes$ be a fibration of ∞-operads, and suppose we are given a commutative diagram

$$\begin{array}{ccc}
K & \overset{f}{\longrightarrow} & \text{Alg}_\mathcal{O}(\mathcal{C}) \\
\downarrow & & \downarrow \quad \scriptstyle{q} \\
K^\otimes & \overset{g}{\longrightarrow} & \text{Alg}_\mathcal{O}(\mathcal{D}).
\end{array}$$

Assume that for every object $X \in \mathcal{O}$, the induced diagram

$$\begin{array}{ccc}
K & \overset{fx}{\longrightarrow} & \mathcal{C} \\
\downarrow \scriptstyle{fx} & & \downarrow \quad \scriptstyle{\mathcal{F}_X} \\
K^\otimes & \longrightarrow & \mathcal{D}
\end{array}$$

admits an extension as indicated, where $\mathcal{F}_X$ is a $p$-limit diagram. Then:

1. **There exists an extension** $\mathcal{F} : K^\otimes \rightarrow \text{Alg}_\mathcal{O}(\mathcal{C})$ **of** $f$ **which is compatible with** $g$, **such that** $\mathcal{F}$ **is a** $q$-limit diagram.

2. **Let** $\mathcal{F} : K^\otimes \rightarrow \text{Alg}_\mathcal{O}(\mathcal{C})$ **be an arbitrary extension of** $f$ **which is compatible with** $g$. **Then** $\mathcal{F}$ **is a** $q$-limit diagram if and only if for every object $X \in \mathcal{O}$, the induced map $\mathcal{F}_X : K^\otimes \rightarrow \mathcal{C}$ is a $p$-limit diagram.
Warning 3.2.2.2. Let $\overline{f} : K^d \to \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ be as in part (2) of Proposition 3.2.2.1, and let $X \in \mathcal{O}$. Although the map $\overline{f}_X$ takes values in $\mathcal{C} \subseteq \mathcal{O}^\otimes$, the condition that $\overline{f}_X$ be a $p$-limit diagram is generally stronger than the condition that $\overline{f}_X$ be a $p_0$-limit diagram, where $p_0 : \mathcal{O} \to \mathcal{D}$ denotes the restriction of $p$.

In spite of Warning 3.2.2.2, the criterion of Proposition 3.2.2.1 can be simplified if we are willing to restrict our attention to the setting of $\infty$-operads admitting a coCartesian fibration to $\mathcal{O}^\otimes$.

Corollary 3.2.2.3. Suppose we are given a commutative diagram

\[
\begin{array}{ccc}
\mathcal{C}^\otimes & \xrightarrow{p} & \mathcal{D}^\otimes \\
\downarrow & & \downarrow \\
\mathcal{O}^\otimes & & \\
\end{array}
\]

where $p$ is a fibration of $\infty$-operads and the vertical maps are coCartesian fibrations of $\infty$-operads. Suppose given a commutative diagram

\[
\begin{array}{ccc}
K & \xrightarrow{f} & \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \\
\downarrow & & \downarrow \\
K^d & \xrightarrow{g} & \text{Alg}_{/\mathcal{O}}(\mathcal{D}) \\
\end{array}
\]

such that, for every object $X \in \mathcal{O}$, the induced diagram

\[
\begin{array}{ccc}
K & \xrightarrow{f_X} & \mathcal{C}_X \\
\downarrow & & \downarrow \\
K^d & \xrightarrow{\overline{f}_X} & \mathcal{D}_X \\
\end{array}
\]

admits an extension as indicated, where $\overline{f}_X$ is a $p_X$-limit diagram. Then:

1. There exists an extension $\overline{f} : K^d \to \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ of $f$ which is compatible with $g$, such that $\overline{f}$ is a $q$-limit diagram.

2. Let $\overline{f} : K^d \to \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ be an arbitrary extension of $f$ which is compatible with $g$. Then $\overline{f}$ is a $q$-limit diagram if and only if for every object $X \in \mathcal{O}$, the induced map $K^d \to \mathcal{C}_X$ is a $p_X$-limit diagram.

Proof. Combine Proposition 3.2.2.1 with Corollary T.4.3.1.15.

Passing to the case $\mathcal{D}^\otimes = \mathcal{O}^\otimes$, we obtain the following result:

Corollary 3.2.2.4. Let $p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a coCartesian fibration of $\infty$-operads, and let $q : K \to \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ be a diagram. Suppose that, for every object $X \in \mathcal{O}$, the induced diagram $q_X : K \to \mathcal{C}_X$ admits a limit. Then:

1. The diagram $q : K \to \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ admits a limit.

2. An extension $\overline{q} : K^d \to \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ of $q$ is a limit diagram if and only if the induced map $\overline{q}_X : K^d \to \mathcal{C}_X$ is a limit diagram for each $X \in \mathcal{O}$.

Corollary 3.2.2.5. Let $p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a coCartesian fibration of $\infty$-operads and let $K$ be a simplicial set. Suppose that, for every object $X \in \mathcal{O}^\otimes$, the fiber $\mathcal{C}_X$ admits $K$-indexed limits. Then:

1. The $\infty$-category $\text{Alg}_{/\mathcal{O}}(\mathcal{C})$ admits $K$-indexed limits.
(2) An arbitrary diagram $K^\circ \to \text{Alg}_{/O}(\mathcal{C})$ is a limit diagram if and only the composite diagram

$$K^\circ \to \text{Alg}_{/O}(\mathcal{C}) \to \mathcal{C}_X$$

is a limit, for each $X \in O$.

In particular, for each $X \in O$ the evaluation functor $\text{Alg}_{/O}(\mathcal{C}) \to \mathcal{C}_X$ preserves $K$-indexed limits.

We now turn to the proof of Proposition 3.2.2.1. We need some preliminaries.

**Lemma 3.2.2.6.** Let $p : \mathcal{E}^0 \to \mathcal{O}^0$ be a fibration of $\infty$-operads, and let $\gamma : A \to A'$ be a morphism in $\text{Alg}_{/O}(\mathcal{C})$. The following conditions are equivalent:

(1) The morphism $\gamma$ is an equivalence in $\text{Alg}_{/O}(\mathcal{C})$.

(2) For every object $X \in O$, the morphism $\gamma(X) : A(X) \to A'(X)$ is an equivalence in $\mathcal{C}$.

**Proof.** The implication $(1) \Rightarrow (2)$ is obvious. Conversely, suppose that $(2)$ is satisfied. Let $X \in \mathcal{O}^0_{(n)}$; we wish to prove that $\gamma(X)$ is an equivalence in $\mathcal{E}^0_{(n)}$. Since $\mathcal{E}^0$ is a symmetric monoidal $\infty$-category, it suffices to show that for every $1 \leq j \leq n$, the image of $\gamma(X)$ under the functor $\rho^j : \mathcal{E}^0_{(n)} \to \mathcal{C}$ is an equivalence. Since $A$ and $A'$ are maps of $\infty$-operads, this morphism can be identified with $\gamma(X_j)$ where $X_j$ is the image of $X$ under the corresponding functor $\mathcal{O}^0_{(n)} \to \mathcal{O}$. The desired result now follows immediately from $(2)$. \qed

**Lemma 3.2.2.7.** Let $p : \mathcal{D} \to \mathcal{C}$ be a right fibration of $\infty$-categories, let $\mathcal{E}^0 \subseteq \mathcal{C}$ be a full subcategory, and let $\mathcal{D}^0 = \mathcal{E}^0 \times_{\mathcal{C}} \mathcal{D}$. Let $q : X \to S$ be a categorical fibration of simplicial sets, and let $F : \mathcal{E} \to X$ be a map which is a $q$-left Kan extension of $F|\mathcal{E}^0$. Then $F \circ p$ is a $q$-left Kan extension of $F \circ p|\mathcal{D}^0$.

**Proof.** Let $D$ be an object of $\mathcal{D}$, $C = p(D)$, and define

$$\mathcal{E}^0_{/C} = \mathcal{E}^0 \times_{\mathcal{C}} \mathcal{D}^0_{/D} = \mathcal{D}^0 \times_{\mathcal{D}} \mathcal{D}^0_{/D}.$$  

We wish to show that the composition

$$(\mathcal{D}^0_{/D})^p \to (\mathcal{E}^0_{/C})^p \to \mathcal{E}^0 \to X$$

is a $q$-colimit diagram. Since $F$ is a $q$-left Kan extension of $F|\mathcal{E}^0$, it will suffice to show that the map $\phi_0 : \mathcal{D}^0_{/D} \to \mathcal{E}^0_{/C}$ is a trivial Kan fibration. The map $\phi_0$ is a pullback of the map $\phi : \mathcal{D}^0_{/D} \to \mathcal{E}^0_{/C}$, which is a trivial Kan fibration by Proposition T.2.1.2.5. \qed

**Lemma 3.2.2.8.** Let $p : X \to S$ and $q : Y \to Z$ be maps of simplicial sets. Assume that $q$ is a categorical fibration, and that $p$ is a flat categorical fibration.

Define new simplicial sets $Y'$ and $Z'$ equipped with maps $Y' \to S$, $Z' \to S$ via the formulas

$$\text{Hom}_S(K,Y') \simeq \text{Hom}(X \times_S K, Y)$$

$$\text{Hom}_S(K,Z') \simeq \text{Hom}(X \times_S K, Z).$$

Let $\mathcal{E}'$ be an $\infty$-category equipped with a functor $f : \mathcal{E}' \to Y'$, and let $\mathcal{E}$ be a full subcategory of $\mathcal{E}'$. Then:

(1) Composition with $q$ determines a categorical fibration $q' : Y' \to Z'$.

(2) Let $F : X \times_S \mathcal{E}' \to Y$ be the map classified by $f$, and suppose that $F$ is a $q$-left Kan extension of $F|X \times_S \mathcal{E}$. Then $f$ is a $q'$-left Kan extension of $f|\mathcal{E}$. 

Proof. We first prove (1). We wish to show that $q'$ has the right lifting property with respect to every inclusion $i : A \to B$ of simplicial sets which is a categorical equivalence. For this, it suffices to show that $q$ has the right lifting property with respect to every inclusion of the form $i' : X \times_S A \to X \times_S B$. Since $q$ is a categorical fibration, it suffices to prove that $i'$ is a categorical equivalence, which follows from Corollary B.3.15.

We now prove (2). Let $C$ be an object of $C'$, and let $C_{/C}$ denote the fiber product $C \times_C C'$. We wish to show that the composition

$$C_{/C} \to C' \xrightarrow{F} Y'$$

is a $q'$-colimit diagram. Replacing $C \subseteq C'$ by the inclusion $C_{/C} \subseteq C'_{/C}$ (and applying Lemma 3.2.2.7), we can reduce to the case $C' = C_{/C}$.

Let $n > 0$, and suppose we are given a diagram

$$\begin{array}{ccc}
C \times \partial \Delta^n & \xrightarrow{f'} & Y' \\
\downarrow & & \downarrow q' \\
C \times \Delta^n & \xrightarrow{g} & Z',
\end{array}$$

where $f'|C \{0\}$ coincides with $f$. We wish to show that there exists a dotted arrow, as indicated in the diagram. Composing $g$ with the map $Z' \to S$, we obtain a map $C \times \Delta^n \to S$. Let $D$ denote the fiber product $X \times_S (C \times \Delta^n)$, and let $D^0 = X \times_S (C \times \partial \Delta^n)$. Unwinding the definitions, we are reduced to solving a lifting problem depicted in the diagram

$$\begin{array}{ccc}
D^0 & \xrightarrow{F_0} & Y \\
\downarrow & & \downarrow q \\
D & \xrightarrow{G} & Z.
\end{array}$$

Let $D'$ denote the inverse image of $\Delta^n$ in $D$, and let $D'_0 = D' \times \Delta^n \partial \Delta^n$. Let $A$ be the collection of all (possibly degenerate) simplices of $D'$ which do not belong to $D'_0$. For every nondegenerate simplex $\sigma : \Delta^m \to D$ which does not belong to $D^0$, let $i$ be the smallest integer such that $\sigma(i) \in D'$ and set $r(\sigma) = \sigma|\Delta^m \setminus \sigma(i)$. Note that $r(\sigma)$ is an element of $A$ (though $r(\sigma)$ may be degenerate).

Choose a well ordering of $A$ with the following property: if $\sigma, \tau \in A$ are simplices such that the dimension of $\sigma$ is smaller than the dimension of $\tau$, then $\sigma < \tau$. Let $\alpha$ be the order type of the well-ordering of $A$, so we have an order-preserving bijection $\{\beta < \alpha\} \approx A$ given by $\beta \mapsto \sigma_\beta$. For $0 \leq \beta \leq \alpha$, let $D^\beta$ denote the simplicial subset of $D$ spanned by $D^0$ together with those nondegenerate simplices $\sigma$ such that $r(\sigma) = \sigma_\gamma$ for some $\gamma < \beta$. Note that when $\beta = 0$, this agrees with our previous definition of $D^0$. We will construct a compatible family of maps $F_\beta : D^\beta \to Y$ which extend $F_0$ and satisfy $q \circ F_\beta = G|D^\beta$. Taking $F = F_\alpha$, we obtain a proof of the desired result.

It remains to construct the maps $F_\beta$. We proceed by induction on $\beta$. If $\beta$ is a limit ordinal, we take $F_\beta = \bigcup_{\gamma < \beta} F_\gamma$. It therefore suffices to treat the case of successor ordinals. Assume therefore that $F_\beta$ has been defined; we wish to construct the map $F_{\beta + 1}$. Let $\sigma = \sigma_\beta : \Delta^m \to D'$ be the corresponding simplex. Note that the induced map $\Delta^m \to \Delta^n$ is surjective, so we automatically have $m > 0$. We first treat the case where the simplex $\sigma$ is nondegenerate. Let $E$ denote the fiber product $D_{/\sigma} \times_C \partial \Delta^n C$, so that we have a pushout diagram of simplicial sets

$$\begin{array}{ccc}
E \times \partial \sigma & \to & D^\beta \\
\downarrow & & \downarrow \\
E \times \sigma & \to & D^{\beta + 1}.
\end{array}$$
We are therefore reduced to solving the lifting problem depicted in the diagram

\[
\begin{array}{ccc}
\mathcal{E} \times \partial \sigma & \xrightarrow{h} & Y \\
\downarrow q & & \downarrow \\
\downarrow & & \\
\mathcal{E} \times \sigma & \xrightarrow{\Delta m} & Z.
\end{array}
\]

Let \( h' \) denote the restriction of \( h \) to \( \mathcal{E} \times \{v\} \), where \( v \) is the initial vertex of \( \sigma \). Our assumption on \( F_0 \) guarantees that \( h' \) is a \( q \)-colimit diagram, so that the above lifting problem admits a solution.

We now treat the case where the simplex \( \sigma \) is degenerate. In this case, we will prove the existence of \( F_{\beta+1} \) by showing that the inclusion \( i : D^\beta \to D^{\beta+1} \) is a categorical equivalence. Let \( \mathcal{J} \) be the category whose objects are diagrams

\[
\begin{array}{ccc}
\Delta^{m'} & \xrightarrow{\sigma'} & D' \\
\downarrow u & & \downarrow \\
\Delta^m & \xrightarrow{\sigma} & D'
\end{array}
\]

where \( u \) is surjective and \( m' < m \). Let \( H : \mathcal{J}^{op} \to \text{Set}_\Delta \) be the functor which carries the above diagram to the simplicial set \( D_{/\sigma'} \times_{\mathcal{E} \times \Delta^n} \mathcal{E} \). We note that \( i \) is a pushout of the inclusion

\[
(\lim_{\rightarrow} (H) \times \sigma) \coprod_{\lim_{\rightarrow} (H) \times \partial \sigma} (\mathcal{E} \times \partial \sigma) \rightarrow \mathcal{E} \times \sigma.
\]

Consequently, to prove that \( i \) is a categorical equivalence, it suffices to show that the diagram

\[
\begin{array}{ccc}
\lim_{\rightarrow} (H) \times \partial \sigma & \to & \mathcal{E} \times \partial \sigma \\
\downarrow & & \downarrow \\
\lim_{\rightarrow} (H) \times \sigma & \to & \mathcal{E} \times \sigma
\end{array}
\]

We claim that the horizontal arrows in this diagram are categorical equivalences. To prove this, it suffices to verify that the canonical map \( j : \lim_{\rightarrow} (H) \to \mathcal{E} \) is a categorical equivalence. Since \( H \) is a projectively cofibrant diagram, it suffices to show that \( j \) exhibits \( \mathcal{E} \) as a homotopy colimit of \( H \) (with respect to the Joyal model structure). Note that the category \( \mathcal{J} \) has a final object, corresponding to a diagram in which the map \( \sigma' : \Delta^{m'} \to D' \) is a nondegenerate simplex of \( D' \). Consequently, it will suffice to \( H \) is weakly equivalent to the constant diagram taking the value \( \mathcal{E} \). In other words, we are reduced to proving that for every diagram

\[
\begin{array}{ccc}
\Delta^{m'} & \xrightarrow{\sigma'} & D' \\
\downarrow u & & \downarrow \\
\Delta^m & \xrightarrow{\sigma} & D'
\end{array}
\]

belonging to \( \mathcal{E} \), the induced map

\[
D_{/\sigma'} \times_{\mathcal{E} \times \Delta^n} \mathcal{E} \to D_{/\sigma} \times_{\mathcal{E} \times \Delta^n} \mathcal{E}
\]

is a categorical equivalence. This is clear, since both sides are equivalent to \( D_{/v} \times_{\mathcal{E} \times \Delta^n} \mathcal{E} \), where \( v \) is the initial vertex of \( \sigma \).

\[\Box\]

Lemma 3.2.2.9. Let \( p : \mathcal{C} \to \mathcal{D} \) be a categorical fibration of \( \infty \)-categories, let \( \mathcal{E} \) and \( K \) be simplicial sets, and suppose given a diagram

\[
\begin{array}{ccc}
K \times \mathcal{E} & \xrightarrow{f} & \mathcal{E} \\
\downarrow \gamma & & \downarrow p \\
K^\alpha \times \mathcal{E} & \xrightarrow{p} & \mathcal{D}.
\end{array}
\]

Suppose further that for each vertex $E$ of $E$, there exists an extension $f_E : K^a \to \mathcal{C}$ of $f_E$ which is compatible with the above diagram and is a $p$-limit. Then:

1. There exists a map $\overline{f} : K^a \times E \to \mathcal{C}$ rendering the above diagram commutative, with the property that for each vertex $E$ of $E$, the induced map $\overline{f}_E : K^a \to \mathcal{C}$ is a $p$-limit diagram.

2. Let $\overline{f} : K^a \times E \to \mathcal{C}$ be an arbitrary map which renders the above diagram commutative. Then $\overline{f}$ satisfies the condition of (1) if and only if the adjoint map $K^a \to \text{Fun}(\mathcal{E}, \mathcal{C})$ is a $p\mathcal{C}$-limit diagram, where $p\mathcal{C} : \text{Fun}(\mathcal{E}, \mathcal{C}) \to \text{Fun}(\mathcal{E}, \mathcal{D})$ is given by composition with $p$.

Proof. Without loss of generality, we may suppose that $E$ and $K$ are $\infty$-categories. Let $\infty$ denote the cone point of $K^a$. For each object $E \in \mathcal{E}$, the inclusion $K \times \{\text{id}_E\} \subseteq K \times \mathcal{E}/ \simeq (K \times \mathcal{E})/\langle \infty, E\rangle$ is left anodyne. Consequently, $\overline{f}$ satisfies (1) if and only if $\overline{f}$ is a $p$-right Kan extension of $f'$. The existence of $\overline{f}$ follows from Lemma T.4.3.2.13.

The “only if” direction of (2) follows immediately from Lemma 3.2.2.8. The converse follows from the uniqueness of limits (up to equivalence). \qed

Proof of Proposition 3.2.2.1. We first establish the following:

(*) Let $h : K^a \to \mathcal{C}_{(n)}$ be a diagram, and for $1 \leq i \leq n$ let $h_i$ denote the image of $h$ under the functor $\rho_i : \mathcal{C}_{(n)} \to \mathcal{C}$. If each $h_i$ is a $p$-limit diagram, then $h$ is a $p$-limit diagram.

To prove (*), we observe that there are natural transformations $h \to h_i$ which together determine a map $H : K^a \times \langle n \rangle^a \to \mathcal{C}^\otimes$. Since the restriction of $H$ to $K^a \times \{i\}$ is a $p$-limit diagram for $1 \leq i \leq n$ and the restriction of $H$ to $\{v\} \times \langle n \rangle^a$ is a $p$-limit diagram for all vertices $v$ in $K^a$ (Remark 2.1.2.11), we deduce from Lemma T.5.5.2.3 that $h$ is a $p$-limit diagram as desired.

We now prove the “if” direction of (2). Suppose that $\overline{f} : K^a \to \text{Alg}_\mathcal{O}(\mathcal{C})$ induces a $p$-limit diagram $\overline{f}_X : K^a \to \mathcal{C}^\otimes$ for each $X \in \mathcal{O}$. We claim that the same assertion holds for each $X \in \mathcal{O}$. To prove this, let $\langle n \rangle$ denote the image of $X$ in $N(\mathcal{F})$, and choose inert morphisms $X \to X_i$ in $\mathcal{O}^\otimes$ lifting $\rho_i : \langle n \rangle \to (1)$ for $1 \leq i \leq n$. The image of $\overline{f}_X$ under $\rho_i$ can be identified with $\overline{f}_{X_i}$, and is therefore a $p$-limit diagram; the desired result now follows from (*). Applying Lemma 3.2.2.9, we deduce that the diagram $\overline{f}$ is a $q'$-limit diagram, where $q'$ denotes the projection $\text{Fun}_{N(\mathcal{F})}(\mathcal{O}^\otimes, \mathcal{C}^\otimes) \to \text{Fun}_{N(\mathcal{F})}(\mathcal{O}^\otimes, \mathcal{D}^\otimes)$. Passing to the full subcategories $\text{Alg}_\mathcal{O}(\mathcal{C}) \subseteq \text{Fun}_{N(\mathcal{F})}(\mathcal{O}^\otimes, \mathcal{C}^\otimes) \quad \text{Alg}_\mathcal{O}(\mathcal{D}) \subseteq \text{Fun}_{N(\mathcal{F})}(\mathcal{O}^\otimes, \mathcal{D}^\otimes)$

we deduce that $\overline{f}$ is also a $q$-limit diagram, as desired.

We now prove (1). Choose a categorical equivalence $i : K \to K'$, where $K'$ is an $\infty$-category and $i$ is a monomorphism. Since $\text{Alg}_\mathcal{O}(\mathcal{D})$ is an $\infty$-category and $q$ is a categorical fibration, we can assume that $f$ and $g$ factor through compatible maps $f' : K' \to \text{Alg}_\mathcal{O}(\mathcal{C})$ and $K'' \to \text{Alg}_\mathcal{O}(\mathcal{D})$. Using Proposition T.2.3.1, we deduce that the extension $\overline{f}$ exists if and only if there is an analogous extension of $f'$. We are therefore free to replace $K$ by $K'$ and reduce to the case where $K$ is an $\infty$-category. The map $f$ classifies a functor $F : K \times \mathcal{O} \to \mathcal{C}^\otimes$ and the map $g$ classifies a functor $G : K' \times \mathcal{O} \to \mathcal{C}^\otimes$. We first claim:

(\star) There exists an extension $\overline{F} : K \times \mathcal{O} \to \mathcal{C}^\otimes$ of $F$ lying over $G$ such that $\overline{F}$ is a $p$-right Kan extension of $F$.

Let $\nu$ denote the cone point of $K^a$. According to Lemma T.4.3.2.13, it suffices to show that for each object $X \in \mathcal{O}^\otimes$, the induced diagram $(K \times \mathcal{O}^\otimes)_{(\nu, X)} \simeq K \times \mathcal{O}^\otimes_{X^\otimes} \to \mathcal{C}^\otimes$ can be extended to a $p$-limit diagram compatible with $G$. Since the inclusion $K \times \{\text{id}_X\} \subseteq K \times \mathcal{O}_{X^\otimes}$ is right cofinal, it suffices to show that we can complete the diagram

\[
\begin{array}{ccc}
K & \xrightarrow{f_X} & \mathcal{C}^\otimes \\
\overline{F}_X & \downarrow & \downarrow \\
K^a & \xrightarrow{g_X} & \mathcal{D}^\otimes
\end{array}
\]
so that \( \mathcal{F}_X \) is a \( p \)-limit diagram. Let \( \langle n \rangle \) denote the image of \( X \) in \( N(\mathcal{F}_{\infty}) \). Since \( \mathcal{C} \) and \( \mathcal{D} \) are \( \infty \)-operads, we have a homotopy commutative diagram

\[
\begin{array}{ccc}
\mathcal{C}^{(n)} & \longrightarrow & \mathcal{C}^n \\
\downarrow & & \downarrow \\
\mathcal{D}^{(n)} & \longrightarrow & \mathcal{D}^n
\end{array}
\]

where the horizontal morphisms are categorical equivalences. Using Proposition T.A.2.3.1 and our assumption on \( f \), we deduce that \( f_X \) admits an extension \( \mathcal{F}_X \) (compatible with \( g_X \)) whose images under the functors \( \rho^\prime \) are \( p \)-limit diagrams in \( \mathcal{C} \). It follows from (*) that \( \mathcal{F}_X \) is a \( p \)-limit diagram, which completes the verification of (*'). Moreover, the proof shows that an extension \( \mathcal{F} \) of \( F \) (compatible with \( G \)) is a \( p \)-right Kan extension if and only if, for each \( X \in \mathcal{O} \), the functor \( \rho^\prime : \mathcal{C}^{\mathcal{O}(X)} \rightarrow \mathcal{C} \) carries \( \mathcal{F}(K^\Delta \times \{X\}) \) to a \( p \)-limit diagram in \( \mathcal{C} \).

Let \( s : \mathcal{O} \rightarrow \mathcal{C} \) be the functor obtained by restricting \( \mathcal{F} \) to the cone point of \( K^\Delta \). Then \( s \) preserves inert morphisms lying over the maps \( \rho^\prime : \langle n \rangle \rightarrow \langle 1 \rangle \) and is therefore a map of \( \infty \)-operads (Remark 2.1.2.9). It follows that \( \mathcal{F} \) determines an extension \( \mathcal{F} : K^\Delta \rightarrow \text{Alg}_{\mathcal{O}}(\mathcal{C}) \) of \( f \) lifting \( g \). The first part of the proof shows that \( \mathcal{F} \) is a \( q \)-limit diagram, which completes the proof of (1).

We conclude by proving the “only if” direction of (2). Let \( \mathcal{T} \) be a \( q \)-left Kan extension of \( f \) lying over \( g \). The proof of (1) shows that we can choose another \( q \)-left Kan extension \( \mathcal{T} \) of \( f \) lying over \( g \) such that \( \mathcal{T}_X : K^\Delta \rightarrow \mathcal{C} \) is a \( p \)-limit diagram for each \( X \in \mathcal{O} \). It follows that \( \mathcal{T} \) and \( \mathcal{T} \) are equivalent, so that each \( \mathcal{T}_X \) is also a \( p \)-limit diagram. \( \square \)

### 3.3.3 Colimits of Algebras

Let \( p : \mathcal{C} \rightarrow \mathcal{O} \) be a fibration of \( \infty \)-operads. Our goal in this section is to construct colimits in the \( \infty \)-category \( \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \), given suitable hypotheses on \( p \). Our strategy is as follows: we begin by constructing \( \text{sifted} \) colimits in \( \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \) (Proposition 3.2.3.1), which are given by forming colimits of the underlying objects in \( \mathcal{C} \). We will then combine this construction with existence results for free algebras (see §3.1.3) to deduce the existence of general colimits (Corollary 3.2.3.3).

Our first main result can be stated as follows:

**Proposition 3.2.3.1.** Let \( K \) be a sifted simplicial set and let \( p : \mathcal{C} \rightarrow \mathcal{O} \) be a \( \text{coCartesian} \) fibration of \( \infty \)-operads which is compatible with \( K \)-indexed colimits. Then:

1. The \( \infty \)-category \( \text{Fun}_{\mathcal{O}}(\mathcal{O}, \mathcal{C}) \) of sections of \( p \) admits \( K \)-indexed colimits.

2. A map \( \mathcal{F} : K^\mathcal{O} \rightarrow \text{Fun}_{\mathcal{O}}(\mathcal{O}, \mathcal{C}) \) is a colimit diagram if and only if, for each \( X \in \mathcal{O} \), the induced diagram \( \mathcal{F}_X : K^X \rightarrow \mathcal{C}^X \) is a colimit diagram.

3. The full subcategories
   \[
   \text{Fun}_{\mathcal{O}}(\mathcal{O}, \mathcal{C}) \subseteq \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \subseteq \text{Fun}_{\mathcal{O}}(\mathcal{O}, \mathcal{C})
   \]
   are stable under \( K \)-indexed colimits.

4. A map \( \mathcal{F} : K^\mathcal{O} \rightarrow \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \) is a colimit diagram if and only if, for each \( X \in \mathcal{O} \), the induced diagram \( \mathcal{F}_X : K^X \rightarrow \mathcal{C}_X \) is a colimit diagram.

We will give the proof of Proposition 3.2.3.1 at the end of this section.

**Corollary 3.2.3.2.** Let \( \mathcal{C} \) be a symmetric monoidal \( \infty \)-category, and let \( K \) be a sifted simplicial set such that the symmetric monoidal structure on \( \mathcal{C} \) is compatible with \( K \)-indexed colimits. Then:

1. The \( \infty \)-category \( \text{CAlg}(\mathcal{C}) \) admits \( K \)-indexed colimits.
(2) The forgetful functor \( \theta : CAlg(\mathcal{C}) \to \mathcal{C} \) detects \( K \)-indexed colimits. More precisely, a map \( \eta : K^p \to CAlg(\mathcal{C}) \) is a colimit diagram if and only if \( \theta \circ \eta \) is a colimit diagram.

Proof. Apply Proposition 3.2.3.1 in the case where \( O^\otimes \) is the commutative \( \infty \)-operad.

We now treat the case of more general colimits.

**Corollary 3.2.3.3.** Let \( \kappa \) be an uncountable regular cardinal and let \( O^\otimes \) be an essentially \( \kappa \)-small \( \infty \)-operad. Let \( p : C^\otimes \to O^\otimes \) be a coCartesian fibration of \( \infty \)-operads which is compatible with \( \kappa \)-small colimits. Then \( Alg_{/O}(\mathcal{C}) \) admits \( \kappa \)-small colimits.

Proof. Without loss of generality we may assume that \( O^\otimes \) is \( \kappa \)-small. In view of Corollary T.4.2.3.11 and Lemma 1.3.3.10, arbitrary \( \kappa \)-small colimits in \( Alg_{/O}(\mathcal{C}) \) can be built from \( \kappa \)-small filtered colimits, geometric realizations of simplicial objects, and finite coproducts. Since \( Alg_{/O}(\mathcal{C}) \) admits \( \kappa \)-small sifted colimits (Corollary 3.2.3.2), it will suffice to prove that \( Alg_{/O}(\mathcal{C}) \) admits finite coproducts.

According to Example 3.1.3.6, the forgetful functor \( G : Alg_{/O}(\mathcal{C}) \to Fun_0(\mathcal{O}, \mathcal{C}) \) admits a left adjoint which we will denote by \( F \). Let us say that an object of \( Alg_{/O}(\mathcal{C}) \) is free if it belongs to the essential image of \( F \). Since \( Fun_0(\mathcal{O}, \mathcal{C}) \) admits \( \kappa \)-small colimits and \( F \) preserves \( \kappa \)-small colimits (Proposition T.5.2.3.5), a finite collection of objects \( \{ A^i \} \) of \( Alg_{/O}(\mathcal{C}) \) admits a coproduct whenever each \( A^i \) is free.

We now claim the following:

\[ (*) \text{ For every object } A \in Alg_{/O}(\mathcal{C}), \text{ there exists a simplicial object } A_* \text{ of } Alg_{/O}(\mathcal{C}) \text{ such that } A \text{ is equivalent to the geometric realization } |A_*| \text{ and each } A_n \text{ is free.} \]

This follows from Proposition 4.7.4.14, since the forgetful functor \( G \) is conservative (Lemma 3.2.2.6) and commutes with geometric realizations (Corollary 3.2.3.2).

Now let \( \{ A^i \} \) be an arbitrary finite collection of objects of \( Alg_{/O}(\mathcal{C}) \); we wish to prove that \( A^i \) admits a coproduct in \( Alg_{/O}(\mathcal{C}) \). According to \((*)\), each \( A^i \) can be obtained as the geometric realization of a simplicial object \( A_*^i \) of \( Alg_{/O}(\mathcal{C}) \), where each \( A_n^i \) is free. It follows that the diagrams \( A_*^i \) admit a coproduct \( A_* : N(\Delta^{op}) \to Alg_{/O}(\mathcal{C}) \). Using Lemma T.5.5.2.3, we conclude that a geometric realization of \( A_* \) (which exists by virtue of Corollary 3.2.3.2) is a coproduct for the collection \( A^i \).

We next give a criterion for establishing that an \( \infty \)-category of algebras \( Alg_{/O}(\mathcal{C}) \) is presentable.

**Lemma 3.2.3.4.** Let \( O^\otimes \) be an essentially small \( \infty \)-operad, and let \( p : C^\otimes \to O^\otimes \) be a coCartesian fibration of \( \infty \)-operads. The following conditions are equivalent:

1. For each \( X \in O \), the fiber \( C_X \) is accessible, and \( p \) is compatible with \( \kappa \)-filtered colimits for \( \kappa \) sufficiently large.

2. Each fiber of \( p \) is accessible, and for every morphism \( f : X \to Y \) in \( O^\otimes \), the associated functor \( f_* : C_X^\otimes \to C_Y^\otimes \) is accessible.

**Proof.** The implication \((2) \Rightarrow (1)\) is obvious. Conversely, suppose that \((1)\) is satisfied. For each \( X \in O_{(m)} \), choose inert morphisms \( X \to X_i \) lying over \( \rho^i : \langle m \rangle \to \langle 1 \rangle \) for \( 1 \leq i \leq m \). Proposition 2.1.2.12 implies that \( C_X^\otimes \) is equivalent to the product \( \coprod_{1 \leq i \leq m} C_{X_i} \), which is accessible by virtue of \((1)\) and Lemma T.5.4.7.2. Now suppose that \( f : X \to Y \) is a morphism in \( O^\otimes \); we wish to prove that the functor \( f_* : C_X^\otimes \to C_Y^\otimes \) is accessible. This follows from \((1)\) and Lemma 3.2.3.7.

**Corollary 3.2.3.5.** Let \( p : C^\otimes \to O^\otimes \) be a coCartesian fibration of \( \infty \)-operads, where \( O^\otimes \) is essentially small. Assume that for each \( X \in O \), the fiber \( C_X \) is accessible.

1. If \( p \) is compatible with \( \kappa \)-filtered colimits for \( \kappa \) sufficiently large, \( Alg_{/O}(C) \) is an accessible \( \infty \)-category.
(2) Suppose that each fiber \( \mathcal{C}_X \) is presentable and that \( p \) is compatible with small colimits. Then \( \text{Alg}_f \circ (\mathcal{C}) \) is a presentable \( \infty \)-category.

In particular, if \( \mathcal{C} \) is a presentable \( \infty \)-category equipped with a symmetric monoidal structure, and the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves colimits separately in each variable, then \( \text{CAlg}(\mathcal{C}) \) is again presentable.

**Proof.** Assertion (1) follows from Lemma 3.2.3.4 and Proposition T.5.4.7.11. To prove (2), we combine (1) with Corollary 3.2.3.3.

We now turn to the proof of Proposition 3.2.3.1. We will need the following generalization of Proposition T.5.5.8.6:

**Lemma 3.2.3.6.** Let \( K \) be a sifted simplicial set, let \( \{ \mathcal{C}_i \}_{1 \leq i \leq n} \) be a finite collection of \( \infty \)-categories which admit \( K \)-indexed colimits, let \( \mathcal{D} \) be another \( \infty \)-category which admits \( K \)-indexed colimits, and let \( F : \prod_{1 \leq i \leq n} \mathcal{C}_i \to \mathcal{D} \) be a functor. Suppose that \( F \) preserves \( K \)-indexed colimits separately in each variable: that is, if we are given \( 1 \leq i \leq n \) and objects \( \{ C_j \in \mathcal{C}_j \}_{j \neq i} \), then the restriction of \( F \) to \( \{ C_j \} \times \cdots \times \{ C_{i-1} \} \times \mathcal{C}_i \times \{ C_{i+1} \} \times \cdots \times \{ C_n \} \) preserves \( K \)-indexed colimits. Then \( F \) preserves \( K \)-indexed colimits.

**Proof.** Choose \( S \subseteq \{ 1, \ldots, n \} \), and consider the following assertion:

\((*)_S\) Fix objects \( \{ C_i \in \mathcal{C}_i \}_{i \notin S} \). Then the restriction of \( F \) to \( \prod_{i \in S} \mathcal{C}_i \times \prod_{i \notin S} \{ C_i \} \) preserves \( K \)-indexed colimits.

We will prove \((*)_S\) using induction on the cardinality of \( S \). Taking \( S = \{ 1, \ldots, n \} \), we can deduce that \( F \) preserves \( K \)-indexed colimits and complete the proof.

If \( S \) is empty, then \((*)_S\) follows from Corollary T.4.4.4.10, since \( K \) is weakly contractible (Proposition T.5.5.8.7). If \( S \) contains a single element, then \((*)_S\) follows from the assumption that \( F \) preserves \( K \)-indexed colimits separately in each variable. We may therefore assume that \( S \) has at least two elements, so we can write \( S = S' \cup S'' \) where \( S' \) and \( S'' \) are disjoint nonempty subsets of \( S \). We now observe that \((*)_S\) follows from \((*)_{S'}\), \((*)_{S''}\)), and Proposition T.5.5.8.6.

**Lemma 3.2.3.7.** Let \( K \) be a sifted simplicial set, let \( \mathcal{O}^\otimes \) be an \( \infty \)-operad, and let \( p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a coCartesian fibration of \( \infty \)-operads which is compatible with \( K \)-indexed colimits (Definition 3.1.1.18). For each morphism \( f : X \to Y \) in \( \mathcal{O}^\otimes \), the associated functor \( f^*_Y : \mathcal{C}_X^\otimes \to \mathcal{C}_Y^\otimes \) preserves \( K \)-indexed colimits.

**Proof.** Factor \( f \) as a composition \( X \xrightarrow{f' j} Z \xrightarrow{f''} Y \), where \( f' \) is inert and \( f'' \) is active. Using Proposition 2.1.2.12, we deduce that \( \mathcal{C}_Z^\otimes \) is equivalent to a product \( \mathcal{C}_Z^\otimes \times \mathcal{C}_Z^\otimes \), and that \( f'_Y \) can be identified with the projection onto the first factor. Since \( \mathcal{C}_Z^\otimes \) and \( \mathcal{C}_Z^\otimes \) both admit \( K \)-indexed colimits, this projection preserves \( K \)-indexed colimits. We may therefore replace \( X \) by \( Z \) and thereby reduce to the case where \( f \) is active.

Let \( \langle n \rangle \) denote the image of \( Y \) in \( \mathcal{N}(\text{Fin}_*) \), and choose inert morphisms \( g_i : Y \to Y_i \) lying over \( \rho^i : \langle n \rangle \to \langle 1 \rangle \) for \( 1 \leq i \leq n \). Applying Proposition 2.1.2.12 again, we deduce that the functors \( (g_i) \) exhibit \( \mathcal{C}_Y^\otimes \) as equivalent to the product \( \prod_{1 \leq i \leq n} \mathcal{C}_{Y_i}^\otimes \). It will therefore suffice to show that each of the functors \( (g_i \circ f)_Y \) preserve \( K \)-indexed colimits. Replacing \( Y \) by \( Y_i \), we can reduce to the case \( n = 1 \).

Let \( \langle m \rangle \) denote the image of \( X \) in \( \mathcal{N}(\text{Fin}_*) \) and choose inert morphisms \( h_j : X \to X_j \) lying over \( \rho^j : \langle m \rangle \to \langle 1 \rangle \) for \( 1 \leq j \leq m \). Invoking Proposition 2.1.2.12 again, we obtain an equivalence \( \mathcal{C}_X^\otimes \simeq \prod_{1 \leq j \leq m} \mathcal{C}_{X_j}^\otimes \). It will therefore suffice to show that the composite map

\[
\phi : \prod_{1 \leq j \leq m} \mathcal{C}_{X_j}^\otimes \xrightarrow{F} \mathcal{C}_X^\otimes \xrightarrow{f^*_Y} \mathcal{C}_Y^\otimes
\]

preserves \( K \)-indexed colimits. Since \( p \) is compatible with \( K \)-indexed colimits, we conclude that \( \phi \) preserves \( K \)-indexed colimits separately in each variable. Since \( K \) is sifted, the desired result now follows from Lemma 3.2.3.6. \( \square \)
Proof of Proposition 3.2.3.1. Assertions (1), (2), and (3) follow immediately from Lemmas 3.2.3.7 and 3.2.2.9. The “only if” direction of (4) follows immediately from (2). To prove the converse, suppose that \( \overline{f} : K^\circ \rightarrow \mathrm{Alg}_{/O}(\mathcal{C}) \) has the property that \( \overline{f}_X \) is a colimit diagram in \( \mathcal{C}_X \) for each \( X \in \mathcal{O} \). We wish to prove that the analogous assertion holds for any \( X \in \mathcal{O}^{(n)} \). Choose inert morphisms \( g_{(i)} : X \rightarrow X_i \) lying over \( \rho^i : \langle n \rangle \rightarrow \langle 1 \rangle \) for \( 1 \leq i \leq n \). According to Proposition 2.1.2.12, the functors \( g_{(i)} \) induce an equivalence \( \mathcal{C}_{X_i}^\circ \simeq \prod_{1 \leq i \leq n} \mathcal{C}_{X_i} \). It will therefore suffice to prove that each composition \( g_{(i)} \circ \overline{f}_X \) is a colimit diagram \( K^\circ \rightarrow \mathcal{C}_{X_i} \). This follows from the observation that \( g_{(i)} \circ \overline{f}_X \simeq \overline{f}_{X_i} \). \( \square \)

For later use, we also record a variant of Proposition 3.2.3.1:

Proposition 3.2.3.8. Let \( K \) be a weakly contractible simplicial set and let \( p : \mathcal{C}^\circ \rightarrow \mathcal{O}^\circ \) be a coCartesian fibration of \( \infty \)-categories. Assume that the forgetful functor \( \mathcal{O}^\circ \rightarrow \mathrm{Comm}^\circ \) factors through the subcategory \( \mathcal{E}_0^\circ \subseteq \mathrm{Comm}^\circ \) of Example 2.1.1.19, that the \( \infty \)-category \( \mathcal{C}_X \) admits \( K \)-indexed colimits for each \( X \in \mathcal{O} \), and that each morphism \( \alpha : X \rightarrow Y \) in \( \mathcal{O} \) induces a functor \( \alpha^\circ : \mathcal{C}_X \rightarrow \mathcal{C}_Y \) which preserves \( K \)-indexed colimits. Then:

1. The \( \infty \)-category \( \mathrm{Fun}_{\mathcal{O}}(\mathcal{O}^\circ, \mathcal{C}^\circ) \) of sections of \( p \) admits \( K \)-indexed colimits.
2. A map \( \overline{f} : K^\circ \rightarrow \mathrm{Alg}_{/\mathcal{O}}(\mathcal{C}) \) is a colimit diagram if and only if, for each \( X \in \mathcal{O}^\circ \), the induced diagram \( \overline{f}_X : K^\circ \rightarrow \mathcal{C}_X^\circ \) is a colimit diagram.
3. The full subcategories \( \mathrm{Fun}_{\mathcal{O}}(\mathcal{O}^\circ, \mathcal{C}^\circ) \subseteq \mathrm{Alg}_{/\mathcal{O}}(\mathcal{C}) \subseteq \mathrm{Fun}_{\mathcal{O}}(\mathcal{O}^\circ, \mathcal{C}^\circ) \) are stable under \( K \)-indexed colimits.
4. A map \( \overline{f} : K^\circ \rightarrow \mathrm{Alg}_{/\mathcal{O}}(\mathcal{C}) \) is a colimit diagram if and only if, for each \( X \in \mathcal{O} \), the induced diagram \( \overline{f}_X : K^\circ \rightarrow \mathcal{C}_X \) is a colimit diagram.

Proof. Let \( \alpha : X \rightarrow Y \) be a morphism in \( \mathcal{O}^\circ \). Since the forgetful functor \( \mathcal{O}^\circ \rightarrow \mathrm{Comm}^\circ \) factors through \( \mathcal{E}_0^\circ \subseteq \mathrm{Comm}^\circ \), the induced map

\[
\alpha^\circ : \mathcal{C}_X \rightarrow \mathcal{C}_Y
\]

is equivalent to a product of maps \( \mathcal{C}_X \rightarrow \mathcal{C}_Y \) induced by morphisms \( X_i \rightarrow Y_i \) in \( \mathcal{O} \) and constant maps \( \Delta^0 \rightarrow \mathcal{C}_{Y_i} \). By assumption, each of these maps preserves \( K \)-indexed colimits (see Proposition T.4.4.2.9) so that \( \alpha^\circ \) preserves \( K \)-indexed colimits as well. Assertions (1), (2), and (3) now follow from Lemma 3.2.2.9, and assertion (4) follow as in the proof of Proposition 3.2.3.1. \( \square \)

3.2.4 Tensor Products of Commutative Algebras

The proof of the existence for colimits in \( \mathrm{Alg}_{/\mathcal{O}}(\mathcal{C}) \) given in Corollary 3.2.3.3 is rather indirect. In general, this seems to be necessary: there is no simple formula which describes the coproduct of a pair of associative algebras, for example. However, for commutative algebras we can be much more explicit: coproducts can be computed by forming the tensor product of the underlying algebras (see Proposition 3.2.4.7 below). To formulate this statement precisely, we first need to discuss tensor products of algebras over an \( \infty \)-operad.

Construction 3.2.4.1. Let \( f : \mathcal{O}^\circ \times \mathcal{O}^\circ \rightarrow \mathcal{O'}^\circ \) be a bifunctor of \( \infty \)-operads, and let \( q : \mathcal{O}^\circ \rightarrow \mathcal{O''}^\circ \) be a fibration of \( \infty \)-operads. We define a map of simplicial sets \( \mathrm{Alg}_{\mathcal{O}'/\mathcal{O''}}(\mathcal{C})^\circ \rightarrow \mathcal{O}^\circ \) by the following universal property: for every map of simplicial sets \( K \rightarrow \mathcal{O}^\circ \), there is a canonical bijection between \( \mathrm{Hom}_{(\mathrm{Set}_\Delta)_{/\mathcal{O}^\circ}}(K, \mathrm{Alg}_{\mathcal{O}'/\mathcal{O''}}(\mathcal{C})^\circ) \) and the set of commutative diagrams

\[
\begin{array}{ccc}
K \times \mathcal{O}^\circ & \xrightarrow{F} & \mathcal{C}^\circ \\
\downarrow & & \downarrow \\
\mathcal{O}^\circ \times \mathcal{O}^\circ & \rightarrow & \mathcal{O'}^\circ
\end{array}
\]
such that $F$ has the following property: for every vertex $v \in K$ and every inert morphism $\alpha$ in $\mathcal{O}^\otimes$, $F(\text{id}_v, \alpha)$ is an inert morphism in $\mathcal{E}^\otimes$.

**Remark 3.2.4.2.** Let $f : \mathcal{O}^\otimes \times \mathcal{O}^\otimes \to \mathcal{O}^\prime \otimes$ and $q : \mathcal{E}^\otimes \to \mathcal{O}^\prime \otimes$ be as in Construction 3.2.4.1. For every object $X \in \mathcal{O}^\otimes$, the restriction of $f$ to $\{X\} \times \mathcal{O}^\otimes$ determines a map of $\infty$-operads $\mathcal{O}^\otimes \to \mathcal{O}^\prime \otimes$, and we have a canonical isomorphism of the fiber $\text{Alg}_{\mathcal{O}^\prime / \mathcal{O}^\prime}(\mathcal{E})^\otimes_X \simeq \text{Alg}_{\mathcal{O}^\prime / \mathcal{O}^\prime}(\mathcal{E})^\otimes \times_{\mathcal{O}^\otimes} \{X\}$ with the $\infty$-category $\text{Alg}_{\mathcal{O}^\prime / \mathcal{O}^\prime}(\mathcal{E}) \subseteq \text{Fun}_{\mathcal{O}^\prime \otimes}(\mathcal{O}^\otimes, \mathcal{E}^\otimes)$.

The crucial properties of Construction 3.2.4.1 can be summarized as follows:

**Proposition 3.2.4.3.** Suppose we are given a bifunctor of $\infty$-operads $\mathcal{O}^\otimes \times \mathcal{O}^\otimes \to \mathcal{O}^\prime \otimes$ and a fibration of $\infty$-operads $q : \mathcal{E}^\otimes \to \mathcal{O}^\prime \otimes$. Then:

1. The map $p : \text{Alg}_{\mathcal{O}^\prime / \mathcal{O}^\prime}(\mathcal{E})^\otimes \to \mathcal{O}^\otimes$ is a fibration of $\infty$-operads.
2. A morphism $\alpha$ in $\text{Alg}_{\mathcal{O}^\prime / \mathcal{O}^\prime}(\mathcal{E})^\otimes$ is inert if and only if $p(\alpha)$ is an inert morphism in $\mathcal{O}^\prime$ and, for every object $X \in \mathcal{O}^\prime$, the image $\alpha(X)$ is an inert morphism in $\mathcal{E}^\otimes$.
3. Suppose that $q$ is a coCartesian fibration of $\infty$-operads. Then $p$ is a coCartesian fibration of $\infty$-operads.
4. Assume that $q$ is a coCartesian fibration of $\infty$-operads. Then a morphism $\alpha \in \text{Alg}_{\mathcal{O}^\prime / \mathcal{O}^\prime}(\mathcal{E})^\otimes$ is $p$-coCartesian if and only if, for every $X \in \mathcal{O}^\prime$, the image $\alpha(X)$ is a $q$-coCartesian morphism in $\mathcal{E}^\otimes$.

We will give the proof of Proposition 3.2.4.3 at the end of this section.

**Example 3.2.4.4.** Let $\mathcal{O}^\otimes$ be an arbitrary $\infty$-operad. Note that there is a unique bifunctor of $\infty$-operads $\text{Comm}^\otimes \times \mathcal{O}^\otimes \to \text{Comm}^\otimes$. In particular, for every $\infty$-operad $\mathcal{E}^\otimes$, Construction 3.2.4.1 produces a fibration of $\infty$-operads $\text{Alg}_{\mathcal{O} / \text{Comm}^\otimes}(\mathcal{E})^\otimes \to \text{Comm}^\otimes$. This is equivalent to specifying the underlying $\infty$-operad $\text{Alg}_{\mathcal{O} / \text{Comm}^\otimes}(\mathcal{E})^\otimes$, which we will denote by $\text{Alg}_{\mathcal{O} \otimes}(\mathcal{E})^\otimes$. The underlying $\infty$-category of this $\infty$-operad is the $\infty$-category $\text{Alg}_{\mathcal{O} \otimes}(\mathcal{E})$ of $\mathcal{O}^\otimes$-algebra objects of $\mathcal{E}$ (Remark 3.2.4.2).

Note that for every object $X \in \mathcal{O}$, we have an evaluation functor $e_X : \text{Alg}_{\mathcal{O} \otimes}(\mathcal{E})^\otimes \to \mathcal{E}^\otimes$. The description of inert morphisms in $\text{Alg}_{\mathcal{O} \otimes}(\mathcal{E})^\otimes$ provided by Proposition 3.2.4.3 shows that $e_X$ is a map of $\infty$-operads. If $\mathcal{E}^\otimes$ is a symmetric monoidal $\infty$-category, then Proposition 3.2.4.3 implies that $\text{Alg}_{\mathcal{O} \otimes}(\mathcal{E})^\otimes$ is also a symmetric monoidal $\infty$-category, and that the evaluation functors $e_X : \text{Alg}_{\mathcal{O} \otimes}(\mathcal{E})^\otimes \to \mathcal{E}^\otimes$ are symmetric monoidal functors. We can summarize the situation informally as follows: if $\mathcal{E}^\otimes$ is a symmetric monoidal $\infty$-category and $\mathcal{O}^\otimes$ is any $\infty$-operad, then the $\infty$-category $\text{Alg}_{\mathcal{O} \otimes}(\mathcal{E})$ inherits a symmetric monoidal structure, given by pointwise tensor product.

**Example 3.2.4.5.** The functor $\land : N(\text{Fin}_n) \times N(\text{Fin}_n) \to N(\text{Fin}_n)$ is a bifunctor of $\infty$-operads. Moreover, $\land$ induces a weak equivalence of $\infty$-preoperads $N(\text{Fin}_n)^\otimes \odot N(\text{Fin}_n)^\otimes \to N(\text{Fin}_n)^\otimes$. To prove this, it suffices to show that for any $\infty$-operad $\mathcal{E}$, the functor $\land$ induces an equivalence of $\infty$-categories $\text{CAlg}(\mathcal{E}) \to \text{CAlg}(\text{CAlg}(\mathcal{E}))$. This follows from Corollary 2.4.3.10, since the $\infty$-operad $\text{CAlg}(\mathcal{E})^\otimes$ is coCartesian (Proposition 3.2.4.10).

Let $\text{Op}_\infty$ denote the $\infty$-category of $\infty$-operads, and let $V : \text{Op}_\infty \to \text{Op}_\infty$ be induced by the left Quillen functor $\bullet \odot \text{Comm}^\otimes \otimes \mathcal{D}^\otimes$ from $\text{Op}_\infty$ to itself. It follows from Example 3.2.4.5 and Proposition T.5.2.7.4 that $V$ is a localization functor on $\text{Op}_\infty$. The following result characterizes the essential image of $V$:

**Proposition 3.2.4.6.** Let $\mathcal{E}^\otimes$ be an $\infty$-operad. The following conditions are equivalent:

1. The $\infty$-operad $\mathcal{E}^\otimes$ lies in the essential image of the localization functor $V$ defined above; in other words, there exists another $\infty$-operad $\mathcal{D}^\otimes$ and a bifunctor of $\infty$-operads $\theta : N(\text{Fin}_n)^\otimes \times \mathcal{D}^\otimes \to \mathcal{E}^\otimes$ which induces a weak equivalence of $\infty$-preoperads.
2. The $\infty$-operad $\mathcal{E}^\otimes$ is coCartesian.
Proof. Suppose first that (1) is satisfied. We will prove that $\mathcal{C}^\otimes$ is equivalent to $\mathcal{D}^\otimes$. Let $\theta_0 : N(\mathbb{F}n^*) \times \mathcal{D} \to \mathcal{C}^\otimes$ be the restriction of $\theta$. In view of Theorem 2.4.3.18, it will suffice to show that for every $\infty$-operad $\mathcal{E}^\otimes$, composition with $\theta_0$ induces an equivalence of $\infty$-categories $\text{Alg}_E(\mathcal{E}) \to \text{Fun}(\mathcal{D}, \text{Alg}_E(\mathcal{E}))$. This map factors as a composition

$$\text{Alg}_E(\mathcal{E}) \xrightarrow{\phi} \text{Alg}_D(\text{Alg}_E(\mathcal{E})) \xrightarrow{\phi'} \text{Fun}(\mathcal{D}, \text{Alg}_E(\mathcal{E})).$$

Our assumption that $\theta$ induces a weak equivalence of $\infty$-preoperads guarantees that $\phi$ is an equivalence of $\infty$-categories. To prove that $\phi'$ is a weak equivalence, it suffices to show that $\text{Alg}_E(\mathcal{E})^\otimes$ is a coCartesian $\infty$-operad (Proposition 2.4.3.9), which follows from Proposition 3.2.4.10.

Conversely, suppose that $\mathcal{C}^\otimes$ is coCartesian. We will prove that the canonical map $\mathcal{C}^\otimes \times \{1\} \to \mathcal{C}^\otimes \times N(\mathbb{F}n^*)$ induces a weak equivalence of $\infty$-preoperads $\mathcal{C}^\otimes \simeq \mathcal{C}^\otimes \times N(\mathbb{F}n^*)^\otimes$. Unwinding the definitions, it suffices to show that for every $\infty$-operad $\mathcal{D}^\otimes$, the canonical map

$$\text{Alg}_E(\text{Alg}_D(\mathcal{D})) \to \text{Alg}_D(\mathcal{D})$$

is an equivalence of $\infty$-categories. Invoking Theorem 2.4.3.18, we can reduce to proving that the forgetful functor $\psi : \text{Fun}(\mathcal{C}, \text{Alg}_D(\mathcal{D})) \to \text{Fun}(\mathcal{C}, \text{Alg}_D(\mathcal{D}))$ is an equivalence of $\infty$-categories. This is clear, since $\psi$ is a left inverse to the functor induced by the equivalence $\text{CAlg}(\mathcal{D}) \to \text{CAlg}(\text{Alg}_D(\mathcal{D}))$ of Example 3.2.4.5. \hfill $\square$

We are now ready to construct coproducts in an $\infty$-category $\text{CAlg}(\mathcal{C})$, where $\mathcal{C}^\otimes$ is any symmetric monoidal $\infty$-category.

**Proposition 3.2.4.7.** Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category. Then the symmetric monoidal structure on $\text{CAlg}(\mathcal{C})$ provided by Example 3.2.4.4 is coCartesian.

**Corollary 3.2.4.8.** Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category. Then the $\infty$-category $\text{CAlg}(\mathcal{C})$ admits finite coproducts.

**Proof of Proposition 3.2.4.7.** We will show that the symmetric monoidal structure on $\text{CAlg}(\mathcal{C})$ satisfies criterion (3) of Proposition 2.4.3.19. We first show that the unit object of $\text{CAlg}(\mathcal{C})$ is initial. It follows from Example 3.2.4.4 that the forgetful functor $\theta : \text{CAlg}(\mathcal{C}) \to \mathcal{C}$ can be promoted to a symmetric monoidal functor. According to Corollary 3.2.1.9, the $\infty$-category $\text{CAlg}(\mathcal{C})$ has an initial object $A_0$, which is characterized by the requirement that the unit map $1 \to A_0$ is an equivalence. Composing $A_0$ with the bifunctor of $\infty$-operads $\wedge : N(\mathbb{F}n^*) \times N(\mathbb{F}n^*) \to N(\mathbb{F}n^*)$ of Notation 2.2.5.1, we obtain trivial algebra $A_0^\otimes \in \text{CAlg}(\text{CAlg}(\mathcal{C}))$. In particular, the unit map $1_{\text{CAlg}(\mathcal{C})} \to A_0$ for $A_0^\otimes$ is an equivalence, which proves that the unit of $\text{CAlg}(\mathcal{C})$ is an initial object of $\text{CAlg}(\mathcal{C})$.

It remains to show that we can produce a collection of codiagonal map $\{\delta_A : A \otimes A \to A\}_{A \in \text{CAlg}(\mathcal{C})}$, satisfying the axioms (i), (ii), and (iii) of Proposition 2.4.3.19. For this, we observe that composition with the bifunctor $\wedge$ of Notation 2.2.5.1 induces a functor $l : \text{CAlg}(\mathcal{C}) \to \text{CAlg}(\text{CAlg}(\mathcal{C}))$. In particular, for every object $A \in \text{CAlg}(\mathcal{C})$, the multiplication on $l(A)$ induces a map $\delta_A : A \otimes A \to A$ in the $\infty$-category $\text{CAlg}(\mathcal{C})$. It is readily verified that these maps possess the desired properties. \hfill $\square$

**Remark 3.2.4.9.** Let $\mathcal{C}$ be an $\infty$-category which admits finite coproducts, and let $\mathcal{D}^\otimes$ be a symmetric monoidal $\infty$-category. According to Theorem 2.4.3.18, an $\infty$-operad map $F : \mathcal{C}^\otimes \to \mathcal{D}^\otimes$ is classified up to equivalence by the induced functor $f : \mathcal{C} \to \text{CAlg}(\mathcal{D})$. We note that $F$ is a symmetric monoidal functor if and only if for every finite collection of objects $C_i \in \mathcal{C}$, the induced map $\theta : \otimes f(C_i) \to f(\coprod C_i)$ is an equivalence in $\text{CAlg}(\mathcal{D})$. According to Proposition 3.2.4.7, we can identify the domain of $\theta$ with the coproduct of the commutative algebra objects $f(C_i)$. Consequently, we conclude that $F$ is symmetric monoidal if and only if $f$ preserves finite coproducts.

The following generalization of Proposition 3.2.4.7 is valid for an arbitrary $\infty$-operad $\mathcal{C}^\otimes$.

**Proposition 3.2.4.10.** Let $\mathcal{C}^\otimes$ be an $\infty$-operad. Then the $\infty$-operad $\text{CAlg}(\mathcal{C})^\otimes$ of Example 3.2.4.4 is coCartesian.
3.3. MODULES OVER $\infty$-OPERADS

Proof. Consider the functor $\text{CAlg}(\mathcal{E}) \to \text{CAlg}(\text{CAlg}(\mathcal{E}))$ appearing in the proof of Proposition 3.2.4.7. According to Theorem 2.4.3.18, this map determines an $\infty$-operad map $\theta : \text{CAlg}(\mathcal{E})^H \to \text{CAlg}(\mathcal{E})^\otimes$ which is well-defined up to homotopy. We wish to prove that $\theta$ is an equivalence. We first observe that $\theta$ induces an equivalence between the underlying $\infty$-categories, and is therefore essentially surjective. To prove that $\theta$ is fully faithful, choose a fully faithful map of $\infty$-categories $\theta^\prime : \mathcal{D}^\otimes \to \mathcal{D}^\otimes$ where $\mathcal{D}^\otimes$ is a symmetric monoidal $\infty$-category (Remark 2.2.4.10). We have a homotopy commutative diagram

\[
\begin{array}{ccc}
\text{CAlg}(\mathcal{E})^H & \xrightarrow{\theta} & \text{CAlg}(\mathcal{E})^\otimes \\
\downarrow & & \downarrow \\
\text{CAlg}(\mathcal{D})^H & \xrightarrow{\theta^\prime} & \text{CAlg}(\mathcal{D})^\otimes 
\end{array}
\]

where the vertical maps are fully faithful. Consequently, it will suffice to show that $\theta^\prime$ is an equivalence of symmetric monoidal $\infty$-categories. In view of Remark 2.1.3.8, it will suffice to show that $\theta^\prime$ is a symmetric monoidal functor. This is equivalent to the assertion that the composite functor $\text{CAlg}(\mathcal{D})^H \to \text{CAlg}(\mathcal{D})^\otimes \to \mathcal{D}^\otimes$ is symmetric monoidal (Proposition 3.2.4.3), which follows from Remark 3.2.4.9 because the underlying functor $\text{CAlg}(\mathcal{D}) \to \text{CAlg}(\mathcal{D})$ is equivalent to the identity (and therefore preserves finite coproducts).

We conclude this section with the proof of Proposition 3.2.4.3.

Proof of Proposition 3.2.4.3. We use the terminology of Appendix B.4. For every $\infty$-operad $\mathcal{O}^\otimes$, let $\Psi_\mathcal{O}$ denote the categorical pattern $(M, T, \{p_\alpha : A_0^\otimes \to \mathcal{O}^\otimes\}_{\alpha \in A})$ on $\mathcal{O}^\otimes$, where $M$ is the collection of inert morphisms in $\mathcal{O}^\otimes$, $T$ is the collection of all 2-simplices in $\mathcal{O}^\otimes$, and $A$ parametrizes all diagrams of inert morphisms $X_0 \leftarrow X \to X_1$ which lie over diagrams $\langle p \rangle \leftarrow \langle n \rangle \to \langle q \rangle$ in $\mathcal{F}_{\text{fin}}$, which induce a bijection $\langle p \rangle \coprod \langle q \rangle \to \langle n \rangle$.

If $f : \mathcal{O}^\otimes \times \mathcal{O}^\otimes \to \mathcal{O}^\otimes$ is a bifunctor of $\infty$-operads, then the construction $\overline{X} \mapsto \overline{X} \times \mathcal{O}^\otimes$ determines functor $F : (\text{Set}_\Delta^+)^{\otimes} / \mathcal{O} \to (\text{Set}_\Delta^+)^{\otimes} / \mathcal{O}^\otimes$, which admits a right adjoint $G : (\text{Set}_\Delta^\otimes / \mathcal{O} \otimes) \to (\text{Set}_\Delta^+)^{\otimes} / \mathcal{O}^\otimes$. Unwinding the definitions, we see that (1) and (2) are equivalent to the following assertion:

(*) The functor $G$ carries fibrant objects of $(\text{Set}_\Delta^+)^{\otimes} / \mathcal{O} \otimes$ to fibrant objects of $(\text{Set}_\Delta^+)^{\otimes} / \mathcal{O}^\otimes$.

To prove (*), it suffices to show that $G$ is a right Quillen functor or equivalently that $F$ is a left Quillen functor. We will prove a stronger assertion: the product map $(\text{Set}_\Delta^+)^{\otimes} / \mathcal{O} \otimes \times (\text{Set}_\Delta^+)^{\otimes} / \mathcal{O} \otimes \to (\text{Set}_\Delta^+)^{\otimes} / \mathcal{O} \otimes$ is a left Quillen bifunctor. This is a special case of Remark B.2.5.

The proofs of (3) and (4) are similar, after replacing the categorical pattern $\Psi_\mathcal{O}$ with $\Psi_\mathcal{O}^\prime = (M^\prime, T, \{p_\alpha : A_0^\otimes \to \mathcal{O}^\otimes\}_{\alpha \in A})$ where $M^\prime$ is the collection of all edges in $\mathcal{O}^\otimes$ (and similarly replacing $\Psi_\mathcal{O}^\otimes$ by $\Psi_\mathcal{O}^\otimes$).

3.3. Modules over $\infty$-Operads

Let $\mathcal{E}$ be a symmetric monoidal category, and suppose that $A$ is an algebra object of $\mathcal{E}$: that is, an object of $\mathcal{E}$ equipped with an associative (and unital) multiplication $m : A \otimes A \to A$. It then makes sense to consider left $A$-modules in $\mathcal{E}$: that is, objects $M \in \mathcal{E}$ equipped with a map $a : A \otimes M \to M$ such that the following diagrams commute

\[
\begin{array}{ccc}
A \otimes A \otimes M & \xrightarrow{m \otimes \text{id}_M} & A \otimes M \\
\downarrow \text{id}_A \otimes a & & \downarrow a \\
A \otimes M & \xrightarrow{a} & M
\end{array}
\]

\[
\begin{array}{ccc}
1 \otimes M & \xrightarrow{\text{id}_M} & A \otimes M \\
\downarrow a & & \downarrow a \\
M & \xrightarrow{a} & M
\end{array}
\]

There is also a corresponding theory of right $A$-modules in $\mathcal{E}$. If the multiplication on $A$ is commutative, then we can identify left modules with right modules and speak simply of $A$-modules in $\mathcal{E}$. Moreover, a
new phenomenon occurs: in many cases, the category $\text{Mod}_A(\mathcal{C})$ of $A$-modules in $\mathcal{C}$ inherits the structure of a symmetric monoidal category with respect to the relative tensor product over $A$: namely, we can define $M \otimes_A N$ to be the coequalizer of the diagram

$$M \otimes A \otimes N \longrightarrow M \otimes N$$

determined by the actions of $A$ on $M$ and $N$ (this construction is not always sensible: we must assume that the relevant coequalizers exist, and that they behave well with respect to the symmetric monoidal structure on $\mathcal{C}$).

If we do not assume that $A$ is commutative, then we can often still make sense of the relative tensor product $M \otimes_A N$ provided that $M$ is a right $A$-module and $N$ is a left $A$-module. However, this tensor product is merely an object of $\mathcal{C}$: it does not inherit any action of the algebra $A$. We can remedy this situation by assuming that $M$ and $N$ are bimodules for the algebra $A$: in this case, we can use the right module structure on $M$ and the left module structure on $N$ to define the tensor product $M \otimes_A N$, and this tensor product inherits the structure of a bimodule using the left module structure on $M$ and the right module structure on $N$. In good cases, this definition endows the category of $A$-bimodules in $\mathcal{C}$ with the structure of a monoidal category (which is not symmetric in general).

We can summarize the above discussion as follows: if $A$ is an object of $\mathcal{C}$ equipped with some algebraic structure (in this case, the structure of a commutative or associative algebra), then we can construct a new category of $A$-modules (in the associative case, we consider bimodules rather than left or right modules). This category is equipped with the same sort of algebraic structure as the original algebra $A$ (if $A$ is a commutative algebra, the category of $A$-modules inherits a tensor product which is commutative and associative up to isomorphism; in the case where $A$ is associative, the tensor product of bimodules $\otimes_A$ is merely associative up to isomorphism).

Our goal here is to describe an analogous picture for algebras of a more general nature: namely, $\mathcal{O}$-algebra objects of $\mathcal{C}$ for an arbitrary fibration of $\infty$-operads $\mathcal{O}^\otimes \to \mathcal{O}^\otimes$. We have seen that the collection of such algebras can itself be organized into an $\infty$-category $\text{Alg}_{/\mathcal{O}}(\mathcal{C})$. If $\mathcal{O}$ is unital, then we can associate to every object $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ a new $\infty$-category $\text{Mod}_A^\mathcal{O}(\mathcal{C})$, whose objects we will refer to as $A$-module objects of $\mathcal{C}$. We will lay out the general definitions in this section, and study important special cases (notably, the cases where $\mathcal{O}^\otimes$ is the commutative or associative $\infty$-operad) in §3.4.

There is very little we can say about the $\infty$-categories $\text{Mod}_A^\mathcal{O}(\mathcal{C})$ of module objects in the case where $\mathcal{O}^\otimes$ is a general unital $\infty$-operad. We have therefore adopted to work instead in the more restrictive setting of coherent $\infty$-operads. We will give the definition of coherence in §3.3.1 and give an alternate (more technical) characterization in §3.3.2. In §3.3.3, we will use show that if $\mathcal{O}$ is coherent, then every $\mathcal{O}$-algebra object $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ determines a fibration of $\infty$-operads $p : \text{Mod}_A^\mathcal{O}(\mathcal{C})^\otimes \to \mathcal{O}^\otimes$.

**Remark 3.3.0.1.** In good cases (which we will discuss in §3.4, one can show that $p$ is a coCartesian fibration of $\infty$-operads: in other words, the theory of $A$-modules inherits a tensor structure with exactly the same commutativity and associativity properties as the multiplication on $A$ itself (both are governed by the structure of the $\infty$-operad $\mathcal{O}^\otimes$). This picture was suggested by John Francis.

### 3.3.1 Coherent $\infty$-Operads

In this section, we introduce the notion of a coherent $\infty$-operad. Roughly speaking, the coherence of an $\infty$-operad $\mathcal{O}^\otimes$ is a condition which guarantees the existence of a reasonable theory of tensor products for modules over $\mathcal{O}$-algebras. Our goal here is to introduce the definition of coherence, provide a few key examples (see Examples 3.3.1.12, 3.3.1.13), and prove a somewhat technical result (Theorem 3.3.2.2) which will play an important role when we develop the theory of modules in §3.3.3.

We begin by sketching the basic idea. Let $\mathcal{O}^\otimes$ be a unital $\infty$-operad, and fix an active morphism $f : X \to Y$ in $\mathcal{O}^\otimes$. An extension of $f$ consists of an object $X_0 \in \mathcal{O}$ together with an active morphism $f^+ : X \oplus X_0 \to Y$ such that $f^+|_X \simeq f$; here the hypothesis that $\mathcal{O}^\otimes$ is unital guarantees that there is an essentially unique section to the projection $X \oplus X_0 \to X$, so that the restriction $f^+|_X$ is well-defined.
The collection of extensions of \( f \) can be organized into an \( \infty \)-category, which we will denote by \( \text{Ext}(f) \) (see Definition 3.3.1.4 below for a precise definition).

If \( g : Y \to Z \) is another active morphism, then there are canonical maps \( \text{Ext}(f) \to \text{Ext}(g \circ f) \leftarrow \text{Ext}(g) \), well-defined up to homotopy. In particular, we have canonical maps \( \text{Ext}(f) \leftarrow \text{Ext}(\text{id}_Y) \to \text{Ext}(g) \) which fit into a (homotopy coherent) diagram

\[
\begin{array}{ccc}
\text{Ext}(\text{id}_Y) & \to & \text{Ext}(f) \\
& & \downarrow \\
& & \text{Ext}(g) \\
& & \downarrow \\
& & \text{Ext}(g \circ f).
\end{array}
\]

If we assume that \( O \) is a Kan complex, then the \( \infty \)-categories appearing in this diagram are all Kan complexes. We will say that \( O \otimes \) is coherent if this diagram is a homotopy pushout square, for every pair of active morphisms \( f \) and \( g \) in \( O \otimes \).

We now make these ideas more precise. The first step is to give a careful definition of the \( \infty \)-category \( \text{Ext}(f) \).

**Definition 3.3.1.1.** We will say that a morphism \( \alpha : \langle m \rangle \to \langle n \rangle \) in \( \mathcal{N}(F_{\text{in}}^\ast) \) is semi-inert if \( \alpha^{-1}\{i\} \) has at most one element, for each \( i \in \langle n \rangle^\circ \). We will say that \( \alpha \) is null if \( \alpha \) carries \( \langle m \rangle \) to the base point of \( \langle n \rangle \).

Let \( p : O \otimes \to \mathcal{N}(F_{\text{in}}^\ast) \) be an \( \infty \)-operad, and let \( f : X \to Y \) be a morphism in \( O \otimes \). We will say that \( f \) is semi-inert if the following conditions are satisfied:

1. The image \( p(f) \) is a semi-inert morphism in \( \mathcal{N}(F_{\text{in}}^\ast) \).
2. For every inert morphism \( g : Y \to Z \) in \( O \otimes \), if \( p(g \circ f) \) is an inert morphism in \( \mathcal{N}(F_{\text{in}}^\ast) \), then \( g \circ f \) is an inert morphism in \( O \otimes \).

We will say that \( f \) is null if its image in \( \mathcal{N}(F_{\text{in}}^\ast) \) is null.

**Remark 3.3.1.2.** Let \( O \otimes \) be an \( \infty \)-operad. We can think of \( O \otimes \) as an \( \infty \)-category whose objects are finite sequences of objects \((X_1, \ldots, X_m)\) of \( O \). Let \( f : (X_1, \ldots, X_m) \to (Y_1, \ldots, Y_n) \) be a morphism in \( O \otimes \), corresponding to a map \( \alpha : \langle m \rangle \to \langle n \rangle \) and a collection of maps \( \phi_j \in \text{Mul}_O(\{X_i\}_{\alpha(i)=j}, Y_j) \).

Then \( f \) is semi-inert if and only for every \( j \in \langle n \rangle^\circ \), exactly one of the following conditions holds:

- \( a \) The set \( \alpha^{-1}\{j\} \) is empty.
- \( b \) The set \( \alpha^{-1}\{j\} \) contains exactly one element \( i \), and the map \( \phi_i \) is an equivalence between \( X_i \) and \( Y_j \) in the \( \infty \)-category \( O \).

The morphism \( f \) is inert if \( (b) \) holds for each \( j \in \langle n \rangle^\circ \), and null if \( (a) \) holds for each \( j \in \langle n \rangle^\circ \). It follows that every null morphism in \( O \otimes \) is semi-inert.

Note that if \( O \otimes \) is a unital \( \infty \)-operad, then the maps \( \phi_j \) are unique up to homotopy (in fact, up to a contractible space of choices) when \( \alpha^{-1}\{j\} \) is empty.

**Remark 3.3.1.3.** Let \( O \otimes \) be an \( \infty \)-operad, and suppose we are given a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{h} & Z \\
\downarrow{f} & & \downarrow{g} \\
Y & \xrightarrow{} &
\end{array}
\]
in $\mathcal{O}^\otimes$, where $f$ is inert. Then $g$ is semi-inert if and only if $h$ is semi-inert; this follows immediately from Remark 3.3.1.2.

**Definition 3.3.1.4.** Let $q : \mathcal{O}^\otimes \to N(\mathcal{F}\text{in}_*)$ be a unital $\infty$-operad, and let $\sigma : \Delta^n \to \mathcal{O}^\otimes_{\text{act}}$ be an $n$-simplex of $\mathcal{O}^\otimes$ corresponding to a composable chain $X_0 \xrightarrow{f_1} \ldots \xrightarrow{f_n} X_n$ of active morphisms in $\mathcal{O}^\otimes$.

If $S \subseteq [n]$ is a downward-closed subset, we let $\text{Ext}(\sigma, S)$ denote the full subcategory of $\text{Fun}(\Delta^n, \mathcal{O}^\otimes)_\sigma$ spanned by those diagrams

$$
\begin{array}{cccc}
X_0 & \xrightarrow{f_1} & \ldots & \xrightarrow{f_n} X_n \\
\downarrow g_0 & & \downarrow g_n \\
X'_0 & \xrightarrow{f'_1} & \ldots & \xrightarrow{f'_n} X'_n
\end{array}
$$

with the following properties:

(a) If $i \notin S$, the map $g_i$ is an equivalence.

(b) If $i \in S$, the map $g_i$ is semi-inert and $q(g_i)$ is an inclusion $\langle n_i \rangle \to \langle n_i + 1 \rangle$ which omits a single value $a_i \in \langle n_i + 1 \rangle$.

(c) If $0 < i \in S$, then the map $q(f'_i)$ carries $a_{i-1} \in q(X_{i-1}')$ to $a_i \in q(X_i')$.

(d) Each of the maps $f'_i$ is active.

If $f : \Delta^1 \to \mathcal{O}^\otimes_{\text{act}}$ is an active morphism in $\mathcal{O}^\otimes$, we will denote $\text{Ext}(f, \{0\})$ by $\text{Ext}(f)$.

**Remark 3.3.1.5.** Let $\text{Ext}(\sigma, S)$ be as in Definition 3.3.1.4. If $\mathcal{O}$ is a Kan complex, then it is easy to see that every morphism in $\text{Ext}(\sigma, S)$ is an equivalence, so that $\text{Ext}(\sigma, S)$ is also a Kan complex.

**Remark 3.3.1.6.** Let $\sigma : \Delta^n \to \mathcal{O}^\otimes_{\text{act}}$ correspond to a sequence of active morphisms

$$
X_0 \xrightarrow{f_1} X_1 \xrightarrow{f_2} \ldots \xrightarrow{f_n} X_n
$$

and let $S \subseteq [n]$. For every morphism $j : \Delta^m \to \Delta^n$, composition with $j$ induces a restriction map

$$
\text{Ext}(\sigma, S) \to \text{Ext}(\sigma \circ j, j^{-1}(S)).
$$

In particular, if $S$ has a largest element $i < n$, then we obtain a canonical map $\text{Ext}(\sigma, S) \to \text{Ext}(f_{i+1})$. If $\mathcal{O}$ is a Kan complex, then this map is a trivial Kan fibration.

**Remark 3.3.1.7.** Let $q : \mathcal{O}^\otimes \to N(\mathcal{F}\text{in}_*)$ be an $\infty$-operad, let $\sigma : \Delta^n \to \mathcal{O}^\otimes_{\text{act}}$ correspond to a sequence of active morphisms

$$
X_0 \xrightarrow{f_1} X_1 \xrightarrow{f_2} \ldots \xrightarrow{f_n} X_n,
$$

let $\langle m \rangle = q(X_n)$, and let $S$ be a downward-closed subset of $[n]$. Then $\text{Ext}(\sigma, S)$ decomposes naturally as a disjoint union $\coprod_{1 \leq i \leq m} \text{Ext}(\sigma, S)_i$, where $\text{Ext}(\sigma, S)_i$ denotes the full subcategory of $\text{Ext}(\sigma, S)$ spanned by those diagrams

$$
\begin{array}{cccc}
X_0 & \xrightarrow{f_1} & \ldots & \xrightarrow{f_n} X_n \\
\downarrow g_0 & & \downarrow g_n \\
X'_0 & \xrightarrow{f'_1} & \ldots & \xrightarrow{f'_n} X'_n
\end{array}
$$

where $q(f'_n \ldots f'_1)$ carries the unique element of $q(X'_0) - q(X_0)$ to $i \in \langle m \rangle \simeq q(X'_i)$. In this case, the diagram $\sigma$ is equivalent to an amalgamation $\bigoplus_{1 \leq i \leq m} \sigma_i$, and we have canonical equivalences $\text{Ext}(\sigma, S)_i \simeq \text{Ext}(\sigma_i, S)$. 

---

276 \textit{CHAPTER 3. ALGEBRAS AND MODULES OVER $\infty$-OPERADS}
Remark 3.3.1.8. Let \( f : \mathcal{O}^\otimes \to \mathcal{O}'^\otimes \) be a map of unital \( \infty \)-operads, where \( \mathcal{O} \) and \( \mathcal{O}' \) are Kan complexes. Let \( \sigma \) be an \( n \)-simplex of \( \mathcal{O}_{act}^\otimes \) and let \( S \) be a downward-closed subset of \([n]\). If \( f \) is an approximation to \( \mathcal{O}'^\otimes \) (see Definition 2.3.3.6), then it induces a homotopy equivalence \( \text{Ext}(\sigma, S) \to \text{Ext}(f(\sigma), S) \). This follows from Remark 3.3.1.6 and Corollary 2.3.3.17.

We are now ready to give the definition of a coherent \( \infty \)-operad.

Definition 3.3.1.9. Let \( \mathcal{O}^\otimes \) be an \( \infty \)-operad. We will say that \( \mathcal{O} \) is coherent if the following conditions are satisfied:

1. The \( \infty \)-operad \( \mathcal{O}^\otimes \) is unital.
2. The \( \infty \)-category \( \mathcal{O} \) is a Kan complex.
3. Suppose we are given a degenerate 3-simplex \( \sigma : \)

\[
\begin{array}{ccc}
Y & \xrightarrow{g} & Z \\
\downarrow^f & & \downarrow^f \\
X & \xleftarrow{\text{id}_Y} & Y
\end{array}
\]

in \( \mathcal{O}^\otimes \), where \( f \) and \( g \) are active. Then the diagram

\[
\begin{array}{ccc}
\text{Ext}(\sigma, \{0, 1\}) & \xrightarrow{\Delta^{(0,1,3)}} & \text{Ext}(\sigma, \{0, 1\}) \\
\downarrow & & \downarrow \\
\text{Ext}(\sigma, \{0, 2, 3\}) & \xrightarrow{\Delta^{(0,3)}} & \text{Ext}(\sigma, \{0\})
\end{array}
\]

is a homotopy pushout square.

Remark 3.3.1.10. Requirement (3) of Definition 3.3.1.9 can be stated more informally as follows: for every pair of active morphisms \( f : X \to Y \) and \( g : Y \to Z \), the (homotopy coherent) diagram of Kan complexes

\[
\begin{array}{ccc}
\text{Ext}(\text{id}_Y) & \xrightarrow{\text{Ext}(g)} & \text{Ext}(g) \\
\downarrow & & \downarrow \\
\text{Ext}(f) & \xrightarrow{\text{Ext}(gf)} & \text{Ext}(gf)
\end{array}
\]

is a homotopy pushout square.

Remark 3.3.1.11. In Definition 3.3.1.9, it is sufficient to require that condition (3) hold in cases where the object \( Z \) belongs to \( \mathcal{O} \): this is an immediate consequence of Remark 3.3.1.7.

Example 3.3.1.12. The commutative \( \infty \)-operad \( \text{Comm}^\otimes = \text{N}(\text{Fin}_*) \) is coherent. Unwinding the definitions, we note that for every active morphism \( f : \langle m \rangle \to \langle n \rangle \) in \( \text{N}(\text{Fin}_*) \), the Kan complex \( \text{Ext}(f) \) is canonically homotopy equivalent to \( \langle n \rangle^\circ = \{1, \ldots, n\} \), regarded as a discrete simplicial set. Since \( \text{Comm}^\otimes \) is unital and the underlying \( \infty \)-category \( \text{Comm} \simeq \Delta^0 \) is a Kan complex, we are reduced to proving that for every pair of active morphisms \( f : \langle l \rangle \to \langle m \rangle \) and \( g : \langle m \rangle \to \langle n \rangle \), the diagram

\[
\begin{array}{ccc}
\langle m \rangle^\circ & \xrightarrow{\langle n \rangle^\circ} & \langle n \rangle^\circ \\
\downarrow & & \downarrow \\
\langle m \rangle^\circ & \xrightarrow{\langle n \rangle^\circ} & \langle n \rangle^\circ
\end{array}
\]

is a homotopy pushout square, which is obvious.
**Example 3.3.1.13.** The $\infty$-operad $\mathbb{E}_0^\otimes$ is coherent. It is clear that $\mathbb{E}_0^\otimes$ is unital and that the underlying \(\infty\)-category $\mathbb{E}_0 \simeq \Delta^0$ is a Kan complex. It therefore suffices to prove that for every pair of active morphisms $f: \langle l \rangle \to \langle m \rangle$ and $g: \langle m \rangle \to \langle n \rangle$ in $\mathbb{E}_0^\otimes$, the induced diagram

$$
\begin{array}{c}
\text{Ext}(id_Y) \rightarrow \text{Ext}(g) \\
\downarrow \hspace{1cm} \downarrow \\
\text{Ext}(f) \rightarrow \text{Ext}(gf).
\end{array}
$$

is a homotopy pushout square. This follows from the observation that the above diagram can be identified with the commutative square of finite sets

$$
\begin{array}{c}
\emptyset \rightarrow \langle n \rangle - g(\langle m \rangle) \\
\downarrow \hspace{1cm} \downarrow \\
\langle m \rangle - f(\langle l \rangle) \rightarrow \langle n \rangle - gf(\langle l \rangle).
\end{array}
$$

**Remark 3.3.1.14.** We will later show that the little cubes operads $\mathbb{E}_k^\otimes$ are coherent for every integer $k$ (Theorem 5.1.1.11). This observation recovers Example 3.3.1.13 in the case $k = 0$ and Example 3.3.1.12 in the limiting case $k \to \infty$. We will give a more direct treatment of the case $k = 1$ when we discuss associative algebras in §4.1 (see Proposition 4.1.1.16).

**Proposition 3.3.1.15.** Let $f: \mathcal{O}^\otimes \to \mathcal{O}'^\otimes$ be a map between unital $\infty$-operads. Assume that both $\mathcal{O}$ and $\mathcal{O}'$ are Kan complexes and that $f$ is an approximation to $\mathcal{O}'^\otimes$ (see Definition 2.3.3.6). If $\mathcal{O}'^\otimes$ is coherent, then $\mathcal{O}^\otimes$ is coherent. The converse holds if the underlying map $\pi_0 \mathcal{O} \to \pi_0 \mathcal{O}'$ is surjective.

**Remark 3.3.1.16.** Let $\mathcal{O}^\otimes$ be a unital $\infty$-operad such that $\mathcal{O}$ is a Kan complex. According to Theorem 2.3.4.4, the $\infty$-operad $\mathcal{O}^\otimes$ can be obtained as the assembly of a $\mathcal{O}$-family of reduced unital $\infty$-operads $\mathcal{O}_X^\otimes \rightarrow \mathcal{O} \times \mathcal{N}(\text{Fin}_*)$. Proposition 3.3.1.15 (and Proposition 2.3.4.5) imply that $\mathcal{O}^\otimes$ is coherent if and only if, for each $X \in \mathcal{O}$, the $\infty$-operad $\mathcal{O}_X^\otimes$ is coherent. In §3.3.3, we will see that there is a good theory of modules associated to $\mathcal{O}$-algebras and to $\mathcal{O}_X$-algebras, for each $X \in \mathcal{O}$. One can show that these module theories are closely related to one another. To describe the relationship, suppose that $\mathcal{C}$ is another $\infty$-operad and $A \in \text{Alg}_{\mathcal{O}}(\mathcal{C})$ is a $\mathcal{O}$-algebra object of $\mathcal{C}$, corresponding to a family of $\mathcal{O}_X^\otimes$-algebra objects $\{A_X \in \text{Alg}_{\mathcal{O}_X^\otimes}(\mathcal{C})\}_{X \in \mathcal{O}}$. Then giving an $\mathcal{O}$-module object $M \in \text{Mod}_{\mathcal{O}}(\mathcal{C})$ is equivalent to giving a family $\{M_X \in \text{Mod}_{\mathcal{O}_X}(\mathcal{C})\}_{X \in \mathcal{O}'}$. We leave the precise formulation to the reader.

**Proof of Proposition 3.3.1.15.** We may assume without loss of generality that $f$ is a categorical fibration. The first assertion follows immediately Remark 3.3.1.8. To prove the second, it will suffice (by virtue of Remark 3.3.1.8) to show that every 3-simplex $\sigma: \Delta^3 \rightarrow \mathcal{O}_\mathcal{O}_{\text{act}}^\otimes$ can be lifted to a 3-simplex of $\mathcal{O}^\otimes_d$. Let $Z = \sigma(3) \in \mathcal{O}'$. Since $f$ is a categorical fibration, the induced map $\mathcal{O} \rightarrow \mathcal{O}'$ is a Kan fibration. Since this Kan fibration induces a surjection on connected components, it is surjective on vertices and we may write $Z = f(\bar{Z})$ for some $\bar{Z} \in \mathcal{O}$. Corollary 2.3.3.17 guarantees that the induced map $f': (\mathcal{O}_{/\bar{Z}}^\otimes)_{\text{act}} \rightarrow (\mathcal{O}_/Z^\otimes)_{\text{act}}$ is a categorical equivalence. Since $f$ is a categorical fibration, $f'$ is also a categorical fibration and therefore a trivial Kan fibration. We can interpret the 3-simplex $\sigma$ as a 2-simplex $\tau: \Delta^2 \rightarrow (\mathcal{O}_/Z^\otimes)_{\text{act}}$, which can be lifted to a 2-simplex $\tau': \Delta^2 \rightarrow (\mathcal{O}_{/\bar{Z}}^\otimes)_{\text{act}}$. This map determines a 3-simplex of $\mathcal{O}^\otimes_{\text{act}}$ lifting $\sigma$, as desired. \(\square\)

### 3.3.2 A Coherence Criterion

In §3.3.1, we introduced the notion of a **coherent** $\infty$-operad. In this section, we will characterize coherent $\infty$-operads as those $\infty$-operads which satisfy a certain technical condition (see Theorem 3.3.2.2). This condition will play an important role in the construction of $\infty$-categories of modules which we carry out in §3.3.3.
Notation 3.3.2.1. Let $\mathcal{O}^\otimes$ be a unital $\infty$-operad. We let $\mathcal{K}_\mathcal{O}$ denote the full subcategory of $\text{Fun}(\Delta^1, \mathcal{O}^\otimes)$ spanned by the semi-inert morphisms of $\mathcal{O}^\otimes$. For $i \in \{0, 1\}$ we let $e_i : \mathcal{K}_\mathcal{O} \to \mathcal{O}^\otimes$ be the map given by evaluation on $i$. We will say that a morphism in $\mathcal{K}_\mathcal{O}$ is inert if its images under $e_0$ and $e_1$ are inert morphisms in $\mathcal{O}^\otimes$.

We can now state our main result:

**Theorem 3.3.2.2.** Let $\mathcal{O}^\otimes$ be a unital $\infty$-operad such that $\mathcal{O}$ is a Kan complex. The following conditions are equivalent:

1. The $\infty$-operad $\mathcal{O}^\otimes$ is coherent.
2. The evaluation map $e_0 : \mathcal{K}_\mathcal{O} \to \mathcal{O}^\otimes$ is a flat categorical fibration (see Definition B.3.8).

The remainder of this section is devoted to the proof of Theorem 3.3.2.2. Our first step is to introduce an apparently weaker version of condition (2).

**Definition 3.3.2.3.** Let $q : \mathcal{O}^\otimes \to N(\text{Fin}_*)$ be a unital $\infty$-operad, and let $m \geq 0$ be an integer. We will say that a morphism $f : X \to X'$ in $\mathcal{O}^\otimes$ is $m$-semi-inert if $f$ is semi-inert and the underlying map $q(f) : \langle n \rangle \to \langle n' \rangle$ is such that the cardinality of the set $\langle n' \rangle - f(\langle n \rangle)$ is less than or equal to $m$.

By definition, an $\infty$-operad $\mathcal{O}^\otimes$ satisfies condition (2) of Theorem 3.3.2.2 if, for every map $\Delta^2 \to \mathcal{O}^\otimes$ corresponding to a diagram $X \to Y \to Z$ and every morphism $X \to Z$ in $\mathcal{K}_\mathcal{O}$ lifting the underlying map $X \to Z$, the $\infty$-category $(\mathcal{K}_\mathcal{O})_{/X/Z} \times_{\mathcal{O}^\otimes_{/X/Z}} \{Y\}$ is weakly contractible. We will say that $\mathcal{O}^\otimes$ is $m$-coherent if this condition holds whenever $X$ is an $m$-semi-inert morphism in $\mathcal{O}^\otimes$. We note that $\mathcal{K}_\mathcal{O} e_0 \to \mathcal{O}^\otimes$ is a flat categorical fibration if and only if $\mathcal{O}^\otimes$ is $m$-coherent for all $m \geq 0$.

**Lemma 3.3.2.4.** Let $\mathcal{O}^\otimes$ be a unital $\infty$-operad. The following conditions are equivalent:

1. The $\infty$-operad $\mathcal{O}^\otimes$ is $m$-coherent.
2. Consider a diagram $\sigma :$

$$
\begin{array}{ccc}
X & \longrightarrow & Y \\
| & & |
\downarrow f \\
X' & \longrightarrow &
\end{array}
$$

in $\mathcal{O}^\otimes$, where $f$ is $m$-semi-inert. Let $\mathcal{A}[\sigma]$ denote the full subcategory of $\mathcal{O}^\otimes_{/\sigma}$ spanned by those commutative diagrams

$$
\begin{array}{ccc}
X & \longrightarrow & Y \\
| & & |
\downarrow f \\
X' & \longrightarrow &
\end{array}
$$

where $g$ is semi-inert. Then the inclusion $\mathcal{A}[\sigma] \subseteq \mathcal{O}^\otimes_{/\sigma}$ is right cofinal.

3. Let $\sigma$ be as in (2), and let $Z'$ be an object of $\mathcal{O}^\otimes_{/\sigma}$, and let $\mathcal{A}[\sigma]_{/Z'}$ denote the full subcategory of $\mathcal{O}^\otimes_{/\sigma/Z'}$ spanned by those diagrams

$$
\begin{array}{ccc}
X & \longrightarrow & Y \\
| & & |
\downarrow f \\
X' & \longrightarrow &
\end{array}
$$

such that $g$ is semi-inert. Then $\mathcal{A}[\sigma]_{/Z'}$ is a weakly contractible simplicial set.
Proof. The equivalence of (2) and (3) follows immediately from Theorem T.4.1.3.1. We next prove that (1) \(\Rightarrow\) (3). We can extend \(\sigma\) and \(Z\) to a commutative diagram

\[
\begin{array}{ccc}
  X & \rightarrow & Y \\
  \downarrow f & & \downarrow h \\
  X' & \rightarrow & Z'
\end{array}
\]

where \(h\) is semi-inert (for example, we can take \(Z = Z'\) and \(h = \text{id}_{Z'}\)). The upper line of this diagram determines a diagram \(\Delta^2 \rightarrow \mathcal{O}^\otimes\). Let \(\mathcal{K}\) denote the fiber product \(\mathcal{K}_\Delta \times_{\mathcal{O}^\otimes} \Delta^2\). The maps \(f\) and \(h\) determine objects of \(\mathcal{K}_\Delta \times_{\mathcal{O}^\otimes} \Delta^2\), which we will denote by \(\mathcal{X}\) and \(\mathcal{Z}\). Since \(\mathcal{O}^\otimes\) is m-coherent, the \(\infty\)-category \(\mathcal{K}_{\Delta^2/\mathcal{O}}\times_{\mathcal{O}^\otimes} \Delta^2\{1\}\) is weakly contractible. We now observe that there is a trivial Kan fibration \(\psi : \mathcal{K}_{\Delta^2/\mathcal{O}} \rightarrow \mathcal{A}[\sigma]_{\mathcal{O}'},\) so that \(\mathcal{A}[\sigma]_{\mathcal{O}'}\) is likewise weakly contractible.

Now suppose that (3) is satisfied. We wish to prove that \(\mathcal{O}^\otimes\) is m-coherent. Fix a map \(\Delta^2 \rightarrow \mathcal{O}^\otimes\), and let \(\mathcal{K}\) be the fiber product \(\mathcal{K}_\Delta \times_{\mathcal{O}^\otimes} \Delta^2\). Suppose we are given objects \(\mathcal{X} \in \mathcal{K}_\Delta \times_{\mathcal{O}^\otimes} \Delta^2\{0\}\) and \(\mathcal{Z} \in \mathcal{K}_\Delta \times_{\mathcal{O}^\otimes} \Delta^2\{2\}\); we wish to prove that if \(\mathcal{X}\) is m-semi-inert, then \(\mathcal{K}_{\Delta^2/\mathcal{O}}\times_{\mathcal{O}^\otimes} \Delta^2\{1\}\) is weakly contractible. The above data determines a commutative diagram

\[
\begin{array}{ccc}
  X & \rightarrow & Y \\
  \downarrow f & & \downarrow h \\
  X' & \rightarrow & Z'
\end{array}
\]

in \(\mathcal{O}^\otimes\). If we let \(\sigma\) denote the left part of this diagram, then we can define a simplicial set \(\mathcal{A}[\sigma]_{\mathcal{O}'},\) as in (3), which is weakly contractible by assumption. Once again, we have a trivial Kan fibration \(\psi : \mathcal{K}_{\Delta^2/\mathcal{O}} \rightarrow \mathcal{A}[\sigma]_{\mathcal{O}'},\) so that \(\mathcal{K}_{\Delta^2/\mathcal{O}}\) is weakly contractible as desired. \(\Box\)

Remark 3.3.2.5. Let \(\mathcal{O}^\otimes, \sigma,\) and \(\mathcal{Z}'\) be as in the part (3) of Lemma 3.3.2.4. Let \(\mathcal{A}[\sigma]_{\mathcal{O}'}\) denote the full subcategory of \(\mathcal{A}[\sigma]_{\mathcal{O}}\) spanned by those diagrams

\[
\begin{array}{ccc}
  X & \rightarrow & Y \\
  \downarrow f & & \downarrow g \\
  X' & \rightarrow & Y'
\end{array}
\]

for which the map \(j\) is active. The inclusion \(\mathcal{A}[\sigma]_{\mathcal{O}'} \subseteq \mathcal{A}[\sigma]_{\mathcal{O}}\) admits a left adjoint, and is therefore a weak homotopy equivalence. Consequently, condition (3) of Lemma 3.3.2.4 is equivalent to the requirement that \(\mathcal{A}[\sigma]_{\mathcal{O}'}\) is weakly contractible.

Remark 3.3.2.6. In the situation of Lemma 3.3.2.4, let \(\mathcal{Z}' \in \mathcal{O}^\otimes\) and let \(\mathcal{B}\) denote the full subcategory of \(\mathcal{O}^\otimes_{\mathcal{Z}'},\) spanned by the active morphisms \(W \rightarrow \mathcal{Z}'\). The inclusion \(\mathcal{B} \subseteq \mathcal{O}^\otimes_{\mathcal{Z}'}\) admits a left adjoint \(L\). For any diagram \(\sigma:\)

\[
\begin{array}{c}
  X \\
  \downarrow \\
  X'
\end{array}
\]

in \(\mathcal{O}^\otimes_{\mathcal{Z}'},\) \(L\) induces a functor \(\mathcal{A}[\sigma]_{\mathcal{O}'} \rightarrow \mathcal{A}[\mathcal{L}\sigma]_{\mathcal{O}'},\) which restricts to an equivalence \(\mathcal{A}[\sigma]_{\mathcal{O}'} \rightarrow \mathcal{A}[\mathcal{L}\sigma]_{\mathcal{O}'},\) where \(\mathcal{A}[\sigma]_{\mathcal{O}'}\) and \(\mathcal{A}[\mathcal{L}\sigma]_{\mathcal{O}'}\) are defined as in Remark 3.3.2.5. Consequently, to verify condition (3) of Lemma 3.3.2.4, we are free to replace \(\sigma\) by \(\mathcal{L}\sigma\) and thereby reduce to the case where the maps \(X \rightarrow \mathcal{Z}',\) \(Y \rightarrow \mathcal{Z}'\), and \(X' \rightarrow \mathcal{Z}'\) are active.
Remark 3.3.2.7. Let \( Z' \in \mathcal{O}^\otimes \) be as in Lemma 3.3.2.4, and choose an equivalence \( Z' \simeq \bigoplus Z'_i \), where \( Z'_i \in \mathcal{O} \). Let \( \mathcal{B} \subseteq \mathcal{O}_{/Z'}^\otimes \) be defined as in Remark 3.3.2.6, and let \( \mathcal{B}_i \subseteq \mathcal{O}_{/Z'_i}^\otimes \) be defined similarly. Every diagram \( \sigma : \Lambda^n_0 \to \mathcal{B} \) can be identified with an amalgamation \( \bigoplus_i \sigma_i \) of diagrams \( \sigma_i : \Lambda^2_0 \to \mathcal{B}_i \). We observe that \( A[\sigma]_{/Z'} \) is equivalent to the product of the \( \infty \)-categories \( A[\sigma_i]_{/Z'_i} \). Consequently, to verify that \( A[\sigma_i]_{/Z'_i} \) is weakly contractible, we may replace \( Z' \) by \( Z'_i \) and thereby reduce to the case where \( Z' \in \mathcal{O} \).

Lemma 3.3.2.8. Let \( q : X \to S \) be an inner fibration of \( \infty \)-categories. Suppose that the following conditions are satisfied:

(a) The inner fibration \( q \) is flat.

(b) Each fiber \( X_s \) of \( q \) is weakly contractible.

(c) For every vertex \( x \in X \), the induced map \( X_x/ \to S_{q(x)/} \) has weakly contractible fibers.

Then for every map of simplicial sets \( S' \to S \), the pullback map \( X \times_S S' \to S' \) is weak homotopy equivalence.

In particular, \( q \) is a weak homotopy equivalence.

Proof. We will show more generally that for every map of simplicial sets \( S' \to S \), the induced map \( q_{S'} : X \times_S S' \to S' \) is a weak homotopy equivalence. Since the collection of weak homotopy equivalences is stable under filtered colimits, we may suppose that \( S' \) is finite. We now work by induction on the dimension \( n \) of \( S' \) and the number of simplices of \( S' \) of maximal dimension. If \( S' \) is empty the result is obvious; otherwise we have a homotopy pushout diagram

\[
\begin{array}{ccc}
\partial \Delta^n & \to & \Delta^n \\
\downarrow & & \downarrow \\
S'_0 & \to & S'.
\end{array}
\]

By the inductive hypothesis, the maps \( q_{S'_0} \) and \( q_{\partial \Delta^n} \) are weak homotopy equivalences. Since \( q_{S'} \) is a homotopy pushout of the morphisms \( q_{S'_0} \) with \( q_{\partial \Delta^n} \), we can reduce to proving that \( q_{\Delta^n} \) is a weak homotopy equivalence. Note that assumption (a) guarantees that \( q_{\Delta^n} \) is a flat categorical fibration. If \( n > 1 \), then we have a commutative diagram

\[
\begin{array}{ccc}
X \times_S \Lambda^n_1 & \to & X \times_S \Delta^n \\
\downarrow & & \downarrow \\
\Lambda^n_0 & \to & \Delta^n
\end{array}
\]

where the upper horizontal map is a categorical equivalence (Corollary B.3.15) and therefore a weak homotopy equivalence; the lower horizontal map is obviously a weak homotopy equivalence. Since \( q_{\Delta^n} \) is a weak homotopy equivalence by the inductive hypothesis, we conclude that \( q_{\Delta^n} \) is a weak homotopy equivalence.

It remains to treat the cases where \( n \leq 1 \). If \( n = 0 \), the desired result follows from (b). Suppose finally that \( n = 1 \). Let \( X' = X \times_S \Delta^1 \); we wish to prove that \( X' \) is weakly contractible. Let \( X'_0 \) and \( X'_1 \) denote the fibers of the map \( q_{\Delta^1} \), and let \( Y = \text{Fun}_{\Delta^1}(\Delta^1, X') \). According to Proposition B.3.17, the natural map

\[
X'_0 \coprod_{Y \times \{0\}} (Y \times \Delta^1) \coprod_{Y \times \{1\}} X'_1 \to X'
\]

is a categorical equivalence. Since \( X'_0 \) and \( X'_1 \) are weakly contractible, we are reduced to showing that \( Y \) is weakly contractible. Let \( p : Y \to X'_0 \) be the map given by evaluation at \( \{0\} \). Let \( x' \in X'_0 \), and let \( x \) denote its image in \( x \); the fiber \( p^{-1}\{x'\} \) is isomorphic to \( (X')^{x'}/ \times_{\Delta^1} \{1\} \) and therefore categorically equivalent to \( X_{x'/} \times_{\Delta^1} \{1\} \simeq X_{x/} \times_{S_{q(x)/}} \{f\} \), where \( f \) denotes the edge \( \Delta^1 \to S \) under consideration. Assumption (c) guarantees that \( p^{-1}\{x'\} \) is weakly contractible. Since \( p \) is a Cartesian fibration, Lemma T.4.1.3.2 guarantees that \( p \) is left cofinal and therefore a weak homotopy equivalence. Since \( X'_0 \) is weakly contractible by (b), we deduce that \( Y \) is weakly contractible as desired. \( \Box \)
Example 3.3.2.9. Let \( q : X \to S \) be a flat inner fibration of simplicial sets, and let \( f : x \to y \) be an edge of \( X \). Then the induced map \( X_{x/y} \to S_{q(x)/q(y)} \) satisfies the hypotheses of Lemma 3.3.2.8 (see Proposition B.3.13), and is therefore a weak homotopy equivalence.

Proposition 3.3.2.10. Let \( q : \mathcal{O}^\otimes \to N(\text{Fin}_*) \) be a unital \( \infty \)-operad. The following conditions are equivalent:

1. The evaluation map \( e_0 : \mathcal{K}_\mathcal{O} \to \mathcal{O}^\otimes \) is a flat categorical fibration.

2. Let \( Z \in \mathcal{O} \), and suppose we are given a diagram
   \[
   \begin{array}{ccc}
   X & \rightarrow & Y \\
   \downarrow f & & \downarrow g \\
   X' & \rightarrow & Y'
   \end{array}
   \]
   in \( \mathcal{O}^\otimes_{/Z} \) where \( f \) is semi-inert and the maps \( X \to Z \), \( Y \to Z \), and \( X' \to Z \) are active. Let \( \mathcal{B}[\sigma,Z] \) denote the full subcategory of \( \mathcal{O}^\otimes_{\sigma/\to Z} \) spanned by those diagrams
   \[
   \begin{array}{ccc}
   X & \rightarrow & Y \\
   \downarrow f & & \downarrow g \\
   X' & \rightarrow & Y'
   \end{array}
   \]
   in \( \mathcal{O}^\otimes \) where the map \( Y' \to Z \) is active, the map \( g \) is semi-inert, and the map \( q(X') \coprod_{q(X)} q(Y) \to q(Y') \) is a surjective map of pointed finite sets. Then \( \mathcal{B}[\sigma,Z] \) is weakly contractible.

3. Condition (2) holds in the special case where \( f \) is required to be 1-semi-inert.

Proof. In the situation of (2), let \( \mathcal{A}[\sigma]'_{/Z} \) be defined as in Remark 3.3.2.5. There is a canonical inclusion \( \mathcal{B}[\sigma,Z] \subseteq \mathcal{A}[\sigma]'_{/Z} \). Our assumption that \( \mathcal{O}^\otimes \) is unital implies that this inclusion admits a right adjoint, and is therefore a weak homotopy equivalence. The equivalence (1) \( \iff \) (2) now follows by combining Lemma 3.3.2.4 with Remarks 3.3.2.5, 3.3.2.6, and 3.3.2.7. The same argument shows that (3) is equivalent to the condition that \( \mathcal{O}^\otimes \) is 1-coherent. The implication (2) \( \Rightarrow \) (3) is obvious; we will complete the proof by showing that (3) \( \Rightarrow \) (2).

Let \( (\sigma,Z) \) be as in (2); we wish to show that \( \mathcal{B}[\sigma,Z] \) is weakly contractible. The image \( q(f) \) is a semi-inert morphism \( \langle n \rangle \leftrightarrow \langle n+m \rangle \) in \( N(\text{Fin}_*) \), for some \( m \geq 0 \). If \( m = 0 \), then \( \mathcal{B}[\sigma,Z] \) has an initial object and there is nothing to prove. We assume therefore that \( m > 0 \), so that (since \( \mathcal{O}^\otimes \) is unital) \( f \) admits a factorization

\[
X \xrightarrow{f'} X_0 \xrightarrow{f''} X'
\]

such that \( q(f') \) is an inclusion \( \langle n \rangle \leftrightarrow \langle n+1 \rangle \) and \( q(f'') \) is an inclusion \( \langle n+1 \rangle \leftrightarrow \langle n+m \rangle \). Let \( \tau : \Delta^1 \coprod_{\{0\}} \Delta^2 \to \mathcal{O}^\otimes_{/Z} \) be the diagram given by \( Y \leftarrow X \xrightarrow{X} X_0 \to X' \), and let \( \tau_0 \) be the restriction of \( \tau \) to \( \Delta^1 \coprod_{\{0\}} \Delta^1 \). Let \( \mathcal{C} \) denote the \( \infty \)-category

\[
\text{Fun}(\Delta^1, \mathcal{O}^\otimes_{\tau_0/\to Z} \times_{\mathcal{O}^\otimes_{/Z}} \mathcal{O}^\otimes_{/Z})
\]

whose objects are commutative diagrams

\[
\begin{array}{ccc}
X & \rightarrow & Y \\
\downarrow f' & & \downarrow g' \\
X_0 & \rightarrow & Y_0 \\
\downarrow f'' & & \downarrow g'' \\
X' & \rightarrow & Y' \rightarrow Z
\end{array}
\]
3.3. MODULES OVER ∞-OPERADS

in $O^\otimes$. Let $C_0$ denote the full subcategory of $C$ spanned by those diagrams where the maps $g'$ and $g''$ are semi-inert, the maps $Y_0 \to Z$ and $Y' \to Z$ are active, and the maps $q(Y) \coprod_{q(Y_0)} q(X_0) \to q(Y_0)$ and $q(Y_0) \coprod_{q(Y_0)} q(X') \to q(Y')$ are surjective. There are evident forgetful functors $B[\sigma], Z \xleftarrow{\psi} C_0 \xrightarrow{\psi} B[\tau_0, Z]$. The map $\varphi$ admits a right adjoint and is therefore a weak homotopy equivalence. The simplicial set $B[\tau_0, Z]$, and therefore weakly contractible by the inductive hypothesis. To complete the proof, it will suffice to show that $\psi$ is a weak homotopy equivalence. For this, we will show that $\psi$ satisfies the hypotheses of Lemma 3.3.2.8:

(a) The map $\psi$ is a flat inner fibration. Fix a diagram

\begin{equation*}
\begin{array}{ccc}
B & \to & C \\
\downarrow & & \downarrow \\
A & \xrightarrow{j} & C
\end{array}
\end{equation*}

in $A[\tau_0]_Z$ and a morphism $\overline{j} : \overline{A} \to \overline{C}$ in $C_0$ lifting $j$; we wish to show that the $\infty$-category

$Z = (C_0)_{/A} \times_{(B[\tau_0, Z])_A} \{B\}$

is weakly contractible. We have a commutative diagram

\begin{equation*}
\begin{array}{cccc}
X & \to & Y & \to & Y_B \\
\downarrow & & \downarrow & & \downarrow \\
X_0 & \to & Y_A & \to & Y_B & \to & Y_C \\
\downarrow & & \downarrow & & \downarrow \\
X' & \to & Y'_A & \to & Y'_B & \to & Y'_C & \to & Z
\end{array}
\end{equation*}

in $O^\otimes$. Restricting our attention to the rectangle in the lower right, we obtain a commutative diagram

\begin{equation*}
\begin{array}{ccc}
Y_B & \to & Y_C \\
\downarrow & & \downarrow \\
Y_A & \xrightarrow{j_0} & Y_C
\end{array}
\end{equation*}

in $O^\otimes$ and a morphism $\overline{j}_0 : \overline{Y}_A \to \overline{Y}_C$ in $K_0$ lifting $j$. Let $Z_0 = (K_0)_{/A} \times_{O^\otimes} \{Y_B\}$ be the $\infty$-category whose objects are diagrams

\begin{equation*}
\begin{array}{ccc}
Y_A & \to & Y_B & \to & Y_C \\
\downarrow & & \downarrow & & \downarrow \\
Y'_A & \to & Y'_B & \to & Y'_C
\end{array}
\end{equation*}

in $O^\otimes$. Let $Z_1$ be the full subcategory of $Z_0$ spanned by those diagrams for which the map $Y'_B \to Y'_C$ is active, and let $Z_2$ be the full subcategory of $Z_1$ spanned by those maps for which $q(Y_B) \coprod_{q(Y_A)} q(Y'_B) \to q(Y_B)$ is surjective. Since the map $q(Y_A) \coprod_{q(Y_0)} q(X') \to q(Y'_B)$ is surjective and $f''$ is 1-semi-inert, we deduce that $\alpha$ is 1-semi-inert. Condition (3) guarantees that $O^\otimes$ is 1-coherent, so the $\infty$-category $Z_0$ is weakly contractible. The inclusion $Z_1 \subseteq Z_0$ admits a left adjoint, and the inclusion $Z_2 \subseteq Z_1$ admits a right adjoint. It follows that both of these inclusions are weak homotopy equivalences, so that $Z_2$ is weakly contractible. There is an evident restriction map $Z \to Z_2$, which is easily shown to be a trivial Kan fibration. It follows that $Z$ is weakly contractible as desired.
(b) The fibers of $\psi$ are weakly contractible. To prove this, we observe an object $b \in \mathcal{B}[\tau_0, Z]$ determines a commutative diagram

$$
\begin{array}{ccc}
X & \longrightarrow & Y \\
\downarrow & & \downarrow \\
X_0 & \longrightarrow & Y_0
\end{array}
$$

in $\mathcal{O}^\otimes_{/Z}$. If we let $\sigma'$ denote the lower part of this diagram, then we have a trivial Kan fibration $\psi^{-1}(b) \to \mathcal{B}[\tau_0, Z]$, which is weakly contractible by virtue of (3).

(c) For every object $c \in \mathcal{C}_0$ and every morphism $\beta : \psi(c) \to b$ in $\mathcal{B}[\tau_0, Z]$, the $\infty$-category $Y = (\mathcal{C}_0)_c \times_{\mathcal{B}[\tau_0, Z]} \psi(c)/\{\beta\}$ is weakly contractible. The pair $(c, \beta)$ determines a diagram

$$
\begin{array}{ccc}
X & \longrightarrow & Y \\
\downarrow & & \downarrow \\
X_0 & \longrightarrow & Y_0 & \longrightarrow & Y_1 \\
\downarrow & & \downarrow & \downarrow & \downarrow \\
X' & \longrightarrow & Y'
\end{array}
$$

in $\mathcal{O}^\otimes_{/Z}$. Let $\sigma''$ denote the lower right corner of this diagram. Then we have a trivial Kan fibration $Y \to \mathcal{B}[\sigma'', Z]$. Since the map $q(Y_0) \coprod_{q(X_0)} q(X') \to q(Y')$ is surjective, we deduce that $g''$ is 1-semi-inert, so that $\mathcal{B}[\sigma'', Z]$ is weakly contractible by virtue of (3).

Proof of Theorem 3.3.2.2. In view of Proposition 3.3.2.10, we can rephrase Theorem 3.3.2.2 as follows: if $\mathcal{O}^\otimes$ is a unital $\infty$-operad and $\mathcal{O}$ is a Kan complex, then $\mathcal{O}^\otimes$ is coherent if and only if it is 1-coherent.

Fix a pair of active morphisms $f : X \to Y$ and $g : Y \to Z$ in $\mathcal{O}^\otimes$, where $Z \in \mathcal{O}$. Let $\sigma : \Delta^3 \to \mathcal{O}^\otimes$ be as in the formulation of condition (3), and consider the diagram

$$
\begin{array}{ccc}
\text{Ext}(\sigma, \{0, 1\}) & \longrightarrow & \text{Ext}(\sigma|\Delta^{(0,1,3)}, \{0, 1\}) \\
\downarrow & & \downarrow \\
\text{Ext}(\sigma|\Delta^{(0,2,3)}, \{0\}) & \longrightarrow & \text{Ext}(\sigma|\Delta^{(0,3)}, \{0\}).
\end{array}
$$

Each of the maps in this diagram is a Kan fibration between Kan complexes. Consequently, $\mathcal{O}^\otimes$ is 1-coherent if and only if, for each vertex $v$ of $\text{Ext}(\sigma|\Delta^{(0,3)}, \{0\})$, the induced diagram of fibers

$$
\text{Ext}(\sigma|\Delta^{(0,1,3)}, \{0, 1\})_v \leftarrow \text{Ext}(\sigma, \{0, 1\})_v \to \text{Ext}(\sigma|\Delta^{(0,2,3)}, \{0\})_v
$$

has a contractible homotopy pushout. Without loss of generality, we may assume that $v$ determines a diagram

$$
\begin{array}{ccc}
X & \longrightarrow & Y \\
\downarrow & & \downarrow \\
X' & \longrightarrow & Z
\end{array}
$$
in $\mathcal{O}^{\otimes}$, where the left vertical map is 1-semi-inert. Let $\tau$ denote the induced diagram $X' \leftarrow X \to Y$ in $\mathcal{O}^{\otimes}/Z$, and let $\mathcal{B}[\tau, Z]$ be the $\infty$-category defined in Proposition 3.3.2.10. Let $\mathcal{B}[\tau, Z]_1$ denote the full subcategory of $\mathcal{B}[\tau, Z]$ spanned by those objects which correspond to diagrams

\[
\begin{array}{ccc}
X & \longrightarrow & Y \\
\downarrow & & \downarrow \\
X' & \longrightarrow & Y'
\end{array}
\]

where the right vertical map is an equivalence. Then there is a unique map $p : \mathcal{B}[\tau, Z] \to \Delta^1$ such that $p^{-1}\{1\} \simeq \mathcal{B}[\tau, Z]_1$. Let $\mathcal{B}[\tau, Z]_0 = p^{-1}\{0\}$, and let $\mathcal{Z} = \text{Fun}_{\Delta^1}(\Delta^1, \mathcal{B}[\tau, Z])$ be the $\infty$-category of sections of $p$. We have a commutative diagram

\[
\begin{array}{ccc}
\text{Ext}(\sigma|\Delta^{(0,1,3)}, \{0, 1\})_v & \longrightarrow & \text{Ext}(\sigma, \{0, 1\})_v \\
\downarrow & & \downarrow \\
\mathcal{B}[\tau, Z]_0 & \leftarrow & \mathcal{Z} & \rightarrow & \mathcal{B}[\tau, Z]_1.
\end{array}
\]

in which the vertical maps are trivial Kan fibrations. Consequently, condition $\mathcal{O}^{\otimes}$ is 1-coherent if and only if each homotopy pushout

\[
\mathcal{B}[\tau, Z]_0 \coprod_{\mathcal{Z}} (\mathcal{Z} \times \Delta^1) \coprod_{\mathcal{Z} \times \{1\}} \mathcal{B}[\tau, Z]_1
\]

is weakly contractible. According to Proposition B.3.17, this homotopy pushout is categorically equivalent to $\mathcal{B}[\tau, Z]$, so that the 1-coherence of $\mathcal{O}^{\otimes}$ is equivalent to the coherence of $\mathcal{O}^{\otimes}$.

### 3.3.3 Module Objects

Let $\mathcal{O}^{\otimes}$ be a coherent $\infty$-operad and suppose we are given a fibration of $\infty$-operads $\mathcal{C}^{\otimes} \to \mathcal{O}^{\otimes}$. In this section, we will explain how to associate to each algebra object $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ a new $\infty$-operad $\text{Mod}_A^{\otimes}(\mathcal{C})^{\otimes}$ of $A$-modules in $\mathcal{C}$. The construction of $\text{Mod}_A^{\otimes}(\mathcal{C})^{\otimes}$ (as a simplicial set with a map to $N(\text{Fin}_*)$) is fairly straightforward; the bulk of our work will be in proving that $\text{Mod}_A^{\otimes}(\mathcal{C})^{\otimes}$ is actually an $\infty$-operad (Theorem 3.3.3.9).

**Construction 3.3.3.1.** Let $\mathcal{O}^{\otimes}$ be a unital $\infty$-operad and let $\mathcal{C}^{\otimes} \to \mathcal{O}^{\otimes}$ be a map of generalized $\infty$-operads. We let $\mathcal{K}_0 \subseteq \text{Fun}(\Delta^1, \mathcal{O}^{\otimes})$ denote the full subcategory spanned by the semi-inert morphisms in $\mathcal{O}^{\otimes}$ (Notation 3.3.2.1), and $e_i : \mathcal{K}_0 \to \mathcal{O}^{\otimes}$ the evaluation functor for $i \in \{0, 1\}$. We define a simplicial set $\overline{\text{Mod}}^{\otimes}(\mathcal{C})^{\otimes}$ equipped with a map $q : \overline{\text{Mod}}^{\otimes}(\mathcal{C})^{\otimes} \to \mathcal{O}^{\otimes}$ so that the following universal property is satisfied: for every map of simplicial sets $X \to \mathcal{O}^{\otimes}$, there is a canonical bijection

\[
\text{Fun}_{\mathcal{O}^{\otimes}}(X, \overline{\text{Mod}}^{\otimes}(\mathcal{C})^{\otimes}) \simeq \text{Fun}_{\text{Fun}(\{1\}, \mathcal{O}^{\otimes})}(X \times_{\text{Fun}(\{0\}, \mathcal{O}^{\otimes})} \mathcal{K}_0, \mathcal{C}^{\otimes}).
\]

We let $\overline{\text{Mod}}^{\otimes}(\mathcal{C})^{\otimes}$ denote the full simplicial subset of $\overline{\text{Mod}}^{\otimes}(\mathcal{C})^{\otimes}$ spanned by those vertices $\sigma$ with the following property: if we let $v = q(\sigma) \in \mathcal{O}^{\otimes}$, then $\sigma$ determines a functor

\[
\{v\} \times_{\mathcal{O}^{\otimes}} \mathcal{K}_0 \to \mathcal{C}^{\otimes}
\]

which carries inert morphisms to inert morphisms (recall that a morphism $\alpha$ in $\mathcal{K}_0$ is inert if its images $e_0(\alpha)$ and $e_1(\alpha)$ are inert).

**Notation 3.3.3.2.** Let $\mathcal{O}^{\otimes}$ be an $\infty$-operad. We let $\mathcal{K}_0^{\otimes}$ denote the full subcategory of $\mathcal{K}_0$ spanned by the null morphisms $f : X \to Y$ in $\mathcal{O}^{\otimes}$. For $i = 0, 1$, we let $e_i^{\otimes}$ denote the restriction to $\mathcal{K}_0^{\otimes}$ of the evaluation map $e_i : \mathcal{K}_0 \to \mathcal{O}^{\otimes}$.
Lemma 3.3.3.3. Let $\mathcal{O}^\otimes$ be a unital $\infty$-operad. Then the maps $e_0^0$ and $e_1^0$ determine a trivial Kan fibration $\theta : \mathcal{K}_0^0 \to \mathcal{O}^\otimes \times \mathcal{O}^\otimes$.

Proof. Since $\theta$ is evidently a categorical fibration, it will suffice to show that $\theta$ is a categorical equivalence. Corollary T.2.4.7.12 implies that evaluation at $\{0\}$ induces a Cartesian fibration $p : \text{Fun}(\Delta^1, \mathcal{O}^\otimes) \to \mathcal{O}^\otimes$. If $f$ is a null morphism in $\mathcal{O}^\otimes$, then so is $f \circ g$ for every morphism $g$ in $\mathcal{O}^\otimes$; it follows that if $\alpha : f \to f'$ is a $p$-Cartesian morphism in $\text{Fun}(\Delta^1, \mathcal{O}^\otimes)$ and $f' \in \mathcal{K}_0^0$, then $f \in \mathcal{K}_0^0$. Consequently, $p$ restricts to a Cartesian fibration $e_0^0 : \mathcal{K}_0^0 \to \mathcal{O}^\otimes$. Moreover, a morphism $\alpha$ in $\mathcal{K}_0^0$ is $e_0^0$-Cartesian if and only if $e_1^0(\alpha)$ is an equivalence. Consequently, $\theta$ fits into a commutative diagram

and carries $e_0^0$-Cartesian morphisms to $\pi$-Cartesian morphisms. According to Corollary T.2.4.4.4, it will suffice to show that for every object $X \in \mathcal{O}^\otimes$, the map $\theta$ induces a categorical equivalence $\theta_X : (\mathcal{O}^\otimes)_X^0 \to \mathcal{O}^\otimes$, where $(\mathcal{O}^\otimes)_X^0$ is the full subcategory of $(\mathcal{O}^\otimes)_X^0$ spanned by the null morphisms $X \to Y$.

The map $\theta_X$ is obtained by restricting the left fibration $q : (\mathcal{O}^\otimes)_X^0 \to \mathcal{O}^\otimes$. We observe that if $f$ is a null morphism in $\mathcal{O}^\otimes$, then so is every composition of the form $g \circ f$. It follows that if $\alpha : f \to f'$ is a morphism in $(\mathcal{O}^\otimes)_X^0$ such that $f \in (\mathcal{O}^\otimes)_X^0$, then $f' \in (\mathcal{O}^\otimes)_X^0$, so the map $q$ restricts to a left fibration $\theta_X : (\mathcal{O}^\otimes)_X^0 \to \mathcal{O}^\otimes$. Since the fibers of $\theta_X$ are contractible (Lemma 3.3.3.11), Lemma T.2.1.3.4 implies that $\theta_X$ is a trivial Kan fibration.

\[ \square \]

Corollary 3.3.3.4. Let $\mathcal{O}^\otimes$ be a unital $\infty$-operad. The projection map $e_0^0 : \mathcal{K}_0^0 \to \mathcal{O}^\otimes$ is a flat categorical fibration.

Notation 3.3.3.5. Let $\mathcal{O}^\otimes$ be an $\infty$-operad and let $\mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a $\mathcal{O}$-operad family. We define a simplicial set $\text{Alg}_\mathcal{O}(\mathcal{C})$ equipped with a map $\text{Alg}_\mathcal{O}(\mathcal{C}) \to \mathcal{O}^\otimes$ so that the following universal property is satisfied: for every simplicial set $X$ with a map $X \to \mathcal{O}^\otimes$, we have a canonical bijection

\[ \text{Fun}_{\mathcal{O}^\otimes}(X, \text{Alg}_\mathcal{O}(\mathcal{C})) \simeq \text{Fun}_{\mathcal{O}^\otimes}(X \times_{\mathcal{O}^\otimes} \mathcal{K}_0^0, \mathcal{O}^\otimes, \mathcal{C}^\otimes). \]

We observe that for every object $Y \in \mathcal{O}^\otimes$, a vertex of the fiber of $\text{Alg}_\mathcal{O}(\mathcal{C}) \times_{\mathcal{O}^\otimes} \{Y\}$ can be identified with a functor $F : \{Y\} \times_{\mathcal{O}^\otimes} \mathcal{K}_0^0 \to \mathcal{C}^\otimes$. We let $p_{\text{Alg}_\mathcal{O}(\mathcal{C})}$ denote the full simplicial subset of $\text{Alg}_\mathcal{O}(\mathcal{C})$ spanned by those vertices for which the functor $F$ preserves inert morphisms.

Remark 3.3.3.6. Let $\mathcal{O}^\otimes$ be a unital $\infty$-operad and $\mathcal{C}^\otimes \to \mathcal{O}^\otimes$ a $\mathcal{O}$-operad family. The map $\theta : \mathcal{K}_0^0 \to \mathcal{O}^\otimes \times \mathcal{O}^\otimes$ of Lemma 3.3.3.3 induces a map $\phi : \mathcal{O}^\otimes \times \text{Fun}_{\mathcal{O}^\otimes}(\mathcal{O}^\otimes, \mathcal{C}^\otimes) \to \text{Alg}_\mathcal{O}(\mathcal{C})$. Unwinding the definitions, we see that $\phi^{-1}p_{\text{Alg}_\mathcal{O}(\mathcal{C})}$ can be identified with the product $\mathcal{O}^\otimes \times \text{Alg}_\mathcal{O}(\mathcal{C})$.

Remark 3.3.3.7. Let $\mathcal{O}^\otimes$ be a unital $\infty$-operad. Since the map $e_1^0 : \mathcal{K}_0^0 \to \mathcal{O}^\otimes$ is a trivial Kan fibration (Lemma 3.3.3.3), we conclude that $\phi : \mathcal{O}^\otimes \times \text{Fun}_{\mathcal{O}^\otimes}(\mathcal{O}^\otimes, \mathcal{C}^\otimes) \to \text{Alg}_\mathcal{O}(\mathcal{C})$ induces a categorical equivalence $\mathcal{O}^\otimes \times \text{Alg}_\mathcal{O}(\mathcal{C}) \to p_{\text{Alg}_\mathcal{O}(\mathcal{C})}$.

Definition 3.3.3.8. Let $\mathcal{O}^\otimes$ be a unital $\infty$-operad and $\mathcal{C}^\otimes \to \mathcal{O}^\otimes$ a fibration of generalized $\infty$-operads. We let $\text{Mod}_{\mathcal{O}^\otimes}(\mathcal{C}^\otimes)$ denote the fiber product

\[ \text{Mod}_{\mathcal{O}^\otimes}(\mathcal{C}^\otimes) \times_{p_{\text{Alg}_\mathcal{O}(\mathcal{C})}} (\mathcal{O}^\otimes \times \text{Alg}_\mathcal{O}(\mathcal{C})). \]

For every algebra object $A \in \text{Alg}_\mathcal{O}(\mathcal{C})$, we let $\text{Mod}_{\mathcal{O}^\otimes}(\mathcal{C}^\otimes) \{A\}$ denote the fiber product

\[ \text{Mod}_{\mathcal{O}^\otimes}(\mathcal{C}^\otimes) \times_{p_{\text{Alg}_\mathcal{O}(\mathcal{C})}} \{A\} \simeq \text{Mod}_{\mathcal{O}^\otimes}(\mathcal{C}^\otimes) \times_{\text{Alg}_\mathcal{O}(\mathcal{C})} \{A\}. \]
We will refer to \( \text{Mod}_A^O(\mathcal{C})\) as the infinite-operad of \( O \)-module objects over \( A \).

We can now state the main result of this section as follows:

**Theorem 3.3.3.9.** Let \( p : \mathcal{C} \to \mathcal{O} \) be a fibration of infinite-operads, where \( \mathcal{O} \) is coherent, and let \( A \in \text{Alg}_O(\mathcal{C}) \). Then the induced map \( \text{Mod}_A^O(\mathcal{C}) \to \mathcal{O} \) is a fibration of infinite-operads.

The main ingredient in the proof of Theorem 3.3.3.9 is the following result, which we will prove at the end of this section.

**Proposition 3.3.3.10.** Let \( \mathcal{O} \) be a coherent infinite-operad, and \( \mathcal{C} \to \mathcal{O} \) be a map of generalized infinite-operads. Then the induced map \( q : \text{Mod}_A^O(\mathcal{C}) \to \mathcal{O} \) is again a map of generalized infinite-operads. Moreover, a morphism \( f \) in \( \text{Mod}_A^O(\mathcal{C}) \) is inert if and only if it satisfies the following conditions:

1. The morphism \( f_0 = q(f) : X \to Y \) is inert in \( \mathcal{O} \).
2. Let \( F : \mathcal{K}_O \times \text{Fun}((0), \mathcal{O}) \Delta^1 \to \mathcal{C} \) be the functor classified by \( f \). For every \( e_0 \)-Cartesian morphism \( \tilde{f} \) of \( \mathcal{K}_O \) lifting \( f_0 \) (in other words, for every lift \( \tilde{f} \) of \( f_0 \) such that \( e_1(\tilde{f}) \) is an equivalence: see part (4) of the proof of Proposition 3.3.3.18), the morphism \( F(\tilde{f}) \) of \( \mathcal{C} \) is inert.

We will obtain Theorem 3.3.3.9 by combining Proposition 3.3.3.10 with a few elementary observations.

**Lemma 3.3.3.11.** Let \( p : \mathcal{O} \to \mathcal{C} \) be a unital infinite-operad. Let \( X \) and \( Y \) be objects of \( \mathcal{C} \), lying over objects \( (m), (n) \in \text{Fin}_* \), and let \( \text{Map}_\mathcal{O}(X, Y) \) denote the summand of \( \text{Map}_{\mathcal{C}}(X, Y) \) corresponding to those maps which cover the null morphism \( (m) \to (\ast) \to (n) \) in \( \text{Fin}_* \). Then \( \text{Map}_\mathcal{O}(X, Y) \) is contractible.

**Proof.** Choose an inert morphism \( f : X \to Z \) covering the map \( (m) \to (\ast) \) in \( \text{Fin}_* \). We observe that composition with \( f \) induces a homotopy equivalence \( \text{Map}_\mathcal{O}(Z, Y) \to \text{Map}_\mathcal{O}(X, Y) \). Since \( \mathcal{O} \) is unital, the space \( \text{Map}_\mathcal{O}(Z, Y) \) is contractible. \( \square \)

**Lemma 3.3.3.12.** Let \( \mathcal{O} \) be a unital infinite-operad and let \( \mathcal{C} \to \mathcal{O} \) be a \( \mathcal{O} \)-operad family. Then the map \( \widetilde{\text{Alg}}_O(\mathcal{C}) \to \mathcal{O} \) is a categorical fibration. In particular, \( \widetilde{\text{Alg}}_O(\mathcal{C}) \) is an infinite-category.

**Proof.** The simplicial set \( \widetilde{\text{Alg}}_O(\mathcal{C}) \) can be described as \( (e_0)_*(\mathcal{K}_O \times \text{Fun}((1), \mathcal{O})) \mathcal{C} \). The desired result now follows from Proposition B.4.5 and Corollary 3.3.3.4. \( \square \)

**Remark 3.3.3.13.** In the situation of Lemma 3.3.3.12, the simplicial set \( \text{Alg}_O(\mathcal{C}) \) is a full simplicial subset of an infinite-category, and therefore also an infinite-category. Since \( \text{Alg}_O(\mathcal{C}) \) is evidently stable under equivalence in \( \widetilde{\text{Alg}}_O(\mathcal{C}) \), we conclude that the map \( \text{Alg}_O(\mathcal{C}) \to \mathcal{O} \) is also a categorical fibration.

**Lemma 3.3.3.14.** Let \( \mathcal{O} \) be a coherent infinite-operad, and let \( \mathcal{C} \to \mathcal{O} \) be a \( \mathcal{O} \)-operad family. Then the inclusion \( \mathcal{K}_O \to \mathcal{K}_O \) induces a categorical fibration \( \widetilde{\text{Mod}}_O(\mathcal{C}) \to \text{Alg}_O(\mathcal{C}) \).

**Proof.** Since \( \widetilde{\text{Mod}}_O(\mathcal{C}) \) and \( \text{Alg}_O(\mathcal{C}) \) are full subcategories stable under equivalence in \( \widetilde{\text{Mod}}_O(\mathcal{C}) \) and \( \widetilde{\text{Alg}}_O(\mathcal{C}) \), it suffices to show that the map \( \widetilde{\text{Mod}}_O(\mathcal{C}) \to \widetilde{\text{Alg}}_O(\mathcal{C}) \) has the right lifting property with respect to every trivial cofibration \( A \to B \) with respect to the Joyal model structure on \( (\text{Set}_{\Delta})/\mathcal{O} \). Unwinding the definitions, we are required to provide solutions to lifting problems of the form

\[
\begin{align*}
(A \times \text{Fun}((0), \mathcal{O})) \mathcal{K}_O & \xrightarrow{i} (B \times \text{Fun}((0), \mathcal{O})) \mathcal{K}_O \\
(B \times \text{Fun}((0), \mathcal{O})) \mathcal{K}_O & \xrightarrow{q} \text{Fun}((1), \mathcal{O}).
\end{align*}
\]
Since $q$ is a categorical fibration, it suffices to prove that the monomorphism $i$ is a categorical equivalence of simplicial sets. In other words, we need to show that the diagram

$$
A \times_{\text{Fun}(\{0\}, \mathcal{O}^\otimes)} \mathcal{K}^0_\mathcal{O} \longrightarrow A \times_{\text{Fun}(\{0\}, \mathcal{O}^\otimes)} \mathcal{K}_\mathcal{O}
$$

$$
B \times_{\text{Fun}(\{0\}, \mathcal{O}^\otimes)} \mathcal{K}^0_\mathcal{O} \longrightarrow B \times_{\text{Fun}(\{0\}, \mathcal{O}^\otimes)} \mathcal{K}_\mathcal{O}
$$

is a homotopy pushout square (with respect to the Joyal model structure). To prove this, it suffices to show that the vertical maps are categorical equivalences. Since $A \to B$ is a categorical equivalence, this follows from Corollary B.3.15, since the restriction maps $e_0^0 : \mathcal{K}^0_\mathcal{O} \to \mathcal{O}^\otimes_0$ and $e_0 : \mathcal{K}_\mathcal{O} \to \mathcal{O}^\otimes_0$ are flat categorical fibrations (Corollary 3.3.3.4).

\[\square\]

**Remark 3.3.3.15.** Let $\mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be as in Lemma 3.3.3.14. Since every morphism $f : X \to Y$ in $\mathcal{O}^\otimes$ with $X \in \mathcal{O}^\otimes_0$ is automatically null, the categorical fibration $\overline{\text{Mod}^\mathcal{O}(\mathcal{C})^\otimes} \to \overline{\text{pAlg}_{/ \mathcal{O}}(\mathcal{C})}$ induces an isomorphism $\overline{\text{Mod}^\mathcal{O}(\mathcal{C})^\otimes_0} \to \overline{\text{pAlg}_{/ \mathcal{O}}(\mathcal{C})_0}$.

**Remark 3.3.3.16.** In the situation of Definition 3.3.3.8, consider the pullback diagram

$$
\begin{array}{ccc}
\text{Mod}^\mathcal{O}(\mathcal{C})^\otimes & \longrightarrow & \overline{\text{Mod}^\mathcal{O}(\mathcal{C})^\otimes} \\
\downarrow \phi' & & \downarrow \phi \\
\mathcal{O}^\otimes \times \text{Alg}_{/ \mathcal{O}}(\mathcal{C}) & \longrightarrow & \overline{\text{pAlg}_{/ \mathcal{O}}(\mathcal{C})}.
\end{array}
$$

Since $\theta$ is a categorical fibration and $\mathcal{O}^\otimes \times \text{Alg}_{/ \mathcal{O}}(\mathcal{C})$ is an $\infty$-category, this diagram is a homotopy pullback square (with respect to the Joyal model structure). Remark 3.3.3.7 implies that $j'$ is a categorical equivalence, so $j$ is also a categorical equivalence. Using Proposition 3.3.3.10, we deduce that $\text{Mod}^\mathcal{O}(\mathcal{C})^\otimes \to \mathcal{O}^\otimes \times \text{Alg}_{/ \mathcal{O}}(\mathcal{C})$ is a fibration of generalized $\infty$-operads.

**Proof of Theorem 3.3.3.9.** It follows from Remark 3.3.3.16 that the map $\text{Mod}^\mathcal{O}(\mathcal{C})^\otimes \to \mathcal{O}^\otimes$ is a fibration of generalized $\infty$-operads. To complete the proof, it will suffice to show that $\text{Mod}^\mathcal{O}(\mathcal{C})^\otimes$ is itself an $\infty$-operad. According to Proposition 2.3.2.5, this is equivalent to the assertion that $\text{Mod}^\mathcal{O}(\mathcal{C})^\otimes_0$ is a contractible Kan complex. This is clear, since Remark 3.3.3.15 implies that $\theta'$ induces an isomorphism $\text{Mod}^\mathcal{O}(\mathcal{C})^\otimes_0 \to \text{Alg}_{/ \mathcal{O}}(\mathcal{C})$.

\[\square\]

We now turn to the proof of Proposition 3.3.3.10.

**Lemma 3.3.3.17.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad, let $X : X \to X'$ be an object of $\text{Fun}(\Delta^1, \mathcal{O}^\otimes)$, and let $e_0 : \text{Fun}(\Delta^1, \mathcal{O}^\otimes) \to \mathcal{O}^\otimes$ be given by evaluation at $0$.

1. For every inert morphism $f_0 : X \to Y$ in $\mathcal{O}^\otimes$, there exists an $e_0$-coCartesian morphism $f : X \to Y$ in $\text{Fun}(\Delta^1, \mathcal{O}^\otimes)$ lifting $f_0$.

2. An arbitrary morphism $f : X \to Y$ in $\text{Fun}(\Delta^1, \mathcal{O}^\otimes)$ lifting $f_0$ is $e_0$-coCartesian if and only if the following conditions are satisfied:

   i. The image of $f$ in $\text{Fun}(\{1\}, \mathcal{O}^\otimes)$ is inert.
(ii) Let \( \alpha : \langle m \rangle \to \langle m' \rangle \) be the morphism in \( \text{Fin}_\ast \) determined by \( X \), and let \( \beta : \langle n \rangle \to \langle n' \rangle \) be the morphism in \( \text{Fin}_\ast \) determined by \( Y \). Then \( f \) induces a diagram

\[
\begin{array}{c}
\langle m \rangle \\
\downarrow^{\alpha} \\
\langle m' \rangle \\
\downarrow^{\gamma} \\
\langle n' \rangle
\end{array}
\begin{array}{c}
\langle n \rangle \\
\downarrow^{\beta} \\
\langle n' \rangle
\end{array}
\]

with the property that \( \gamma^{-1}\{*\} = \alpha(\delta^{-1}\{*\}) \).

(3) If \( \overline{X} \in \mathcal{K}_O \) and \( f \) is \( e_0 \)-coCartesian, then \( \overline{Y} \in \mathcal{K}_O \) (the map \( f \) is then automatically coCartesian with respect to the restriction \( e_0|\mathcal{K}_O \)).

Proof. We note that the “only if” direction of (2) follows from the “if” direction together with (1), since a coCartesian lift \( f \) of \( f_0 \) is determined uniquely up to homotopy. We first treat the case where \( O \otimes = N(\text{Fin}_\ast) \).

Then we can identify \( X \) with \( \alpha \) with \( \beta \), and \( f_0 \) with an inert morphism \( \delta : \langle m \rangle \to \langle n \rangle \). Choose a map \( \gamma : \langle m' \rangle \to \langle n' \rangle \) which identifies \( \langle n' \rangle \) with the finite pointed set obtained from \( \langle m' \rangle \) by collapsing \( \alpha(\delta^{-1}\{*\}) \) to a point, so that we have a commutative diagram

\[
\begin{array}{c}
\langle m \rangle \\
\downarrow^{\alpha} \\
\langle m' \rangle \\
\downarrow^{\gamma} \\
\langle n' \rangle
\end{array}
\begin{array}{c}
\langle n \rangle \\
\downarrow^{\beta} \\
\langle n' \rangle
\end{array}
\]

as in the statement of (ii). By construction, the map \( \gamma \) is inert. The above diagram is evidently a pushout square in \( \text{Fin}_\ast \) and so therefore corresponds to a morphism morphism \( f \) in \( \text{Fun}(\Delta^1, N(\text{Fin}_\ast)) \) which is coCartesian with respect to the projection \( \text{Fun}(\Delta^1, N(\text{Fin}_\ast)) \to N(\text{Fin}_\ast) \). This completes the proof of (1) and the “if” direction of (2); assertion (3) follows from the observation that \( \beta \) is semi-inert whenever \( \alpha \) is semi-inert.

We now prove the “if” direction of (2) in the general case. Since \( f_0 \) is inert, we conclude (Proposition T.2.4.1.3) that \( f \) is \( e_0 \)-coCartesian if and only if it is coCartesian with respect to the composition

\[
\text{Fun}(\Delta^1, O^\otimes) \subset \text{Fun}(\Delta^1, N(\text{Fin}_\ast)) \to N(\text{Fin}_\ast).
\]

This map admits another factorization

\[
\text{Fun}(\Delta^1, O^\otimes) \overset{p}{\to} \text{Fun}(\Delta^1, N(\text{Fin}_\ast)) \overset{q}{\to} N(\text{Fin}_\ast).
\]

The first part of the proof shows that \( p(f) \) is \( q \)-coCartesian. Since \( f_0 \) is inert, condition (i) and Lemma 3.2.2.9 guarantee that \( f \) is \( p \)-coCartesian. Applying Proposition T.2.4.1.3, we deduce that \( f \) is \( (q \circ p) \)-coCartesian as desired.

To prove (1), we first choose a diagram

\[
\begin{array}{c}
\langle m \rangle \\
\downarrow^{\alpha} \\
\langle m' \rangle \\
\downarrow^{\gamma} \\
\langle n' \rangle
\end{array}
\begin{array}{c}
\langle n \rangle \\
\downarrow^{\beta} \\
\langle n' \rangle
\end{array}
\]

satisfying the hypotheses of (2). We can identify this diagram with a morphism \( \overline{f} \) in \( \text{Fun}(\Delta^1, N(\text{Fin}_\ast)) \). We will show that it is possible to choose a map \( f : \overline{X} \to \overline{Y} \) satisfying (i) and (ii), which lifts both \( f_0 \) and \( \overline{f} \).
Using the assumption that $O^\otimes$ is an $\infty$-operad, we can choose an inert morphism $f_1 : X' \to Y'$ lifting $\gamma$. Using the fact that the projection $O^\otimes \to \text{N}(\mathcal{Fin}_*)$ is an inner fibration, we obtain a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{f_0} & Y \\
\downarrow & & \downarrow \\
X' & \xrightarrow{f_1} & Y'
\end{array}
\]

in $O^\otimes$. To complete the proof, it suffices to show that we can complete the diagram by filling an appropriate horn $\Lambda^3_0 \subseteq \Delta^2$ to supply the dotted arrow. The existence of this arrow follows from the fact that $f_0$ is inert, and therefore coCartesian with respect to the projection $O^\otimes \to \text{N}(\mathcal{Fin}_*)$.

We now prove (3). Let $f : X \to Y$ be a morphism corresponding to a diagram as above, where $X$ is semi-inert; we wish to show that $Y$ is semi-inert. The first part of the proof shows that the image of $Y$ in $\text{N}(\mathcal{Fin}_*)$ is semi-inert. It will therefore suffice to show that for any inert morphism $g : Y' \to Z$, if the image of $g \circ Y$ in $\text{N}(\mathcal{Fin}_*)$ is inert, then $g \circ Y$ is inert. We note that $g \circ Y \circ f_0 \simeq g \circ f_1 \circ X$ has inert image in $\text{N}(\mathcal{Fin}_*)$; since $X$ is semi-inert we deduce that $g \circ Y \circ f_0$ is inert. Since $f_0$ is inert, we deduce from Proposition T.2.4.1.7 that $g \circ Y$ is inert as desired. \hfill \Box

For the remainder of this section, we will assume that the reader is familiar with the language of categorical patterns developed in Appendix B.4. Let $\mathcal{P}$ denote the categorical pattern $(M, T, \{\sigma_\alpha : \Delta^1 \times \Delta^1 \to O^\otimes\}_{\alpha \in A})$ on $O^\otimes$ where $M$ is the collection of inert morphisms in $O^\otimes$, $T$ is the collection of all 2-simplices in $O^\otimes$, and $A$ is the collection of all diagrams of inert morphisms in $O^\otimes$ which cover a diagram

\[
\begin{array}{ccc}
\langle m \rangle & \xrightarrow{m'} & \langle n \rangle \\
\downarrow & & \downarrow \\
\langle m' \rangle & \xrightarrow{n'} & \langle n' \rangle
\end{array}
\]

in $\mathcal{Fin}_*$ which induces a bijection $\langle m' \rangle^\otimes \coprod_{\langle m' \rangle^\otimes} \langle n \rangle^\otimes \to \langle m \rangle^\otimes$. We will regard $(\text{Set}_\Delta^+)_{/\mathcal{P}} = (\text{Set}_\Delta^+)_{/O^\otimes}$ as endowed with the model structure of Theorem B.0.20. Let $M'$ denote the collection of inert morphisms in $X_0$, so that the construction $X \mapsto X \times_{\text{Fun}(\{0\},O^\otimes)} X_0, M'$ determines a functor $F : (\text{Set}_\Delta^+)_{/\mathcal{P}} \to (\text{Set}_\Delta^+)_{/\mathcal{P}}$. The functor $F$ admits a right adjoint $G$. By construction, if $\mathcal{C}^\otimes \to O^\otimes$ is a fibration of generalized $\infty$-operads, then $(\text{C}^\otimes_\Delta^\otimes)$ can be identified with the pair $(\text{Mod}^\otimes(\mathcal{C}), M'')$, where $M''$ is the collection of edges in $\text{Mod}^\otimes(\mathcal{C})$ satisfying condition (2) of Proposition 3.3.3.10. Unwinding the definitions, we see that an object $X \in (\text{Set}_\Delta^+)_{/O^\otimes}$ is fibrant if and only if the underlying map $X \to O^\otimes$ is a map of generalized $\infty$-operads and the collection of marked edges of $X$ coincides with the collection of inert morphisms in $X$. We can therefore reformulate Proposition 3.3.3.10 as follows:

\(\ast\) The functor $G : (\text{Set}_\Delta^+)_{/\mathcal{P}} \to (\text{Set}_\Delta^+)_{/\mathcal{P}}$ carries fibrant objects to fibrant objects.

This is an immediate consequence of the following stronger assertion:

**Proposition 3.3.3.18.** Let $O^\otimes$ be a coherent $\infty$-operad, let $M_0$ denote the collection of all inert morphisms in $O^\otimes$, and let $M$ denote the collection of all inert morphisms in $X_0$. Then the construction

\[
X \mapsto X \times_{O^\otimes \otimes} (X_0, M')
\]

determines a left Quillen functor from $(\text{Set}_\Delta^+)_{/\mathcal{P}}$ to itself.

**Proof.** It will suffice to show that the map $X_0 \to O^\otimes \otimes O^\otimes$ satisfies the hypotheses of Theorem B.4.2:

1. The evaluation map $e_0 : X_0 \to O^\otimes$ is a flat categorical fibration. This follows from our assumption that $O^\otimes$ is coherent.
3.3. **MODULES OVER \(\infty\)-OPERADS**

(2) The collections of inert morphisms in \(\mathcal{O}^\odot\) and \(\mathcal{K}_\mathcal{O}\) contain all equivalences and are closed under composition. This assertion is clear from the definitions.

(3) For every 2-simplex \(\sigma\) of \(\mathcal{K}_\mathcal{O}\), if \(e_0(\sigma)\) is thin, then \(e_1(\sigma)\) thin. Moreover, a 2-simplex \(\Delta^2 \to \mathcal{K}_\mathcal{O}\) is thin if its restriction to \(\Delta^{(0,1)}\) is thin. These assertions are clear, since the categorical pattern \(\mathcal{P}_{\mathcal{O}^\odot}^{\text{fam}}\) designates every 2-simplex as thin.

(4) For every inert edge \(\Delta^1 \to \text{Fun}(\{0\}, \mathcal{O}^\odot)\), the induced map \(\mathcal{K}_\mathcal{O} \times_{\text{Fun}(\{0\}, \mathcal{O}^\odot)} \Delta^1 \to \Delta^1\) is a Cartesian fibration. To prove this, it suffices to show that if \(X\) is an object of \(\mathcal{K}_\mathcal{O}\) corresponding to a semi-inert morphism \(X \to X'\) in \(\mathcal{O}^\odot\), and \(f : Y \to X\) is an inert morphism in \(\mathcal{O}^\odot\), then we can lift \(f\) to an \(e_0\)-Cartesian morphism \(\overline{f} : \overline{Y} \to \overline{X}\). According to Corollary T.2.4.7.12, we can lift \(f\) to a morphism \(\overline{f} : \overline{Y} \to \overline{X}\) in \(\text{Fun}(\Delta^1, \mathcal{O}^\odot)\) which is \(e_0\)-coCartesian, where \(e_0 : \text{Fun}(\Delta^1, \mathcal{O}^\odot) \to \mathcal{O}^\odot\) is given by evaluation at 0. To complete the proof, it suffices to show that \(\overline{Y}\) belongs to \(\mathcal{K}_\mathcal{O}\). We can identify \(\overline{f}\) with a commutative diagram

\[
\begin{align*}
Y & \xrightarrow{f} X \\
\overline{Y} & \xrightarrow{\overline{f}} \overline{X} \\
Y' & \xrightarrow{f'} X'
\end{align*}
\]

in \(\mathcal{O}^\odot\); we wish to prove that the morphism \(\overline{Y}\) is semi-inert. Since \(\overline{f}\) is \(e_0\)-Cartesian, Corollary T.2.4.7.12 implies that \(f'\) is an equivalence. We can therefore identify \(\overline{Y}\) with \(f' \circ \overline{Y} \simeq X \circ f\), which is inert by virtue of Remark 3.3.1.3. This completes the verification of condition (4) and establishes the following criterion: if \(\overline{f}\) is a morphism in \(\mathcal{K}_\mathcal{O}\) such that \(f = e_0(\overline{f})\) is inert, the following conditions are equivalent:

(i) The map \(\overline{f}\) is locally \(e_0\)-Cartesian.

(ii) The map \(\overline{f}\) is \(e_0\)-Cartesian.

(iii) The morphism \(e_1(\overline{f})\) is an equivalence in \(\mathcal{O}^\odot\).

(5) Let \(p : \Delta^1 \times \Delta^1 \to \text{Fun}(\{0\}, \mathcal{O}^\odot)\) be one of the diagrams specified in the definition of the categorical pattern \(\mathcal{P}_1\). Then the restriction of \(e_0\) determines a coCartesian fibration \((\Delta^1 \times \Delta^1) \times_{\text{Fun}(\{0\}, \mathcal{O}^\odot)} \mathcal{K}_\mathcal{O} \to \Delta^1 \times \Delta^1\). This follows immediately from Lemma 3.3.3.17.

(6) Let \(p : \Delta^1 \times \Delta^1 \to \text{Fun}(\{0\}, \mathcal{O}^\odot)\) be one of the diagrams specified in the definition of the categorical pattern \(\mathcal{P}_{\text{fam}}\) and let \(s\) be a coCartesian section of the projection \((\Delta^1 \times \Delta^1) \times_{\text{Fun}(\{0\}, \mathcal{O}^\odot)} \mathcal{K}_\mathcal{O} \to \Delta^1 \times \Delta^1\). Then the composite map

\[q : \Delta^1 \times \Delta^1 \xrightarrow{s} (\Delta^1 \times \Delta^1) \times_{\text{Fun}(\{0\}, \mathcal{O}^\odot)} \mathcal{K}_\mathcal{O} \to \mathcal{K}_\mathcal{O}\]

is one of the diagrams specified in the definition of the categorical pattern \(\mathcal{P}_{\text{Fun}(\{1\}, \mathcal{O}^\odot)}\). It follows from Lemma 3.3.3.17 that \(q\) carries each morphism in \(\Delta^1 \times \Delta^1\) to an inert morphism in \(\text{Fun}(\{1\}, \mathcal{O}^\odot)\). Unwinding the definitions (and using the criterion provided by Lemma 3.3.3.17), we are reduced to verifying the following simple combinatorial fact: given a semi-inert morphism \(\langle m \rangle \to \langle k \rangle\) in \(\text{Fin}_s\) and a commutative diagram of inert morphisms

\[
\begin{array}{ccc}
\langle m \rangle & \xrightarrow{n} & \langle n \rangle \\
\downarrow & & \downarrow \\
\langle m' \rangle & \xrightarrow{n'} & \langle n' \rangle
\end{array}
\]
which induces a bijection \( (n) \circ \coprod_{(m')} (m') \circ \rightarrow (m) \circ \), the induced diagram

\[
\begin{array}{c}
\langle k \rangle \\
\downarrow \\
\langle m' \rangle \coprod_{(m)} \langle k \rangle
\end{array} \rightarrow 
\begin{array}{c}
\langle n \rangle \coprod_{(m)} \langle k \rangle \\
\downarrow \\
\langle n' \rangle \coprod_{(m)} \langle k \rangle
\end{array}
\]

has the same property.

(7) Suppose we are given a commutative diagram

\[
\begin{array}{ccc}
Y & \xrightarrow{f} & X \\
\downarrow{g} & & \downarrow{h} \\
Z & \xrightarrow{h} & Y
\end{array}
\]

in \( K_\mathcal{O} \), where \( g \) is locally \( e_0 \)-Cartesian, \( e_0(g) \) is inert, and \( e_0(f) \) is an equivalence. We must show that \( f \) is inert if and only if \( h \) is inert. Consider the underlying diagram in \( \mathcal{O} \circ \)

\[
\begin{array}{ccc}
X_0 & \xrightarrow{f_0} & Y_0 & \xrightarrow{g_0} & Z_0 \\
\downarrow{f_1} & & \downarrow{g_1} & & \downarrow{h_0} \\
X_1 & \xrightarrow{h} & Y_1 & \xrightarrow{g_1} & Z_1.
\end{array}
\]

Since \( f_0 \) is an equivalence and \( g_0 \) is inert, \( h_0 = g_0 \circ f_0 \) is inert. It will therefore suffice to prove that \( f_1 \) is inert if and only if \( h_1 = g_1 \circ f_1 \) is inert. For this, it suffices to show that \( g_1 \) is an equivalence in \( \mathcal{O} \circ \). This follows from the proof of (4), since \( g \) is assumed to be locally \( e_0 \)-Cartesian.

(8) Suppose we are given a commutative diagram

\[
\begin{array}{ccc}
Y & \xrightarrow{f} & X \\
\downarrow{g} & & \downarrow{h} \\
Z & \xrightarrow{h} & Y
\end{array}
\]

in \( K_\mathcal{O} \) where \( f \) is \( e_0 \)-coCartesian, \( e_0(f) \) is inert, and \( e_0(g) \) is an equivalence. We must show that \( g \) is inert if and only if \( h \) is inert. Consider the underlying diagram in \( \mathcal{O} \circ \)

\[
\begin{array}{ccc}
X_0 & \xrightarrow{f_0} & Y_0 & \xrightarrow{g_0} & Z_0 \\
\downarrow{f_1} & & \downarrow{g_1} & & \downarrow{h_1} \\
X_1 & \xrightarrow{h} & Y_1 & \xrightarrow{g_1} & Z_1.
\end{array}
\]

Since \( f_0 \) and \( f_1 \) are inert (Lemma 3.3.3.17), Propositions T.5.2.8.6 and 2.1.2.4 guarantee that \( g_0 \) is inert if and only if \( h_0 \) is inert, and that \( g_1 \) is inert if and only if \( h_1 \) is inert. Combining these facts, we conclude that \( g \) is inert if and only if \( h \) is inert.

\[\square\]

We close this section by describing the structure of the module \( \infty \)-categories \( \text{Mod}_{\mathcal{O}}(\mathcal{C}) \) in the simplest case, where \( \mathcal{O} \circ \) is the \( \infty \)-operad \( \mathcal{E}_0 \circ \) of Example 2.1.1.19. Recall that \( \mathcal{E}_0 \circ \) is coherent (Example 3.3.1.13).
Proposition 3.3.3.19. Let \( q : \mathcal{C} \to \mathcal{E}_0 \) be a fibration of \( \infty \)-operads. Then the canonical map
\[
\text{Mod}^p_{\mathcal{E}_0}(\mathcal{C}) \to \mathcal{P}\text{Alg}_{/\mathcal{E}_0}(\mathcal{C}) \times \mathcal{C} = \text{Alg}_{/\mathcal{E}_0}(\mathcal{C}) \times \mathcal{C}
\]
is a trivial Kan fibration. In particular, for every \( \mathcal{E}_0 \)-algebra object \( A \) of \( \mathcal{C} \), the forgetful functor
\[
\text{Mod}^p_{\mathcal{E}_0}(\mathcal{C}) \to \mathcal{C}
\]
is an equivalence of \( \infty \)-categories.

Proof. There is a canonical isomorphism of simplicial sets \( \mathcal{X}_{\mathcal{E}_0} \times \mathcal{C} \simeq \mathcal{C}_0 \times \Delta^1 \). Let \( A \) be the full subcategory of \( \mathcal{C}_0 \times \Delta^1 \) spanned by \( (0), 0 \) together with the objects \( (n), 1 \) for \( n \geq 0 \). Unwinding the definitions, we can identify \( \text{Fun}_{\mathcal{E}_0}(\mathcal{E}_0 \times \Delta^1, \mathcal{C}^\otimes) \) spanned by those functors \( F \) which satisfy the following conditions:

(i) The restriction \( F|_{\mathcal{E}_0} \times (0) \) is an \( \mathcal{E}_0 \)-algebra object \( \mathcal{C}^\otimes \).

(ii) The functor \( F \) is a \( q \)-right Kan extension of \( F|_A \).

Using Proposition T.4.3.2.15, we deduce that the restriction functor
\[
\text{Mod}^p_{\mathcal{E}_0}(\mathcal{C}) \to \text{Fun}_{\mathcal{E}_0}(A, \mathcal{C}^\otimes) \times \text{Fun}_{\mathcal{E}_0}(\mathcal{E}_0 \times \{0\}, \mathcal{C}) \text{Alg}_{/\mathcal{E}_0}(\mathcal{C})
\]
is a trivial Kan fibration. It therefore suffices to show that the map
\[
\text{Fun}_{\mathcal{E}_0}(A, \mathcal{C}^\otimes) \to \text{Fun}_{\mathcal{E}_0}(\mathcal{E}_0 \times \{0\}, \mathcal{C}) \times \mathcal{C}
\]
is a trivial Kan fibration. Since \( \mathcal{E}_0 \) contains \( \{0\} \) as an initial object and \( A \) is isomorphic to the cone \( (\mathcal{E}_0^\otimes)^\circ \), the inclusion
\[
A_0 = (\{0\} \times \Delta^1) \coprod_{\{0\} \times \{1\}} \mathcal{C} \subseteq A
\]
is a categorical equivalence. Since \( q \) is a categorical fibration, the restriction map
\[
\text{Fun}_{\mathcal{E}_0}(A, \mathcal{C}^\otimes) \to \text{Fun}_{\mathcal{E}_0}(A_0, \mathcal{C}^\otimes)
\]
is a trivial Kan fibration. We are therefore reduced to proving that the restriction map
\[
\phi : \text{Fun}_{\mathcal{E}_0}(A_0, \mathcal{C}^\otimes) \to \text{Fun}_{\mathcal{E}_0}(\mathcal{E}_0^\otimes \times \{0\}, \mathcal{C}) \times \mathcal{C}
\]
is a trivial Kan fibration. The map \( \phi \) is a pullback of the evaluation map
\[
\text{Fun}_{\mathcal{E}_0}(\Delta^1, \mathcal{C}^\otimes) \to \text{Fun}_{\mathcal{E}_0}(\{0\}, \mathcal{C}^\otimes) = \mathcal{C},
\]
which is a trivial Kan fibration by virtue of Proposition T.4.3.2.15 (since every object of \( \mathcal{C}^\otimes_{\{0\}} \) is \( \phi \)-final). \( \square \)

### 3.4 General Features of Module \( \infty \)-Categories

Let \( A \) be a commutative ring. Then the relative tensor product functor \( (M, N) \mapsto M \otimes_A N \) endows the category \( \text{Mod}_A \) of \( A \)-modules with the structure of a symmetric monoidal category. This symmetric monoidal structure has the following features:

1. The category \( \text{CAlg}(\text{Mod}_A) \) of commutative algebra objects of \( \text{Mod}_A \) is equivalent to the category of \( A \)-algebras: that is, the category whose objects are commutative rings \( B \) equipped with a ring homomorphism \( A \to B \).
(2) Let $Ab$ denote the category of abelian groups. There is an evident forgetful functor $\theta : \text{Mod}_A \to Ab$. When $A$ is the ring of integers $\mathbb{Z}$, the functor $\theta$ is an equivalence of categories.

(3) The category $\text{Mod}_A$ admits small limits and colimits. Moreover, the forgetful functor $\theta : \text{Mod}_A \to Ab$ preserves all small limits and colimits.

Our goal in this section is to prove analogues of assertions (1), (2) and (3) in the $\infty$-categorical context. We will replace the symmetric monoidal category of abelian groups by an arbitrary fibration of $\infty$-operads $\theta : \text{Mod}_A^\otimes \to \mathcal{O}^\otimes$ defined in §3.3.3. We will prove the following:

(1’) There is an equivalence of $\infty$-categories $\text{Alg}_{/\mathcal{O}}(\text{Mod}_A^\otimes(\mathcal{C})) \to \text{Alg}_{/\mathcal{O}}(\mathcal{C})_{/A}$ (Corollary 3.4.1.7).

(2’) There is a forgetful functor $\theta : \text{Mod}_A^\otimes(\mathcal{C}) \to \mathcal{C}^\otimes$. If $A$ is a trivial $\mathcal{O}$-algebra (Definition 3.2.1.7), then $\theta$ is an equivalence of $\infty$-operads (Proposition 3.4.2.1).

(3’) Let $X \in \mathcal{O}$ be an object such that the fiber $\mathcal{C}_X$ admits $K$-indexed limits, for some simplicial set $K$. Then the $\infty$-category $\text{Mod}_A^\otimes(\mathcal{C})_X$ admits $K$-indexed limits. Moreover, $\theta$ restricts to a functor $\text{Mod}_A^\otimes(\mathcal{C})_X \to \mathcal{C}_X$ which preserves $K$-indexed limits (Corollary 3.4.3.6).

We will prove assertions (1’) and (2’) in §3.4.1 and §3.4.2, respectively. Assertion (3’) will be deduced from a more general assertion concerning limits relative to the forgetful functor $\theta' : \text{Mod}_A^\otimes(\mathcal{C}) \to \mathcal{O}^\otimes \times \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ (Theorem 3.4.3.1) which we prove in §3.4.3. There is an analogous statement for relative colimits (Theorem 3.4.4.3), which we will prove in §3.4.4. However, both the statement and the proof are considerably more involved: we must assume not only that the relevant colimits exist in the underlying $\infty$-category $\mathcal{C}$, but that they are operadic colimits in the sense of §3.1.1. Nevertheless, we will be able to use Theorem 3.4.4.3 to establish an analogue of (3’) for colimit diagrams, under some mild assumptions on the fibration $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ (see, for example, Theorem 3.4.4.2).

### 3.4.1 Algebra Objects of $\infty$-Categories of Modules

Let $\mathcal{C}$ be a symmetric monoidal category, let $A$ be a commutative algebra object of $\mathcal{C}$, and let $\mathcal{D} = \text{Mod}_A(\mathcal{C})$ be the category of $A$-modules in $\mathcal{C}$. Under some mild hypotheses, the category $\mathcal{D}$ inherits the structure of a symmetric monoidal category. Moreover, one can show the following:

(1) The forgetful functor $\theta : \mathcal{D} \to \mathcal{C}$ induces an equivalence of categories from the category of commutative algebra objects $\text{CAlg}(\mathcal{D})$ to the category $\text{CAlg}(\mathcal{C})_{/A}$ of commutative algebra objects $A' \in \text{CAlg}(\mathcal{D})$ equipped with a map $A \to A'$.

(2) Given a commutative algebra object $B \in \text{CAlg}(\mathcal{D})$, the category of $B$-modules in $\mathcal{D}$ is equivalent to the category of $\theta(B)$-modules in $\mathcal{C}$.

Our goal in this section is to obtain $\infty$-categorical analogues of the above statements for algebras over an arbitrary coherent $\infty$-operad (Corollaries 3.4.1.7 and 3.4.1.9). Before we can state our results, we need to introduce a bit of terminology.

**Notation 3.4.1.1.** Let $p : \mathcal{O}^\otimes \to N(\text{Fin}_*)$ be an $\infty$-operad, and let $\mathcal{O}_\mathcal{D} \subseteq \text{Fun}(\Delta^1, \mathcal{O}^\otimes)$ be defined as in Notation 3.3.2.1. We let $\mathcal{O}_\mathcal{D}^\otimes$ denote the $\infty$-category of pointed objects of $\mathcal{O}^\otimes$: that is, the full subcategory of $\text{Fun}(\Delta^1, \mathcal{O}^\otimes)$ spanned by those morphisms $X \to Y$ such that $X$ is a final object of $\mathcal{O}^\otimes$ (which is equivalent to the requirement that $p(X) = \{0\}$). If $\mathcal{O}^\otimes$ is unital, then a diagram $\Delta^1 \to \mathcal{O}^\otimes$ belongs to $\mathcal{O}_\mathcal{D}^\otimes \subseteq \text{Fun}(\Delta^1, \mathcal{O}^\otimes)$ if and only if it is a left Kan extension of its restriction to $\{1\}$. In this case, Proposition T.4.3.2.15 implies that evaluation at $\{1\}$ induces a trivial Kan fibration $e : \mathcal{O}^\otimes \to \mathcal{O}^\otimes$. We let $s : \mathcal{O}^\otimes \to \mathcal{O}^\otimes_\mathcal{D}$ denote a section of $e$, and regard $s$ as a functor from $\mathcal{O}^\otimes$ to $\text{Fun}(\Delta^1, \mathcal{O}^\otimes)$. We observe that there is a canonical natural transformation...
3.4. GENERAL FEATURES OF MODULE $\infty$-CATEGORIES

$s \to \delta$, where $\delta$ is the diagonal embedding $O^\otimes \to \text{Fun}(\Delta^1, O^\otimes)$. We regard this natural transformation as defining a map

$$\gamma_{O^\otimes} : O^\otimes \times \Delta^1 \to \mathcal{K}_O.$$  

**Remark 3.4.1.2.** More informally, the map $\gamma_{O^\otimes}$ can be described as follows. If $X \in O^\otimes$, then

$$\gamma_{O^\otimes}(X, i) = \begin{cases} 
\text{id}_X \in \mathcal{K}_O & \text{if } i = 1 \\
(f : 0 \to X) \in \mathcal{K}_O & \text{if } i = 0.
\end{cases}$$

Here 0 denotes a zero object of $O^\otimes$.

Let $O^\otimes$ be a coherent $\infty$-operad and let $C^\otimes \to O^\otimes$ be a fibration of generalized $\infty$-operads. Unwinding the definitions, we see that giving an $O$-algebra in $\text{Mod}_{O^\otimes}(C)$ is equivalent to giving a commutative diagram of simplicial sets

$$\xymatrix{ \mathcal{K}_O \ar[d]_f \ar[r]^{\epsilon_1} & C^\otimes \ar[d]_{\epsilon_1} \\
O^\otimes .}$$

such that $f$ preserves inert morphisms. Composing with the map $\gamma_O$ of Notation 3.4.1.1, we obtain a map

$$\text{Alg}_{/ O}(\text{Mod}^O(C)) \to \text{Fun}(\Delta^1, \text{Alg}_{/ O}(C)).$$

Our main results can be stated as follows:

**Proposition 3.4.1.3.** Let $O^\otimes$ be a coherent $\infty$-operad, and let $q : C^\otimes \to O^\otimes$ be a fibration of $\infty$-operads. Then the construction above determines a categorical equivalence

$$\text{Alg}_{/ O}(\text{Mod}^O(C)) \to \text{Fun}(\Delta^1, \text{Alg}_{/ O}(C)).$$

**Proposition 3.4.1.4.** Let $O^\otimes$ be a coherent $\infty$-operad, let $p : C^\otimes \to O^\otimes$ be a fibration of $\infty$-operads, and let $A \in \text{Alg}_{/ O}(C)$. Then the forgetful functor $\text{Mod}^O(A)(C)^\otimes \to C^\otimes$ induces a homotopy pullback diagram of $\infty$-categories

$$\xymatrix{ \text{Mod}^O(\text{Mod}^O(A)(C))^\otimes \ar[r] \ar[d] & \text{Mod}^O(C)^\otimes \ar[d] \\
\text{Alg}_{/ O}(\text{Mod}^O(A)(C)) 	imes O^\otimes \ar[r] & \text{Alg}_{/ O}(C) \times O^\otimes.}$$

We defer the proofs of Proposition 3.4.1.3 and 3.4.1.4 until the end of this section.

**Corollary 3.4.1.5.** Let $O^\otimes$ be a coherent $\infty$-operad and let $C^\otimes \to O^\otimes$ be a fibration of $\infty$-operads. The composition

$$\theta : \text{Alg}_{/ O}(\text{Mod}^O(C)) \to \text{Alg}_{/ O}(\text{Mod}^O(C)) \to \text{Fun}(\Delta^1, \text{Alg}_{/ O}(C))$$

is an equivalence of $\infty$-categories.

**Proof.** Combine Proposition 3.4.1.3 with Remark 3.3.3.16. □

**Remark 3.4.1.6.** Let $\theta : \text{Alg}_{/ O}(\text{Mod}^O(C)) \to \text{Fun}(\Delta^1, \text{Alg}_{/ O}(C))$ be the categorical equivalence of Corollary 3.4.1.5. Composing with the map $\text{Fun}(\Delta^1, \text{Alg}_{/ O}(C)) \to \text{Alg}_{/ O}(C)$ given by evaluation at $\{0\}$, we obtain a map $\theta_0 : \text{Alg}_{/ O}(\text{Mod}^O(C)) \to \text{Alg}_{/ O}(C)$. Unwinding the definitions, we see that $\theta_0$ factors as a composition

$$\text{Alg}_{/ O}(\text{Mod}^O(C)) \xrightarrow{\theta'_0} \text{Alg}_{/ O}(\text{Alg}_{/ O}(C) \times O) \xrightarrow{\theta''_0} \text{Alg}_{/ O}(C).$$
where $\theta''_A$ is induced by composition with the diagonal embedding $\mathcal{O}^\otimes \to \mathcal{O}^\otimes \times \mathcal{O}^\otimes$. In particular, if $A$ is a $\mathcal{O}$-algebra object of $\mathcal{C}$, then the the restriction of $\theta_0$ to $\text{Alg}_{/\mathcal{O}}(\text{Mod}_{A}^\otimes(\mathcal{C}))$ is a constant map taking the value $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$.

**Corollary 3.4.1.7.** Let $\mathcal{O}^\otimes$ be a coherent $\infty$-operad, let $\mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a fibration of $\infty$-operads, and let $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ be a $\mathcal{O}$-algebra object of $\mathcal{C}$. Then the categorical equivalence $\theta$ of Corollary 3.4.1.5 restricts to a categorical equivalence

$$\theta_A : \text{Alg}_{/\mathcal{O}}(\text{Mod}_{A}^\otimes(\mathcal{C})) \to \text{Alg}_{/\mathcal{O}}(\mathcal{C})^{A/}. \tag{Corollary 3.4.1.7}$$

**Proof.** Remark 3.4.1.6 guarantees that the restriction of $\theta$ carries $\text{Alg}_{/\mathcal{O}}(\text{Mod}_{A}^\otimes(\mathcal{C}))$ into $\text{Alg}_{/\mathcal{O}}(\mathcal{C})^{A/} \subseteq \text{Fun}(\Delta^1, \text{Alg}_{/\mathcal{O}}(\mathcal{C})^{A/})$. Consider the diagram

$$
\begin{array}{ccc}
\text{Alg}_{/\mathcal{O}}(\text{Mod}_{A}^\otimes(\mathcal{C})) & \longrightarrow & \text{Alg}_{/\mathcal{O}}(\text{Mod}^\otimes(\mathcal{C})) \\
\downarrow & & \downarrow \\
\Delta^0 & \longrightarrow & \text{Alg}_{/\mathcal{O}}(\text{Alg}_{/\mathcal{O}}(\mathcal{C}) \times \mathcal{O}) \\
\theta & \longrightarrow & \theta' \circ \text{Fun}(\{0\}, \text{Alg}_{/\mathcal{O}}(\mathcal{C})).
\end{array}
$$

The left square is a homotopy pullback, since it is a pullback square between fibrant objects in which the vertical maps are categorical fibrations. The right square is a homotopy pullback since both of the horizontal arrows are categorical equivalences ($\theta$ is a categorical equivalence by virtue of Corollary 3.4.1.5, and $\theta'$ is a categorical equivalence since it is left inverse to a categorical equivalence). It follows that the outer square is also a homotopy pullback, which is equivalent to the assertion that $\theta_A$ is a categorical equivalence (Proposition T.3.3.1.3). \hfill \square

**Corollary 3.4.1.8.** Let $\mathcal{O}^\otimes$ be a coherent $\infty$-operad, $p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ a fibration of $\infty$-operads, and $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ an algebra object. Then there is a canonical equivalence of $\infty$-categories

$$\text{Mod}^\otimes(\text{Mod}_{A}^\otimes(\mathcal{C}))^\otimes \to \text{Mod}^\otimes(\mathcal{C})^\otimes \times_{\text{Alg}_{/\mathcal{O}}(\mathcal{C})} \text{Alg}_{/\mathcal{O}}(\mathcal{C})^{A/}. \tag{Corollary 3.4.1.8}$$

**Proof.** Combine Proposition 3.4.1.4 with Corollary 3.4.1.7. \hfill \square

**Corollary 3.4.1.9.** Let $\mathcal{O}^\otimes$ be a coherent $\infty$-operad, $p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ a fibration of $\infty$-operads. Let $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$, let $\mathcal{B} \in \text{Alg}_{/\mathcal{O}}(\text{Mod}_{A}^\otimes(\mathcal{C}))$, and let $B \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ be the algebra object determined by $\mathcal{B}$. Then there is a canonical equivalence of $\infty$-operads

$$\text{Mod}_{\mathcal{B}}^\otimes(\text{Mod}_{A}^\otimes(\mathcal{C}))^\otimes \to \text{Mod}_{B}^\otimes(\mathcal{C})^\otimes. \tag{Corollary 3.4.1.9}$$

We now turn to the proof of Propositions 3.4.1.3 and 3.4.1.4. We will need a few preliminary results.

**Lemma 3.4.1.10.** Suppose we are given a commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{F} & \mathcal{D} \\
\downarrow p & & \downarrow q \\
\mathcal{E} & \to & \mathcal{E}
\end{array}
$$

where $p$ and $q$ are Cartesian fibrations and the map $F$ carries $p$-Cartesian morphisms to $q$-Cartesian morphisms. Let $D \in \mathcal{D}$ be an object, let $E = q(D)$, and let $\mathcal{E}_{D/} = \mathcal{E}_{\times_{\mathcal{D}} D/}$. Then:

1. The induced map $p' : \mathcal{E}_{D/} \to \mathcal{E}_{E/}$ is a Cartesian fibration.
(2) A morphism $f$ in $\mathcal{E}_{D/}$ is $p'$-Cartesian if and only if its image in $\mathcal{C}$ is $p$-Cartesian.

Proof. Let us say that a morphism in $\mathcal{E}_{D/}$ is special if its image in $\mathcal{C}$ is $p$-Cartesian. We first prove the “if” direction of (2) by showing that every special morphism of $\mathcal{E}_{D/}$ is $p$-Cartesian; we will simultaneously show that $p'$ is an inner fibration. For this, we must show that every lifting problem of the form

$$
\begin{array}{ccc}
\Lambda^n_i & \xrightarrow{g_0} & \mathcal{E}_{D/} \\
\downarrow \downarrow & & \downarrow \\
\Delta^n & \xrightarrow{g} & \mathcal{E}_{E/}
\end{array}
$$

admits a solution, provided that $n \geq 2$ and either $0 < i < n$ or $i = n$ and $g_0$ carries $\Delta^{(n-1,n)}$ to a special morphism $e$ in $\mathcal{E}_{D/}$. To prove this, we first use the fact that $p$ is an inner fibration (together with the observation that the image $e_0$ of $e$ in $\mathcal{C}$ is $p$-Cartesian when $i = n$) to solve the associated lifting problem

$$
\begin{array}{ccc}
\Lambda^n_i & \xrightarrow{g'_0} & \mathcal{E} \\
\downarrow \downarrow & & \downarrow \\
\Delta^n & \xrightarrow{g'} & \mathcal{E}.
\end{array}
$$

To extend this to solution of our original lifting problem, we are required to solve another lifting problem of the form

$$
\begin{array}{ccc}
\Lambda^{n+1}_{i+1} & \xrightarrow{g''_0} & \mathcal{D} \\
\downarrow \downarrow & & \downarrow \\
\Delta^{n+1} & \xrightarrow{g''} & \mathcal{E}.
\end{array}
$$

If $i < n$, the desired solution exists by virtue of our assumption that $q$ is an inner fibration. If $i = n$, then it suffices to observe that $g''_0(\Delta^{(n,n+1)}) = F(e_0)$ is a $q$-Cartesian morphism in $\mathcal{D}$.

To prove (1), it will suffice to show that for every object $\bar{C} \in \mathcal{E}_{D/}$ and every morphism $\bar{f}_0 : \bar{E} \to p'(\bar{C})$ in $\mathcal{E}_{E/}$, there exists a special morphism $\bar{f}$ in $\mathcal{E}_{D/}$ with $p'(\bar{f}) = \bar{f}_0$. We can identify $\bar{C}$ with an object $C \in \mathcal{C}$ together with a morphism $\alpha : D \to F(C)$ in $\mathcal{D}$, and we can identify $\bar{f}_0$ with a 2-simplex

$$
\begin{array}{ccc}
\bar{E}' & \xrightarrow{\bar{f}_0} & \bar{C}' \\
\downarrow \downarrow & & \downarrow \\
E & \xrightarrow{q(\alpha)} & p(C)
\end{array}
$$

in $\mathcal{E}$. Since $p$ is a Cartesian fibration, we can choose a $p$-Cartesian morphism $\bar{f} : \bar{C}' \to C$ with $p(\bar{f}) = \bar{f}_0$. In order to lift $\bar{f}$ to a special morphism $\bar{f} : \bar{C}' \to \bar{C}$, it suffices to complete the diagram

$$
\begin{array}{ccc}
F(C') & \xrightarrow{F(\bar{f})} & F(C) \\
\downarrow \downarrow & & \downarrow \\
D & \xrightarrow{\alpha} & F(C)
\end{array}
$$

to a 2-simplex of $\mathcal{D}$. This is possibly by virtue of our assumption that $F(\bar{f}_0)$ is $q$-Cartesian.

To complete the proof of (2), it will suffice to show that every $p'$-Cartesian morphism $\bar{f}' : \bar{C}' \to \bar{C}$ of $\mathcal{E}_{D/}$ is special. The proof of (1) shows that there exists a special morphism $\bar{f} : \bar{C}' \to \bar{C}$ with $p'(\bar{f}) = p'(\bar{f}')$. Since $\bar{f}$ is also $p'$-Cartesian, it is equivalent to $\bar{f}'$, so that $\bar{f}'$ is also special. \qed
Lemma 3.4.1.11. Suppose given a commutative diagram of ∞-categories

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
\downarrow{p} & & \downarrow{q} \\
\mathcal{E} & \xrightarrow{} & \mathcal{E}
\end{array}
\]

where \( p \) and \( q \) are Cartesian fibrations, and the map \( F \) carries \( p \)-Cartesian morphisms to \( q \)-Cartesian morphisms. Suppose furthermore that for every object \( E \in \mathcal{E} \), the induced functor \( F_E : \mathcal{C}_E \to \mathcal{D}_E \) is left cofinal. Then \( F \) is left cofinal.

Proof. In view of Theorem T.4.1.3.1, it suffices to show that for each object \( D \in \mathcal{D} \), the simplicial set \( \mathcal{C}_{D/} = \mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{D/} \) is weakly contractible. Let \( E \) denote the image of \( D \) in \( \mathcal{E} \); we observe that \( \mathcal{C}_{D/} \) comes equipped with a map \( p' : \mathcal{C}_{D/} \to \mathcal{E}_{E/} \). Moreover, the fiber of \( p' \) over the initial object \( \text{id}_E \in \mathcal{E}_{E/} \) can be identified with \( \mathcal{C}_{E} \times_{\mathcal{D}} \mathcal{D}_{D/} \), which is weakly contractible by virtue of our assumption that \( F_E \) is left cofinal (Theorem T.4.1.3.1). To prove that \( \mathcal{C}_{D/} \) is contractible, it will suffice to show that the inclusion \( i : p'^{-1}\{\text{id}_E\} \hookrightarrow \mathcal{C}_{D/} \) is a weak homotopy equivalence. We will prove something slightly stronger: the inclusion \( i \) is right cofinal. Since the inclusion \( \{\text{id}_E\} \to \mathcal{E}_{E/} \) is evidently right cofinal, it will suffice to show that \( p' \) is a Cartesian fibration (Proposition T.4.1.2.15). This follows from Lemma 3.4.1.10.

Lemma 3.4.1.12. Let \( q : \mathcal{C}^\odot \to \mathcal{O}^\odot \) be a fibration of ∞-operads, and let \( \alpha : \langle n \rangle \to \langle m \rangle \) be an inert morphism in \( \mathcal{F}_{\text{in}} \). Let \( \sigma \) denote the diagram

\[
\begin{array}{ccc}
\langle n \rangle & \xrightarrow{\alpha} & \langle m \rangle \\
\downarrow{\text{id}} & & \downarrow{\text{id}} \\
\langle n \rangle & \xrightarrow{\alpha} & \langle m \rangle
\end{array}
\]

in \( \mathcal{N}(\mathcal{F}_{\text{in}}) \), let \( K \simeq \Lambda^2_2 \) be the full subcategory of \( \Delta^1 \times \Delta^1 \) obtained by omitting the initial vertex, and let \( \sigma_0 = \sigma | K \). Suppose that \( \sigma_0 : K \to \mathcal{C}^\odot \) is a diagram lifting \( \sigma_0 \), corresponding to a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{\sigma} & X' \\
\downarrow & & \downarrow \\
Y' & \xrightarrow{\sigma'} & X'
\end{array}
\]

where \( \sigma' \) is inert. Then:

(1) Let \( \sigma : \Delta^1 \times \Delta^1 \to \mathcal{C}^\odot \) be an extension of \( \sigma_0 \) lifting \( \sigma \), corresponding to a commutative diagram

\[
\begin{array}{ccc}
Y & \xrightarrow{\pi} & X \\
\downarrow{\pi} & & \downarrow{\text{id}} \\
Y' & \xrightarrow{\pi'} & X'
\end{array}
\]

in \( \mathcal{C}^\odot \). Then \( \sigma \) is a \( q \)-limit diagram if and only if it satisfies the following conditions:

(i) The map \( \pi \) is inert.

(ii) Let \( \gamma : \langle n \rangle \to \langle k \rangle \) be an inert morphism in \( \mathcal{N}(\mathcal{F}_{\text{in}}) \) such that \( \alpha^{-1}\langle m \rangle^\circ \subseteq \gamma^{-1}\{*\} \), and let \( \tau : Y' \to Z \) be an inert morphism in \( \mathcal{C}^\odot \) lifting \( \gamma \). Then \( \tau \circ \beta : Y \to Z \) is an inert morphism in \( \mathcal{C}^\odot \).

(2) There exists an extension \( \sigma \) of \( \sigma_0 \) lying over \( \sigma \) which satisfies conditions (i) and (ii) of (1).
**Proof.** This is a special case of Lemma 3.4.3.15.

**Proof of Proposition 3.4.1.3.** We define a simplicial set $M$ equipped with a map $p : M \to \Delta^1$ so that the following universal property is satisfied: for every map of simplicial sets $K \to \Delta^1$, the set $\text{Hom}(_{\Delta^1} \text{Set}(K, M))$ can be identified with the collection of all commutative diagrams

$$
\begin{array}{ccc}
K \times \Delta^1 \{1\} & \longrightarrow & \mathcal{O}^\otimes \times \Delta^1 \\
\downarrow \quad \gamma_0 \downarrow & & \downarrow \\
K & \longrightarrow & \mathcal{X}_\mathcal{O}.
\end{array}
$$

The map $p$ is a Cartesian fibration, associated to the functor $\gamma_0$ from $M_1 \simeq \mathcal{O}^\otimes \times \Delta^1$ to $M_0 \simeq \mathcal{X}_\mathcal{O}$. We observe that $M$ is equipped with a functor $M \to \mathcal{O}^\otimes$, whose restriction to $M_1 \simeq \mathcal{O}^\otimes \times \Delta^1$ is given by projection onto the first factor and whose restriction to $M_0 \simeq \mathcal{X}_\mathcal{O}$ is given by evaluation at $\{1\}$.

We let $\mathcal{X}$ denote the full subcategory of $\text{Fun}_{\mathcal{O}^\otimes}(M, \mathcal{E}^\otimes)$ spanned by those functors $F$ satisfying the following pair of conditions:

(i) The functor $F$ is a $q$-left Kan extension of $F|M_0$.

(ii) The restriction $F|M_0 \in \text{Fun}_{\mathcal{O}^\otimes}(\mathcal{X}_\mathcal{O}, \mathcal{E}^\otimes)$ belongs to $\text{Alg}_{/ \mathcal{O}}(\text{Mod}^\mathcal{O}_{/ \mathcal{E}}(\mathcal{E}))$.

Since $p$ is a Cartesian fibration, condition (i) can be reformulated as follows:

(i') For every $p$-Cartesian morphism $f$ in $M$, the image $F(f)$ is a $q$-coCartesian morphism in $\mathcal{E}^\otimes$. Since the image of $f$ in $\mathcal{O}^\otimes$ is an equivalence, this is equivalent to the requirement that $F(f)$ is an equivalence in $\mathcal{E}^\otimes$.

Using Proposition T.4.3.2.15, we deduce that the restriction map $\mathcal{X} \to \text{Alg}_{/ \mathcal{O}}(\text{Mod}^\mathcal{O}_{/ \mathcal{E}}(\mathcal{E}))$ is a trivial Kan fibration. This restriction map has a section $s$, given by composition with the natural retraction $r : M \to M_0$. It follows that $s$ is a categorical equivalence, and that every object $F \in \mathcal{X}$ is equivalent $(F|M_0) \circ r$. We deduce that restriction to $M_1 \subseteq M$ induces a functor $\theta' : \mathcal{X} \to \text{Fun}(\Delta^1, \text{Alg}_{/ \mathcal{O}}(\mathcal{E}))$. We have a commutative diagram

$$
\begin{array}{ccc}
\text{Alg}_{/ \mathcal{O}}(\text{Mod}^\mathcal{O}_{/ \mathcal{E}}(\mathcal{E})) & \longrightarrow & \text{Fun}(\Delta^1, \text{Alg}_{/ \mathcal{O}}(\mathcal{E})) \\
\downarrow \quad \theta \downarrow & & \quad \downarrow \\
\mathcal{X} & \longrightarrow & \text{Fun}(\Delta^1, \text{Alg}_{/ \mathcal{O}}(\mathcal{E})).
\end{array}
$$

To complete the proof, it will suffice to show that $\theta'$ is a categorical equivalence. We will show that $\theta'$ is a trivial Kan fibration. In view of Proposition T.4.3.2.15, it will suffice to prove the following:

(a) A functor $F \in \text{Fun}_{\mathcal{O}^\otimes}(M, \mathcal{E}^\otimes)$ belongs to $\mathcal{X}$ if and only if $F_1 = F|M_1 \in \text{Fun}(\Delta^1, \text{Alg}_{/ \mathcal{O}}(\mathcal{E}))$ and $F$ is a $q$-right Kan extension of $F_1$.

(b) Every object $F_1 \in \text{Fun}_{\mathcal{O}^\otimes}(M_1, \mathcal{E}^\otimes)$ belonging to $\text{Fun}(\Delta^1, \text{Alg}_{/ \mathcal{O}}(\mathcal{E}))$ admits a $q$-right Kan extension of $F \in \text{Fun}_{\mathcal{O}^\otimes}(M, \mathcal{E}^\otimes)$.

To prove these claims, we will need a criterion for detecting whether a functor $F \in \text{Fun}_{\mathcal{O}^\otimes}(M, \mathcal{E}^\otimes)$ is a $q$-right Kan extension of $F_1 = F|M_1 \in \text{Fun}(\Delta^1, \text{Alg}_{/ \mathcal{O}}(\mathcal{E}))$ at an object $X \in M_0$. Let $\mathcal{X}$ correspond to a semi-inert morphism $\alpha : X' \to X$ in $\mathcal{O}^\otimes$, covering a morphism $\alpha : \langle m \rangle \to \langle n \rangle$ in $\text{N}(\text{Fin}_+)$. Let $\mathcal{D}$ denote the
\(\infty\)-category \((\mathcal{O}^\otimes \times \Delta^1) \times_{\mathcal{M}} \mathcal{F}_c\), so that \(\mathcal{D}\) is equipped with a projection \(\mathcal{D} \to \Delta^1\); we let \(\mathcal{D}_0\) and \(\mathcal{D}_1\) denote the fibers of this map. Form a pushout diagram

\[
\begin{array}{c}
\langle m \rangle \quad \langle n \rangle \\
\downarrow \quad \downarrow \\
\langle 0 \rangle \quad \langle k \rangle \\
\end{array}
\]

in \(\text{Fin}_*\), and choose an inert morphism \(\bar{\beta} : X' \to Y\) in \(\mathcal{O}^\otimes\) lying over \(\beta\). Let \(\bar{Y}\) denote the image of \(Y\) under our chosen section \(s : \mathcal{O}^\otimes \to \mathcal{O}^\otimes\), so we can identify \(\bar{Y}\) with a morphism \(0 \to Y\) in \(\mathcal{O}^\otimes\), where \(0\) is a zero object of \(\mathcal{O}^\otimes\). We can therefore lift \(\bar{\beta}\) to a morphism \(\tilde{\beta} : \bar{X} \to \bar{Y}\) in \(\mathcal{K}_0\), corresponding to a commutative diagram

\[
\begin{array}{c}
X' \quad \quad \pi \\
\downarrow \quad \downarrow \tilde{\beta} \\
0 \quad \quad \bar{Y} \\
\end{array}
\]

The pair \((Y, \bar{\beta})\) can be identified with an object of \(N_0\), which we will denote by \(\bar{Y}\). We claim that \(\bar{Y}\) is an initial object of \(N_0\). Unwinding the definitions, this is equivalent to the following assertion: for every object \(A \in \mathcal{O}^\otimes\), composition with \(\bar{\beta}\) induces a homotopy equivalence

\[
\phi : \text{Map}_{\mathcal{O}^\otimes}(Y, A) \to \text{Map}_{\mathcal{K}_0}(\bar{X}, s(A)).
\]

To prove this, we observe that \(\phi\) factors as a composition

\[
\text{Map}_{\mathcal{O}^\otimes}(Y, A) \xrightarrow{\phi'} \text{Map}_{\mathcal{K}_0}(\bar{Y}, s(A)) \xrightarrow{\phi''} \text{Map}_{\mathcal{K}_0}(\bar{X}, s(A)).
\]

The map \(\phi'\) is a homotopy equivalence because \(s\) is a categorical equivalence, and the map \(\phi''\) is a homotopy equivalence because \(\bar{f}\) is coCartesian with respect to the projection \(\mathcal{K}_0 \to \mathcal{K}_{N(\text{Fin}_*)}\).

We have an evident natural transformation \(\tilde{\gamma} : \bar{X} \to \text{id}_X\) in \(\mathcal{K}_0\). The pair \((X, \tilde{\gamma})\) determines an object \(\bar{Z} \in N_1\). We claim that \(\bar{Z}\) is an initial object of \(N_1\). Unwinding the definitions, we see that this is equivalent to the assertion that for every object \(A \in \mathcal{O}^\otimes\), composition with \(\tilde{\gamma}\) induces a homotopy equivalence

\[
\psi : \text{Map}_{\mathcal{O}^\otimes}(X, A) \to \text{Map}_{\mathcal{K}_0}(\bar{X}, \delta(A)),
\]

where \(\delta : \mathcal{O}^\otimes \to \mathcal{K}_0\) is the diagonal embedding. To prove this, we factor \(\psi\) as a composition

\[
\text{Map}_{\mathcal{O}^\otimes}(X, A) \xrightarrow{\psi'} \text{Map}_{\mathcal{K}_0}(\bar{X}, \delta(A)) \xrightarrow{\psi''} \text{Map}_{\mathcal{K}_0}(\bar{X}, \delta(A)).
\]

The map \(\psi'\) is a homotopy equivalence since \(\delta\) is fully faithful, and the map \(\psi''\) is a homotopy equivalence by virtue of Corollary T.5.2.8.18 (applied to the trivial factorization system on \(\mathcal{O}^\otimes\)).

Since \(N \to \mathcal{O}^\otimes \times \Delta^1\) is a left fibration, we can lift the map \(\langle Y, 0 \rangle \to \langle Y, 1 \rangle\) to a map \(e : \bar{Y} \to \bar{Y}'\) in \(N\). Since \(\bar{Z}\) is an initial object of \(N_1\), we can choose a map \(e' : \bar{Z} \to \bar{Y} \in N_1\). Let \(C \simeq \Lambda^2_3\) denote the full subcategory of \(\Delta^1 \times \Delta^1\) obtained by omitting the final vertex, so that \(e\) and \(e'\) together determine a map of simplicial sets \(C \to N\). Applying the dual of Lemma 3.4.1.11 to the diagram

\[
\begin{array}{c}
C \\
\downarrow \\
\Delta^1,
\end{array}
\]

we deduce that \(C \to N\) is right cofinal. We therefore arrive at the following:
3.4. GENERAL FEATURES OF MODULE ∞-CATEGORIES

(*) A functor $F \in \text{Fun}_{\text{FP}}(\mathcal{M}, \mathcal{C}^\otimes)$ is a $q$-right Kan extension of $F_1 = F|\mathcal{M}_1 \in \text{Fun}(\Delta^1, \text{Alg}/\mathcal{O}(\mathcal{C}))$ at an object $X \in \mathcal{K}_\mathcal{O}$ if and only if the induced diagram

$$
\begin{array}{ccc}
F(X) & \rightarrow & F_1(X, 1) \\
\downarrow & & \downarrow \\
F_1(Y, 0) & \rightarrow & F_1(Y, 1)
\end{array}
$$

is a $q$-limit diagram.

Moreover, Lemma T.4.3.2.13 yields the following:

(*') A functor $F_1 \in \text{Fun}(\Delta^1, \text{Alg}/\mathcal{O}(\mathcal{C}))$ admits a $q$-right Kan extension $F \in \text{Fun}_{\text{FP}}(\mathcal{M}, \mathcal{C}^\otimes)$ if and only if, for every object $X \in \mathcal{K}_\mathcal{O}$, the diagram

$$
\begin{array}{ccc}
F_1(X, 1) & \\
\downarrow & \\
F_1(Y, 0) & \rightarrow & F_1(Y, 1)
\end{array}
$$

can be extended to a $q$-limit diagram lying over the diagram

$$
\begin{array}{ccc}
X & \stackrel{\text{id}}{\rightarrow} & X \\
\downarrow & & \downarrow \\
Y & \stackrel{\text{id}}{\rightarrow} & Y.
\end{array}
$$

Assertion (b) follows immediately from (*') together with Lemma 3.4.1.12. Combining assertion (*) with Lemma 3.4.1.12, we deduce that a functor $F \in \text{Fun}_{\text{FP}}(\mathcal{M}, \mathcal{C}^\otimes)$ is a $q$-right Kan extension of $F_1 = F|\mathcal{M}_1 \in \text{Fun}(\Delta^1, \text{Alg}/\mathcal{O}(\mathcal{C}))$ if and only if the following conditions are satisfied:

(i') The restriction $F_1$ belongs to $\text{Fun}(\Delta^1, \text{Alg}/\mathcal{O}(\mathcal{C}))$. That is, $F$ carries every inert morphism in $\mathcal{O}^\otimes \times \{j\} \subseteq \mathcal{M}_1$ to an inert morphism in $\mathcal{C}^\otimes$, for $j \in \{0, 1\}$.

(ii') Let $X$ be as above. Then the induced morphism $F(X) \rightarrow F(Y, 0)$ is inert.

(iii') Let $X$ be as above, and suppose that we are given an inert morphism $\alpha' : \langle n \rangle \rightarrow \langle l \rangle$ such that the composite map $\alpha' \circ \alpha : \langle m \rangle \rightarrow \langle n' \rangle$ is surjective together with an inert morphism $\bar{\alpha}' : X \rightarrow X''$ lifting $\alpha'$. Then the composite map $F(X) \rightarrow F(X, 1) \rightarrow F(X'', 1)$ is an inert morphism in $\mathcal{C}^\otimes$.

To complete the proof, it will suffice to show that a functor $F \in \text{Fun}_{\text{FP}}(\mathcal{M}, \mathcal{C}^\otimes)$ satisfies conditions (i) and (ii) if and only if it satisfies conditions (i'), (ii'), and (iii').

Suppose first that $F$ satisfies (i) and (ii). We have already seen that $F$ must also satisfy (i'). To prove (ii'), we observe that the map $F(X) \rightarrow F(Y, 0)$ factors as a composition

$$
F(X) \rightarrow F(Y) \rightarrow F(Y, 0).
$$

The first map is inert because $F$ satisfies (ii) and $\bar{\beta} : X \rightarrow Y$ is an inert morphism in $\mathcal{K}_\mathcal{O}$. The second morphism is inert by virtue of assumption (i). Now suppose that we are given an inert morphism $X \rightarrow X''$ as in (iii'). We have a commutative diagram

$$
\begin{array}{ccc}
X & \rightarrow & X' \\
\downarrow & & \downarrow \\
X'' & \stackrel{\text{id}}{\rightarrow} & X''
\end{array}
$$
corresponding to an inert morphism \( \overline{X} \to \delta(X'') \) in \( \mathcal{K}_\circ \), and the map \( F(\overline{X}) \to F(X'',1) \) factors as a composition

\[
F(\overline{X}) \to F(\delta(X'')) \to F(X'',1).
\]

The first of these maps is inert by virtue of assumption (ii), and the second by virtue of assumption (i).

Now suppose that \( S \) satisfies (i'), (ii'), and (iii''); we wish to show that \( F \) satisfies (i) and (ii'). To prove (i), we must show that for every object \( X \in \mathcal{C} \), the morphisms \( F(s(X)) \to F(X,0) \) and \( F(\delta(X)) \to F(X,1) \) are inert in \( \mathcal{C} \). The first of these assertions is a special case of (ii'), and the second is a special case of (iii'').

To prove (ii), consider an arbitrary inert morphism \( \overline{\beta} : \overline{X} \to \overline{Y} \) in \( \mathcal{O}^\circ \), corresponding to a commutative diagram \( \sigma \):

\[
\begin{array}{ccc}
X' & \longrightarrow & X \\
\downarrow_{\beta'} & & \downarrow_{\beta} \\
Y' & \longrightarrow & Y
\end{array}
\]

in the \( \infty \)-category \( \mathcal{O}^\circ \). We wish to show that \( F(\overline{\beta}) \) is an inert morphism in \( \mathcal{C}^\circ \). Let \( \beta_0 : \langle n \rangle \to \langle k \rangle \) be the image of \( \beta \) in \( N(\mathfrak{Fin}_+) \), and let \( (\beta_0)_! : \mathcal{C}_\circ \to \mathcal{C}_\circ \) denote the induced functor. Then \( F(\overline{\beta}) \) factors as a composition \( F(X) \xrightarrow{\epsilon} F(Y) \), where \( \epsilon \) is inert; we wish to prove that \( \epsilon' \) is an equivalence in \( \mathcal{C}^{\circ}_{(k)} \). Since \( \mathcal{C}^\circ \) is an \( \infty \)-operad, it will suffice to show that \( \rho' \epsilon' \) is an equivalence in \( \mathcal{C}^{\circ}_{(1)} \) for \( 1 \leq j \leq k \). Let

\[
\begin{array}{ccc}
\langle n \rangle & \longrightarrow & \langle m \rangle \\
\downarrow & & \downarrow \\
\langle k' \rangle & \longrightarrow & \langle k \rangle
\end{array}
\]

denote the image of \( \sigma \) in \( N(\mathfrak{Fin}_+) \). This diagram admits a unique extension

\[
\begin{array}{ccc}
\langle n \rangle & \longrightarrow & \langle m \rangle \\
\downarrow & & \downarrow \\
\langle k' \rangle & \longrightarrow & \langle k \rangle \\
\downarrow \chi & & \downarrow \chi' \\
\langle t \rangle & \longrightarrow & \langle 1 \rangle
\end{array}
\]

where the vertical morphisms are inert, the integer \( t \) is equal to 1 and \( \chi' \) is an isomorphism if \( j \) lies in the image of \( \langle n \rangle \to \langle k \rangle \), and \( t = 0 \) otherwise. We can lift this diagram to a commutative triangle

\[
\begin{array}{ccc}
\overline{X} & \xrightarrow{\overline{\beta}} & \overline{Y} \\
\downarrow_{\overline{\pi}} & & \downarrow_{\overline{\pi}'} \\
\overline{Z} & \xrightarrow{\overline{\beta}'} & \overline{\zeta}
\end{array}
\]

of inert morphisms in \( \mathcal{K}_\circ \). If \( F(\overline{\beta}) \) is inert, then we can identify \( F(\overline{\beta}) \) with the composition

\[
F(\overline{X}) \longrightarrow (\rho' \circ \beta_0)_! F(\overline{X}) \xrightarrow{\rho' \epsilon'} F(\overline{Z}),
\]

so that \( \rho' \epsilon' \) is an equivalence in \( \mathcal{C}^{\circ}_{(1)} \) if and only if \( F(\overline{\beta}) \) is inert. We are therefore reduced to proving that \( F(\overline{\beta}) \) and \( F(\overline{\beta}') \) are inert. Replacing \( \overline{\beta} \) by \( \overline{\beta} \) or \( \overline{\beta}' \), we may reduce to the where either \( \chi \) is an isomorphism or \( k' = 0 \).
If $k' = 0$, then we can identify $Y$ with $s(Y)$ and condition $(i)$ guarantees that $F(Y) \to F(Y, 0)$ is an equivalence. It therefore suffices to show that the composite map $F(X) \to F(Y, 0)$ is inert. Since the collection of inert morphisms in $\mathcal{C}^\otimes$ is stable under composition, this follows from $(i')$ and $(ii')$. If $\chi$ is an isomorphism, then we can identify $Y$ with $s(Y)$, and condition $(i)$ guarantees that $F(Y) \to F(Y, 1)$ is an equivalence. It therefore suffices to show that the composite map $F(X) \to F(Y, 1)$ is inert. This follows from $(i')$ and $(ii')$, again because the collection of inert morphisms in $\mathcal{C}^\otimes$ is stable under composition. This completes the verification of condition $(ii)$ and the proof of Proposition 3.4.1.3.

**Proof of Proposition 3.4.1.4.** Let $\mathcal{K} \subseteq \text{Fun}(\Lambda^2_1, \mathcal{O}^\otimes)$ be the full subcategory spanned by those diagrams $X \xrightarrow{\alpha} Y \xrightarrow{\beta} Z$ in $\mathcal{O}^\otimes$ where $\alpha$ and $\beta$ are semi-inert, and let $e_i : \mathcal{K} \to \mathcal{O}^\otimes$ be the map given by evaluation at the vertex $\{i\}$ for $0 \leq i \leq 2$. We will say that a morphism in $\mathcal{K}$ is inert if its image under each $e_i$ is an inert morphism in $\mathcal{O}^\otimes$. If $S$ is a full subcategory of $\mathcal{K}$, we $\mathcal{X}(S)$ denote the simplicial set $(e_0|S)_*(e_2|S)^* \mathcal{C}^\otimes$: that is, $\mathcal{X}(S)$ is a simplicial set equipped with a map $\mathcal{X}(S) \to \mathcal{O}^\otimes$ characterized by the following universal property: for any map of simplicial sets $K \to \mathcal{O}^\otimes \simeq \text{Fun}(\{0\}, \mathcal{O}^\otimes)$, we have a canonical bijection

$$\text{Hom}_{\text{Fun}(\{0\}, \mathcal{O}^\otimes)}(K, \mathcal{X}(S)) = \text{Hom}_{\text{Fun}(\{2\}, \mathcal{O}^\otimes)}(K \times_{\text{Fun}(\{0\}, \mathcal{O}^\otimes)} S, \mathcal{C}^\otimes).$$

We let $\mathcal{X}(S)$ denote the full simplicial subset of $\mathcal{X}(S)$ spanned by those vertices which classify functors carrying inert morphisms in $S$ to inert morphisms in $\mathcal{C}^\otimes$.

Let $\mathcal{K}_1$ denote the full subcategory of $\mathcal{X}(S)$ spanned by those diagrams $X \xrightarrow{\alpha} Y \xrightarrow{\beta} Z$ where $\beta$ is an equivalence, and let $\mathcal{K}_0$ denote the full subcategory of $\mathcal{K}_1$ spanned by those diagrams where $\alpha$ is null. We have a canonical embedding $j : \mathcal{K}_0 \to \mathcal{K}_1$ which carries $\alpha : X \to Y$ to the diagram $X \xrightarrow{\alpha} Y \xleftarrow{\beta} Z$. Let $\mathcal{X}_0 \hookrightarrow \mathcal{X}_1$. Composition with these embeddings gives rise to a commutative diagram

$$\begin{array}{ccc}
\text{Mod}^\otimes(\mathcal{C}) & \xrightarrow{\text{Mod}^\otimes(\mathcal{C})} & \mathcal{X}(\mathcal{K}_1) \\
\downarrow & & \downarrow \\
\text{Alg}_/\mathcal{O}(\mathcal{C}) \times \mathcal{O}^\otimes & \xrightarrow{\text{pAlg}_/\mathcal{O}(\mathcal{C})} & \mathcal{X}(\mathcal{K}_0).
\end{array}$$

The left horizontal maps are categorical equivalences (Remark 3.3.3.7). The right horizontal maps are categorical equivalences because $j$ and $j_0$ admit simplicial homotopy inverses (given by restriction along the inclusion $\Delta^{(0,1)} \subseteq \Lambda^2_1$). Consequently, we are reduced to proving that the diagram

$$\begin{array}{ccc}
\text{Mod}^\otimes(\text{Mod}^\otimes(\mathcal{C})) & \xrightarrow{\text{Mod}^\otimes(\mathcal{C})} & \mathcal{X}(\mathcal{K}_1) \\
\downarrow & & \downarrow \\
\text{Alg}_/\mathcal{O}(\text{Mod}^\otimes(\mathcal{C})) \times \mathcal{O}^\otimes & \xrightarrow{\text{pAlg}_/\mathcal{O}(\mathcal{C})} & \mathcal{X}(\mathcal{K}_0).
\end{array}$$

is a homotopy pullback square.

Let $\mathcal{K}_0$ denote the full subcategory of $\mathcal{K}$ spanned by those diagrams $X \xrightarrow{\alpha} Y \xrightarrow{\beta} Z$ for which $\alpha$ is null, and consider the diagram

$$\begin{array}{ccc}
\text{Mod}^\otimes(\text{Mod}^\otimes(\mathcal{C})) & \xrightarrow{\text{Mod}^\otimes(\mathcal{C})} & \mathcal{X}(\mathcal{K}) \\
\downarrow & & \downarrow \\
\text{Alg}_/\mathcal{O}(\text{Mod}^\otimes(\mathcal{C})) \times \mathcal{O}^\otimes & \xrightarrow{\text{pAlg}_/\mathcal{O}(\mathcal{C})} & \mathcal{X}(\mathcal{K}_0).
\end{array}$$

To complete the proof, it will suffice to show that both of the squares appearing in this diagram are homotopy pullback squares.
We first treat the square on the left. Consider the diagram

\[
\begin{array}{ccc}
\Mod^\odot(A^\odot(X)) & \longrightarrow & \Mod^\odot(A^\odot(Y)) \\
\downarrow & & \downarrow \\
\Alg/\odot(A^\odot(C)) \times \odot & \longrightarrow & \pAlg/\odot(A^\odot(C)) \\
\phi & & \theta \\
\Alg/\odot(A^\odot(Z)) \times \odot & \longrightarrow & \pAlg/\odot(A^\odot(Z)) \\
\end{array}
\]

Since the left horizontal maps are categorical equivalences (Remark 3.3.3.7), it suffices to show that the right square is homotopy Cartesian. Let \( K_2 \) be the full subcategory of \( K \) spanned by those diagrams \( \Delta \twoheadrightarrow Y \to Z \) for which \( \beta \) is null, and let \( K_{02} \) denote the full subcategory of \( K \) spanned by those diagrams where \( \alpha \) and \( \beta \) are both null. The algebra \( A \in \Alg/\odot(\mathcal{C}) \) determines a vertex \( v \) of \( \mathcal{X}(K_2) \) (and therefore, by restriction, a vertex \( v' \) of \( \mathcal{X}(K_{02}) \)). We have a commutative diagram

\[
\begin{array}{ccc}
\overline{\Mod}^\odot(\odot(X)) & \longrightarrow & \mathcal{X}(\mathcal{K}) \\
\downarrow & & \downarrow \theta' \\
\overline{\pAlg}^\odot(\odot(X)) & \longrightarrow & \mathcal{X}(\mathcal{K}_{02}) \\
\phi & & \theta' \\
\end{array}
\]

where the horizontal maps are fiber sequences (where the fibers are taken over the vertices \( v \) and \( v' \), respectively). To show that the left square is a homotopy pullback, it suffices to prove the following:

1. The maps \( \theta \) and \( \theta' \) are categorical fibrations of \( \infty \)-categories.
2. The map \( \phi \) is a categorical equivalence.

To prove (i), we first show that the simplicial sets \( \mathcal{X}(\mathcal{K}), \mathcal{X}(\mathcal{K}_0), \mathcal{X}(\mathcal{K}_2), \) and \( \mathcal{X}(\mathcal{K}_{02}) \) are \( \infty \)-categories. In view of Proposition B.4.5, it will suffice to show that the maps

\[
e_0 : \mathcal{K} \to \odot \quad \quad e_0^0 : \mathcal{K}_0 \to \odot \quad \quad e_0^2 : \mathcal{K}_2 \to \odot \quad \quad e_0^{02} : \mathcal{K}_{02} \to \odot
\]

are flat categorical fibrations. The map \( e_0 \) can be written as a

\[
\mathcal{K} \to^e_0 \mathcal{K}_0 \to^e_0 \mathcal{K}_2 \to^e_0 \mathcal{K}_{02}
\]

where \( e_0' \) is given by restriction along the inclusion \( \Delta^{0,1} \subseteq \Lambda^2_1 \) and \( e_0'' \) is given by evaluation at \( \{0\} \). The map \( e_0'' \) is a flat categorical fibration by virtue of our assumption that \( \odot \) is coherent. The map \( e_0' \) is a pullback of \( e_0'' \), and therefore also flat. Applying Corollary B.3.16, we deduce that \( e_0 \) is flat. The proofs in the other cases are similar: the only additional ingredient that is required is the observation that evaluation at \( 0 \) induces a flat categorical fibration \( \mathcal{K}_0 \to \odot \), which follows from Lemma 3.3.3.3.

To complete the proof of (i), we will show that \( \theta \) and \( \theta' \) are categorical fibrations. We will give the proof for the map \( \theta \); the case of \( \theta' \) is handled similarly. We wish to show that \( \theta \) has the right lifting property with respect to every trivial cofibration \( A \to B \) in \( \Set_{\Delta}/\odot \). Unwinding the definitions, we are required to provide solutions to lifting problems of the form

\[
\begin{array}{ccc}
(A \times \odot \mathcal{K}) \coprod A \times \odot \mathcal{K}_2 & \longrightarrow & \odot \\
\downarrow i & & \downarrow p \\
B \times \odot \mathcal{K} & \longrightarrow & \odot \\
\end{array}
\]
3.4. GENERAL FEATURES OF MODULE $\infty$-CATEGORIES

Since $p$ is a categorical fibration, it suffices to prove that the monomorphism $i$ is a categorical equivalence of simplicial sets. In other words, we need to show that the diagram

$\begin{align*}
A \times_{\mathcal{O}^\otimes} \mathcal{K}_2 & \longrightarrow A \times_{\mathcal{O}^\otimes} \mathcal{K} \\
B \times_{\mathcal{O}^\otimes} \mathcal{K}_2 & \longrightarrow B \times_{\mathcal{O}^\otimes} \mathcal{K}
\end{align*}$

is a homotopy pushout square (with respect to the Joyal model structure). To prove this, it suffices to show that the vertical maps are categorical equivalences. Since $A \to B$ is a categorical equivalence, this follows from Corollary B.3.15 (since the maps $e_0$ and $e_2$ are flat categorical fibrations).

We now prove (ii). Let $\mathcal{K}_3$ denote the full subcategory of $\mathcal{K}$ spanned by those diagrams $X \xrightarrow{\alpha} Y \xrightarrow{\beta} Z$ in $\mathcal{O}^\otimes$ where $Y \in \mathcal{O}_{(0)}^\otimes$. We have a commutative diagram

$\begin{align*}
\mathcal{X}(\mathcal{K}_0) & \xrightarrow{\theta} \mathcal{X}(\mathcal{K}_0^2) \\
\downarrow & \downarrow \\
\mathcal{X}(\mathcal{K}_3).
\end{align*}$

Consequently, to show that $\theta$ is a categorical equivalence, it suffices to show that the diagonal maps in this diagram are categorical equivalences. We will show that $\mathcal{X}(\mathcal{K}_0) \to \mathcal{X}(\mathcal{K}_3)$ is a categorical equivalence; the proof for $\mathcal{X}(\mathcal{K}_0^2) \to \mathcal{X}(\mathcal{K}_3)$ is similar. Let $X \xrightarrow{\alpha} Y \xrightarrow{\beta} Z$ be an object $K \in \mathcal{K}_0$, and choose a morphism $\gamma : Y \to Y_0$ where $Y_0 \in \mathcal{O}^\otimes$. Since $\beta$ is null, it factors through $\gamma$, and we obtain a commutative diagram

$\begin{align*}
X & \xrightarrow{\alpha} Y \xrightarrow{\beta} Z \\
\downarrow & \downarrow & \downarrow & \downarrow \\
X & \xrightarrow{\gamma \circ \alpha} Y_0 \xrightarrow{id} Z.
\end{align*}$

We can interpret this diagram as a morphism $\gamma : K \to K_0$ in $\mathcal{K}_0$. It is not difficult to see that this $\gamma$ exhibits $K_0$ as a $\mathcal{K}_3$-localization of $K$. Consequently, the construction $K \mapsto K_0$ can be made into a functor $L : \mathcal{K}_0 \to \mathcal{K}_3$, equipped with a natural transformation $t : \text{id} \to L$. Without loss of generality, we can assume that $L$ and $t$ commute with the evaluation maps $e_0$ and $e_2$. Composition with $L$ determines a map $\mathcal{X}(\mathcal{K}_3) \to \mathcal{X}(\mathcal{K}_0)$, and the transformation $t$ exhibits this map as a homotopy inverse to the restriction map $\mathcal{X}(\mathcal{K}_0) \to \mathcal{X}(\mathcal{K}_3)$. This completes the proof of (ii).

It remains to show that the diagram

$\begin{align*}
\mathcal{X}(\mathcal{K}) & \longrightarrow \mathcal{X}(\mathcal{K}_1) \\
\downarrow & \downarrow \\
\mathcal{X}(\mathcal{K}_0) & \longrightarrow \mathcal{X}(\mathcal{K}_{01})
\end{align*}$

is a homotopy pullback square. We first claim that $\psi$ is a categorical equivalence of $\infty$-categories. The proof is similar to the proof of (i): the only nontrivial point is to verify that the restriction maps

$e_0^1 : \mathcal{K}_1 \to \mathcal{O}^\otimes \quad e_0^{01} : \mathcal{K}_{01} \to \mathcal{O}^\otimes$

are flat categorical fibrations. We will give the proof for $e_0^1$; the proof for $e_0^{01}$ is similar. We can write $e_0^1$ as a composition $\mathcal{K}_1 \to \mathcal{K}_0 \to \mathcal{O}^\otimes$, where the second map is a flat categorical fibration by virtue of our assumption that $\mathcal{O}^\otimes$ is coherent. The first map is a pullback of the restriction map $\text{Fun}^0(\Delta^1, \mathcal{O}^\otimes) \text{Fun}(\{0\}, \mathcal{O}^\otimes)$, where
Fun⁰(Δ¹, O⊗) denotes the full subcategory of Fun(Δ¹, O⊗) spanned by the equivalences in O⊗, and therefore a trivial Kan fibration (and, in particular, a flat categorical fibration). Applying Corollary B.3.16, we conclude that e₀ is a flat categorical fibration, as desired.

Since ψ is a categorical fibration of ∞-categories and X(X₀) is an ∞-category, we have a homotopy pullback diagram

\[
\begin{array}{ccc}
X(X₀) ×_{X(X₀)} X(X₁) & \longrightarrow & X(X₁) \\
\downarrow & & \downarrow \\
X(X₀) & \longrightarrow & X(X₀₁).
\end{array}
\]

To complete the proof, it will suffice to show that the restriction map τ : X(K) → X(X₀) ×_{X(X₀)} X(X₁) is a categorical equivalence. We will show that τ is a trivial Kan fibration. Note that the evaluation map e₀ : K → O⊗ is a Cartesian fibration; moreover, if K → K’ is an e₀-Cartesian morphism in K and K’ ∈ X₀ 1, then K ∈ X₀ 1. It follows that e₀ restricts to a Cartesian fibration X₀ 1 → O⊗.

In view of Lemma 3.4.2.2, the map τ will be a trivial Kan fibration provided that the following pair of assertions holds:

(a) Let F ∈ X(K) be an object lying over X ∈ O⊗ which we will identify with a functor \{X\} ×_{O⊗} K → C⊗. Let F₀ = F(\{X\} ×_{O⊗} (X₀ × X₁)), and assume that F₀ ∈ X(X₀) ×_{X(X₀)} X(X₁). Then F ∈ X(K) if and only if F is a p-right Kan extension of F₀.

(b) Let F₀ ∈ X(X₀) ×_{X(X₀)} X(X₁). Then there exists an extension F of F₀ which satisfies the equivalent conditions of (a).

To prove these assertions, let us consider an object X ∈ O⊗ and an object F₀ ∈ X(X₀) ×_{X(X₀)} X(X₁) lying over X. Let D = \{X\} ×_{O⊗} K denote the ∞-category of diagrams X \xrightarrow{α} Y \xrightarrow{β} Z in O⊗, and define full subcategories D₀, D₁, and D₀₁ similarly. Let K be an object of D, corresponding to a decomposition X ≃ X₀ ⊕ X₁ ⊕ X₂ and a diagram

\[
X₀ ⊕ X₁ ⊕ X₂ \rightarrow X₀ ⊕ X₁ ⊕ Y₀ ⊕ Y₁ \rightarrow X₀ ⊕ Y₀ ⊕ Z
\]

diagram of semi-inert morphisms in O⊗. We have a commutative diagram

\[
\begin{array}{ccc}
K & \longrightarrow & K₁ \\
\downarrow & & \downarrow \\
K₀ & \longrightarrow & K₀₁
\end{array}
\]

in D, where K₀ ∈ D₀ represents the diagram X₀ ⊕ X₁ ⊕ X₂ → Y₀ ⊕ Y₁ → Y₀ ⊕ Z, K₁ ∈ D₁ represents the diagram X₀ ⊕ X₁ ⊕ X₂ → X₀ ⊕ Y₀ ⊕ Z ≃ X₀ ⊕ Y₀ ⊕ Z, and K₀₁ ∈ D₀₁ represents the diagram X₀ ⊕ X₁ ⊕ X₂ → Y₀ ⊕ Y₁ → Y₀ ⊕ Z. This diagram exhibits K₀, K₁, and K₀₁ as initial objects of (D₀)₁, (D₁)₁, and (D₀₁)₁, respectively. Applying Theorem T.4.1.3.1, we conclude that the induced map Λ₂ → (D₀ 1, D₁ 1, and D₀₁₁) is right cofinal, so that an extension F of F₀ is a p-right Kan extension of F₀ at K if and only if the diagram

\[
\begin{array}{ccc}
F(K) & \longrightarrow & F₀(K₁) \\
\downarrow & & \downarrow \\
F₀(K₀) & \longrightarrow & F₀(K₀₁)
\end{array}
\]

is a p-limit diagram in C⊗. Choose equivalences F₀(K₀) = y₀ ⊕ z, F₀(K₁) = x₀ ⊕ y₀ ⊕ z’, and F₀(K₀₁) = y₀ ⊕ z”.

If we let K’ ∈ D denote the object corresponding to the diagram X₀ ⊕ X₁ ⊕ X₂ → Y₀ ≃ Y₀ and apply our
assumption that \( F_0|D_0 \in \mathcal{X}(\mathcal{K}_0) \) to the commutative diagram

\[
\begin{array}{ccc}
K_0 & \rightarrow & K_{01} \\
\downarrow & & \downarrow \\
K' & \rightarrow & K_{01}
\end{array}
\]

then we deduce that \( F_0(K_0) \rightarrow F_0(K_{01}) \) induces an equivalence \( y_0 \simeq y_0' \). Similarly, the assumption that \( F_0|D_1 \in \mathcal{X}(\mathcal{K}_1) \) guarantees that \( F_0(K_1) \rightarrow F_0(K_{01}) \) is inert, so that \( y_0' \simeq y_0'' \). It then follows from Lemma 3.4.3.15 that the diagram \( F_0(K_1) \rightarrow F_0(K_{01}) \leftarrow F_0(K_0) \) admits a \( p \)-limit (covering the evident map \( \Delta^1 \times \Delta^1 \rightarrow \emptyset \)), so that \( F_0|\left( \mathcal{D}_0 \coprod_{\mathcal{D}_1} \mathcal{D}_1 \right)_{K/} \) also admits a \( p \)-limit (covering the map \( \mathcal{D}_0 \coprod_{\mathcal{D}_1} \mathcal{D}_1 \rightarrow \emptyset \)); assertion \((b)\) now follows from Lemma T.4.3.2.13. Moreover, the criterion of Lemma 3.4.3.15 gives the following version of \((a)\):

\((a')\) An extension \( F \in \Xi(\mathcal{K}) \) of \( F_0 \) is a \( p \)-right Kan extension of \( F_0 \) at \( K \) if and only if, for every object \( K \in \mathcal{D} \) as above, the maps \( F(K) \to F_0(K_0) \) and \( F(K) \to F_0(K_1) \) induce an equivalence \( F(K) \simeq x_0' \oplus y_0 \oplus z \) in \( \mathcal{E} \).

To complete the proof, it will suffice to show that the criterion of \((a')\) holds if and only if \( F \in \Xi(\mathcal{K}) \). We first prove the “if” direction. Fix \( K \in \mathcal{D} \), so that we have an equivalence \( F(K) \simeq x_0' \oplus y_0 \oplus z \). Since \( K 
rightarrow K_0 \) is inert, the assumption that \( F \in \Xi(\mathcal{K}) \) implies that \( F(K) \to F(K_0) \) is inert, so that \( y_0 \simeq y_0' \) and \( z \simeq z \). Let \( K'' \in \mathcal{D} \) be the diagram \( X_0 \oplus X_1 \oplus X_2 \to Y_0 \simeq Y_0 \), so that we have a commutative diagram

\[
\begin{array}{ccc}
K & \rightarrow & K_1 \\
\downarrow & & \downarrow \\
K'' & \rightarrow & K_{01}
\end{array}
\]

in which the diagonal maps are inert. It follows that the morphisms \( F(K) \to F(K'') \leftarrow F(K_1) \) are inert, so that the map \( F(K) \to F(K_1) \) induces an equivalence \( y_0 \simeq y_0' \).

We now prove the “only if” direction. Assume that \( F \in \Xi(\mathcal{K}) \) is an extension of \( F_0 \) which satisfies the criterion given in \((a')\); we will show that \( F \) carries inert morphisms in \( \mathcal{D} \subseteq \mathcal{K} \) to inert morphisms in \( \mathcal{E} \). Let \( K \to L \) be an inert morphism in \( \mathcal{D} \), where \( K \) is as above and \( L \) corresponds to a diagram \( X \to Y' \to Z' \); we wish to prove that the induced map \( F(K) \to F(L) \) is inert. Let \( (n) \) denote the image of \( Z' \) in \( N(\mathcal{F}in_\mathcal{K}) \), and choose inert morphisms \( Z' \to Z_i' \) lying over \( \rho^i : (n) \to (1) \) for \( 1 \leq i \leq n \). Each of the induced maps \( Y' \to Z_i \) factors as a composition \( Y' \to Y_i' \to Z_i \), where the first map is inert and the second is active. Let \( L_i \in \mathcal{D} \) denote the diagram \( X \to Y_i' \to Z_i' \). To show that \( F(K) \to F(L) \) is inert, it will suffice to show that the maps \( F(K) \to F(L_i) \leftrightarrow F(L) \) are inert for \( 1 \leq i \leq n \). Replacing \( L \) by \( L_i \) (and possibly replacing \( K \) by \( L \)), we may reduce to the case where \( n = 1 \) and the map \( Y' \to Z' \) is active. There are two cases to consider:

- The map \( Y' \to Z' \) is an equivalence. In this case, the map \( K \to L \) factors as a composition \( K \to K_1 \to L \). Since \( F_0|D_1 \in \mathcal{X}(\mathcal{K}_1) \), the map \( F(K_1) \to F(L) \) is inert. Consequently, the assertion that \( F(K) \to F(K_1) \) is inert follows our assumption that \( F(K) \to F(K_1) \) induces an equivalence \( y_0 \to y_0' \).

- The map \( Y' \to Z' \) is null (so that \( Y' \in \emptyset_{(0)} \)). In this case, the map \( K \to L \) factors as a composition \( K \to K_0 \to L \). Assumption \((a')\) guarantees that \( F(K) \to F(K_0) \) is inert, and the assumption that \( F_0|X_0 \in \mathcal{X}(\mathcal{K}_0) \) guarantees that \( F(K_0) \to F(L) \) is inert.

\[\square\]
3.4.2 Modules over Trivial Algebras

Let \( \mathcal{C} \) be a symmetric monoidal category. Let \( 1 \) denote the unit object of \( \mathcal{C} \), so that for every object \( C \in \mathcal{C} \) we have a canonical isomorphism \( u_C : 1 \otimes C \to C \). In particular, \( u_1 \) gives a multiplication \( 1 \otimes 1 \to 1 \) which exhibits \( 1 \) as a commutative algebra object of \( \mathcal{C} \). Moreover, for every object \( C \in \mathcal{C} \), \( u_C \) exhibits \( C \) as a module over the commutative algebra \( 1 \). In fact, this construction determines a functor \( \mathcal{C} \to \text{Mod}_1(\mathcal{C}) \), which is homotopy inverse to the forgetful functor \( \theta : \text{Mod}_1(\mathcal{C}) \to \mathcal{C} \), as a module over the commutative algebra \( 1 \).

Our goal in this section is to prove the following result, which can be regarded as an \( \infty \)-categorical generalization of the above discussion:

**Proposition 3.4.2.1.** Let \( p : \mathcal{O}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads and assume that \( \mathcal{O}^\otimes \) is coherent. Let \( A \) be a trivial \( \mathcal{O} \)-algebra object of \( \mathcal{C} \). Then the forgetful functor \( \theta : \text{Mod}_A^\mathcal{O}(\mathcal{C})^\otimes \to \mathcal{C}^\otimes \) is an equivalence of \( \infty \)-operads.

The of Proposition 3.4.2.1 will require a few preliminary results.

**Lemma 3.4.2.2.** Let \( p : X \to S \) be an inner fibration of simplicial sets. Let \( X^0 \) be a full simplicial subset of \( X \), and assume that the restriction map \( p^0 = p|X^0 \) is a coCartesian fibration. Let \( q : Y \to Z \) be a categorical fibration of simplicial sets. Define a simplicial sets \( A \) and \( B \) equipped with maps \( A, B \to S \) so that the following universal property is satisfied: for every map of simplicial sets \( K \to S \), we have bijections

\[
\text{Hom}_{(\Delta, \mathcal{S})/S}(K, A) \simeq \text{Fun}(X \times_S K, Y)
\]

\[
\text{Hom}_{(\Delta, \mathcal{S})/S}(K, B) \simeq \text{Fun}(X^0 \times_S K, Y) \times \text{Fun}(X^0 \times_S K, Z) \times \text{Fun}(X \times_S K, Z).
\]

Let \( \phi : A \to B \) be the restriction map. Let \( A' \) denote the full simplicial subset of \( A \) spanned by those vertices corresponding to maps \( f : X_s \to Y \) such that \( f \) is a \( q \)-left Kan extension of \( f|X^0 \), and let \( B' \) denote the full simplicial subset of \( B \) spanned by those vertices of the form \( \phi(f) \) where \( f \in A' \). Then \( \phi \) induces a trivial Kan fibration \( \phi' : A' \to B' \).

**Proof.** For every map of simplicial sets \( T \to S \), let \( F(T) = \text{Map}_S(T, A') \) and let \( G(T) = \text{Map}_S(T, B') \). If \( T_0 \subseteq T \) is a simplicial subset, we have a restriction map \( \theta_{T_0,T} : F(T) \to G(T) \times_{G(T_0)} F(T_0) \). To prove that \( \phi' \) is a trivial Kan fibration, it will suffice to show that \( \theta_{T_0,T} \) is surjective on vertices whenever \( T = \Delta^n \) and \( T_0 = \partial \Delta^n \). We will complete the proof by showing that \( \theta_{T_0,T} \) is a trivial Kan fibration whenever \( T \) has only finitely many simplices.

The proof proceeds by induction on the dimension of \( T \) (if \( T \) is empty, the result is trivial). Assume first that \( T = \Delta^n \). If \( T_0 = T \) there is nothing to prove. Otherwise, we may assume that \( T_0 \) has dimension smaller than \( n \). Using the fact that \( q \) is a categorical fibration, we deduce that \( \theta_{T_0,T} \) is a categorical fibration. It therefore suffices to show that \( \theta_{T_0,T} \) is a categorical equivalence. We have a commutative diagram

\[
\begin{array}{ccc}
F(T) & \xrightarrow{\psi} & G(T) \\
\downarrow{\psi'} & & \downarrow{\psi'} \\
G(T) & \xrightarrow{\psi} & G(T) \times_{G(T_0)} F(T_0)
\end{array}
\]

The inductive hypothesis (applied to the inclusion \( \emptyset \subseteq T_0 \)) guarantees that \( \psi' \) is a trivial Kan fibration. It will therefore suffice to show that \( \psi \) is a trivial Kan fibration. In view of Proposition T.4.3.2.15, it will suffice to prove the following assertions:

(a) Let \( F : \Delta^n \times_S X \to Y \) be a functor. Then \( F \) is a \( q \)-left Kan extension of \( F|(\Delta^n \times_S X^0) \) if and only if \( F|((i) \times_S X) \) is a \( q \)-left Kan extension of \( F|((i) \times_S X^0) \) for \( 0 \leq i \leq n \).
(b) Suppose we are given a commutative diagram

\[
\begin{array}{ccc}
\Delta^n \times_S X^0 & \xrightarrow{f} & Y \\
\downarrow F & & \downarrow q \\
\Delta^n \times_S X & \xrightarrow{g} & Z
\end{array}
\]

such that for \(0 \leq i \leq n\), there exists a \(q\)-left Kan extension \(F_i : \{i\} \times_S X \to Y\) of \(f|\{i\} \times_S X^0\) which is compatible with \(g\). Then there exists a dotted arrow \(F\) as indicated satisfying the condition described in (a).

Assertion (a) follows from the observation that for \(x \in \{i\} \times_S X\), the assumption that \(p^0\) is a coCartesian fibration guarantees that \(X^0 \times_X (\{i\} \times_S X)/x\) is left cofinal in \(X^0 \times_X (\Delta^n \times_S X)/x\). Assertion (b) follows from the same observation together with Lemma T.4.3.2.13.

We now complete the proof by considering the case where \(T\) is not a simplex. We use induction on the number \(k\) of simplices of \(T'\) which do not belong to \(T\). If \(k = 0\), then \(T' = T\) and there is nothing to prove. If \(k = 1\), then there is a pushout diagram

\[
\begin{array}{ccc}
\partial \Delta^n & \xrightarrow{} & T_0 \\
\downarrow & & \downarrow \\
\Delta^n & \xrightarrow{} & T.
\end{array}
\]

It follows that \(\theta_{T_0,T}\) is a pullback of the map \(\theta_{\partial \Delta^n, \Delta^n}\), and we are reduced to the case where \(T\) is a simplex. If \(k > 1\), then we have nontrivial inclusions \(T_0 \subset T_1 \subset T\). Using the inductive hypothesis, we conclude that \(\theta_{T_1,T}\) and \(\theta_{T_0,T_1}\) are trivial Kan fibrations. The desired result follows from the observation that \(\theta_{T_0,T}\) can be obtained by composing \(\theta_{T_1,T}\) with a pullback of the morphism \(\theta_{T_0,T_1}\).

Lemma 3.4.2.3. Let \(p : \mathcal{C}^\otimes \to \mathcal{O}^\otimes\) be a fibration of \(\infty\)-operads. Assume that \(\mathcal{O}^\otimes\) is unital and that \(p\) has unit objects. Let \(C \in \mathcal{C}^\otimes\) and let \(\alpha : p(C) \to Y\) be a semi-inert morphism in \(\mathcal{O}^\otimes\). Then \(\alpha\) can be lifted to a \(p\)-coCartesian morphism \(\overline{\alpha} : C \to \overline{Y}\) in \(\mathcal{C}^\otimes\).

Proof. The map \(\alpha\) can be factored as the composition of an inert morphism and an active morphism. We may therefore reduce to the case where \(\alpha\) is either active or inert. If \(\alpha\) is inert, we can choose \(\overline{\alpha}\) to be an inert morphism lifting \(\alpha\). Assume therefore that \(\alpha\) is active. Write \(C \simeq C_1 \oplus \ldots \oplus C_m\) (using the notation of Remark 2.2.4.6), and write \(Y = p(C_1) \oplus \ldots \oplus p(C_m) \oplus Y_1 \oplus \ldots \oplus Y_n\). Since \(\mathcal{O}^\otimes\) is unital, we may assume that \(\alpha\) has the form \(\id_{p(C_1)} \oplus \ldots \oplus \id_{p(C_m)} \oplus \alpha_1 \oplus \ldots \oplus \alpha_n\), where each \(\alpha_i : 0 \to Y_i\) is a morphism with \(0 \in \mathcal{O}^{\otimes}(0)\). Since \(p\) has units, we can lift each \(\alpha_i\) to a morphism \(\overline{\alpha}_i : \overline{Y}_i \to \overline{Y}_i\) which exhibits \(\overline{Y}_i\) as a \(p\)-unit. Let \(\overline{\alpha} = \id_{\overline{C}_1} \oplus \ldots \oplus \id_{\overline{C}_m} \oplus \overline{\alpha}_1 \oplus \ldots \oplus \overline{\alpha}_n\). It follows from Proposition 3.1.1.10 that \(\overline{\alpha}\) is \(p\)-coCartesian.

Proof of Proposition 3.4.2.1. We may assume that \(p\) has unit objects (otherwise the assertion is vacuous). Let \(\phi : \mathcal{O}^\otimes \times \Alg_{/ \mathcal{O}}(\mathcal{E}) \rightarrow \Alg_{/ \mathcal{O}}(\mathcal{E})\) be the equivalence of Remark 3.3.3.7, and let \(\mathcal{X} \subseteq \Alg_{/ \mathcal{O}}(\mathcal{E})\) denote the essential image of the full subcategory spanned by those pairs \((X, A)\) where \(A\) is trivial. Let \(\mathcal{X}'\) denote the fiber product \(\mathcal{X} \times_{\Alg_{/ \mathcal{O}}(\mathcal{E})} \Mod_{\mathcal{O}^\otimes}(\mathcal{E})\). Since Proposition 3.2.1.8 implies that trivial \(\mathcal{O}\)-algebras form a contractible Kan complex, the inclusion \(\Mod_{\mathcal{O}^\otimes}(\mathcal{E}) \subseteq \mathcal{X}'\) is a categorical equivalence. It will therefore suffice to show that composition with the diagonal map \(\delta : \mathcal{O}^\otimes \to \mathcal{X}_0\) induces a categorical equivalence \(\mathcal{X}' \to \mathcal{E}^\otimes\).

Let \(\mathcal{X}_0\) denote the essential image of \(\delta\), and define a simplicial set \(\mathcal{Y}\) equipped with a map \(\mathcal{Y} \to \mathcal{O}^\otimes\) so that the following universal property is satisfied: for every map of simplicial sets \(K \to \mathcal{O}^\otimes\), we have a canonical bijection

\[
\Hom_{(\Set_{\Delta})/ \mathcal{O}^\otimes}(K, \mathcal{Y}) \simeq \Hom_{(\Set_{\Delta})/ \mathcal{O}^\otimes}(K \times_{\Fun((0), \mathcal{O}^\otimes)} \mathcal{X}_0, \mathcal{E}^\otimes).
\]

Since \(\delta\) is fully faithful, it induces a categorical equivalence \(\mathcal{O}^\otimes \to \mathcal{X}_0\). It follows that the canonical map \(\mathcal{Y} \to \mathcal{E}^\otimes\) is a categorical equivalence.
We have a commutative diagram

\[
\begin{array}{ccc}
X' & \xrightarrow{\theta'} & Y \\
& \searrow & \\
& \mathcal{E}^\otimes &
\end{array}
\]

Consequently, it will suffice to show that \(\theta'\) is a categorical equivalence. We will prove that \(\theta'\) is a trivial Kan fibration.

Define a simplicial set \(\mathcal{D}\) equipped with a map \(\mathcal{D} \to \mathcal{O}^\otimes\) so that the following universal property is satisfied: for every map of simplicial sets \(K \to \mathcal{O}^\otimes\), we have a canonical bijection

\[
\text{Hom}(\text{Set}_\Delta)_{/\mathcal{O}^\otimes}(K, \mathcal{D}) \simeq \text{Hom}(\text{Set}_\Delta)_{/\mathcal{O}^\otimes}(K \times \text{Fun}(\{0\}, \mathcal{O}^\otimes) \mathcal{K}_0, \mathcal{O}^\otimes).
\]

For each \(X \in \mathcal{O}^\otimes\), let \(\mathcal{E}_X\) denote the full subcategory of \((\mathcal{O}^\otimes)^X/\) spanned by the semi-inert morphisms \(X \to Y\) in \(\mathcal{O}^\otimes\), and let \(\mathcal{E}^1_X\) denote the full subcategory of \((\mathcal{O}^\otimes)^X/\) spanned by the equivalences \(X \to Y\) in \(\mathcal{O}^\otimes\). An object of \(\mathcal{D}\) can be identified with a pair \((X, F)\), where \(X \in \mathcal{O}^\otimes\) and \(F : A_X \to \mathcal{E}^\otimes\) is a functor. We will prove the following:

(a) The full subcategory \(\mathcal{X}' \subseteq \mathcal{D}\) is spanned by those pairs \((X, F)\) where \(F : \mathcal{E}_X \to \mathcal{E}^\otimes\) is a \(q\)-left Kan extension of \(F|\mathcal{E}^1_X\).

(b) For every \(X \in \mathcal{O}^\otimes\) and every functor \(f \in \text{Fun}_{\mathcal{O}^\otimes}(\mathcal{E}^1_X, \mathcal{E}^\otimes)\), there exists a \(q\)-left Kan extension \(F \in \text{Fun}_{\mathcal{O}^\otimes}(\mathcal{E}_X, \mathcal{E}^\otimes)\) of \(f\).

Assuming that (a) and (b) are satisfied, the fact that the restriction functor \(\mathcal{X}' \to \mathcal{Y}\) is a trivial Kan fibration will follow immediately from Lemma 3.4.2.2.

Note that for \(X \in \mathcal{O}^\otimes\), we can identify \(\mathcal{E}^1_X\) with the full subcategory of \(\mathcal{E}_X\) spanned by the initial objects. Consequently, a functor \(f \in \text{Fun}_{\mathcal{O}^\otimes}(\mathcal{E}^1_X, \mathcal{E}^\otimes)\) as in (b) is determined up to equivalence by \(f(\text{id}_X) \in \mathcal{E}^1_X\).

Using Lemma T.4.3.2.13, we deduce that \(f\) admits a \(q\)-left Kan extension \(F \in \text{Fun}_{\mathcal{O}^\otimes}(\mathcal{E}_X, \mathcal{E}^\otimes)\) if and only if every semi-inert morphism \(X \to Y\) in \(\mathcal{O}^\otimes\) can be lifted to a \(q\)-coCartesian morphism \(f(\text{id}_X) \to \mathcal{Y}\) in \(\mathcal{E}^\otimes\). Assertion (b) now follows from Lemma 3.4.2.3.

We now prove (a). Suppose first that \(F\) is a \(q\)-left Kan extension of \(F|\mathcal{E}^1_X\). The proof of (b) shows that \(F(u)\) is \(q\)-coCartesian for every morphism \(u : Y \to Z\) in \(\mathcal{E}_X\) such that \(Y\) is an initial object of \(\mathcal{E}_X\). Since every morphism \(u\) in \(\mathcal{E}_X\) fits into a commutative diagram

\[
\begin{array}{ccc}
Y & \xrightarrow{u} & Z \\
\text{id}_X & \searrow & \\
& 0_X &
\end{array}
\]

Proposition T.2.4.1.7 guarantees that \(F\) carries every morphism in \(\mathcal{E}_X\) to a \(q\)-coCartesian morphism in \(\mathcal{E}^\otimes\). In particular, \(F\) carries inert morphisms in \(\mathcal{E}_X\) to inert morphisms in \(\mathcal{E}^\otimes\), and therefore belongs to \(\text{Mod}^{\mathcal{O}^\otimes}_{\mathcal{E}^\otimes}(\mathcal{E}^\otimes) \times_{\mathcal{O}^\otimes} \{X\}\). Let \(\mathcal{E}_X^0\) denote the full subcategory of \(\mathcal{E}_X\) spanned by the null morphisms \(X \to Y\) in \(\mathcal{O}^\otimes\), and let \(s : \mathcal{O}^\otimes \to \mathcal{E}_X^0\) denote a section to the trivial Kan fibration \(\mathcal{E}_X^0 \to \mathcal{O}^\otimes\). To prove that \(F \in \mathcal{X}'\), it suffices to show that the composition

\[
\mathcal{O}^\otimes \overset{s}{\to} \mathcal{E}_X^0 \subseteq \mathcal{E}_X \overset{F}{\to} \mathcal{E}^\otimes
\]

is a trivial \(\mathcal{O}\)-algebra. Since this composition carries every morphism in \(\mathcal{O}^\otimes\) to a \(q\)-coCartesian morphism in \(\mathcal{E}^\otimes\), it is an \(\mathcal{O}\)-algebra: the triviality now follows from Remark 3.2.1.4.

To complete the proof of (a), let us suppose that \(F \in \mathcal{X}'\); we wish to show that \(F\) is a \(q\)-left Kan extension of \(f = F|\mathcal{E}^1_X\). Using (b), we deduce that \(f\) admits a \(q\)-left Kan extension \(F' \in \text{Fun}_{\mathcal{O}^\otimes}(\mathcal{E}_X, \mathcal{E}^\otimes)\). Let \(\alpha : F' \to F\) be a natural transformation which is the identity on \(f\); we wish to prove that \(\alpha\) is an equivalence. Fix an object \(\mathcal{Y} \in \mathcal{E}_X\), corresponding to a semi-inert morphism \(X \to Y\) in \(\mathcal{O}^\otimes\). Let \(\langle n \rangle \in N(\text{Fin}_*)\) denote
the image of \( Y \), and choose inert morphisms \( Y \to Y_i \) lifting the maps \( \rho^i : \langle n \rangle \to \langle 1 \rangle \). Let \( \overline{Y}_i \) denote the composition of \( \overline{Y} \) with the map \( Y \to Y_i \) for \( 1 \leq i \leq n \). Since \( F \) and \( F' \) both preserve inert morphisms and \( \mathcal{C}^\otimes \) is an \( \infty \)-operad, it suffices to prove that \( \alpha_{\overline{Y}_i} : F'(\overline{Y}_i) \to F(\overline{Y}_i) \) is an equivalence for \( 1 \leq i \leq n \). We may therefore replace \( Y \) by \( Y_i \) and reduce to the case where \( Y \in \mathcal{O} \). In this case, the semi-inert morphism \( \overline{Y} \) is either null or inert.

If the map \( \overline{Y} : X \to Y \) is null, then \( \overline{Y} \in \mathcal{C}^\otimes_X \). Since \( F \circ s \) and \( F' \circ s \) both determine trivial \( \mathcal{O} \)-algebra objects, the induced natural transformation \( F' \circ s \to F \circ s \) is an equivalence (Proposition 3.2.1.8). It follows that the natural transformation \( F'|\mathcal{C}^\otimes_X \to F|\mathcal{C}^\otimes_X \) is an equivalence, so that \( F'(\overline{Y}) \simeq F(\overline{Y}) \).

If the map \( \overline{Y} : X \to Y \) is inert, then we have an inert morphism \( u : \text{id}_X \to \overline{Y} \) in \( \mathcal{E}_X \). Since \( F \) and \( F' \) both preserve inert morphisms, it suffices to show that the map \( F'(\text{id}_X) \to F(\text{id}_X) \) is an equivalence. This is clear, since \( \text{id}_X \in \mathcal{E}_X^1 \).

### 3.4.3 Limits of Modules

Let \( \mathcal{C} \) be a symmetric monoidal category and let \( A \) be a commutative algebra object of \( \mathcal{C} \). Suppose we are given a diagram \( \{ M_\alpha \} \) in the category of \( \mathcal{A} \)-modules, and let \( M = \lim_{\alpha} M_\alpha \) be the limit of this diagram in the category \( \mathcal{C} \). The collection of maps

\[
A \otimes M \to A \otimes M_\alpha \to M_\alpha
\]

determines a map \( A \otimes M \to M \), which endows \( M \) with the structure of an \( \mathcal{A} \)-module. Moreover, we can regard \( M \) also as a limit of the diagram \( \{ M_\alpha \} \) in the category of \( \mathcal{A} \)-modules.

Our goal in this section is to prove an analogous result in the \( \infty \)-categorical setting, for algebras over an arbitrary coherent \( \infty \)-operad. We can state our main result as follows:

**Theorem 3.4.3.1.** Let \( q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads, where \( \mathcal{O}^\otimes \) is coherent. Suppose we are given a commutative diagram

\[
\begin{array}{ccc}
K & \xrightarrow{p} & \text{Mod}_{\mathcal{O}}^{\otimes}(\mathcal{C})^\otimes \\
\downarrow & & \downarrow \psi \\
K^\otimes & \xrightarrow{p} & \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \times \mathcal{O}^\otimes
\end{array}
\]

such that the underlying map \( K^\otimes \to \mathcal{O}^\otimes \) takes some constant value \( X \in \mathcal{O} \), and the lifting problem

\[
\begin{array}{ccc}
K & \xrightarrow{p'} & \mathcal{C}^\otimes \\
\downarrow & & \downarrow q \\
K^\otimes & \xrightarrow{p} & \mathcal{O}^\otimes
\end{array}
\]

admits a solution, where \( p \) is a \( q \)-limit diagram. Then:

1. There exists a map \( \overline{p} \) making the original diagram commute, such that \( \delta \circ \overline{p} \) is a \( q \)-limit diagram in \( \mathcal{C}^\otimes \) (here \( \delta : \text{Mod}_{\mathcal{O}}^{\otimes}(\mathcal{C})^\otimes \to \mathcal{C}^\otimes \) denotes the map given by composition with the diagonal embedding \( \mathcal{O}^\otimes \to \mathcal{K}_\mathcal{O} \subseteq \text{Fun}(\Delta^1, \mathcal{O}^\otimes) \).

2. Let \( \overline{p} \) be an arbitrary map making the above diagram commute. Then \( \overline{p} \) is a \( \psi \)-limit diagram if and only if \( \delta \circ \overline{p} \) is a \( q \)-limit diagram.

Theorem 3.4.3.1 has a number of consequences. First, it allows us to describe limits in an \( \infty \)-category of modules:

**Corollary 3.4.3.2.** Let \( q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads, where \( \mathcal{O}^\otimes \) is coherent, and let \( A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \) and \( X \in \mathcal{O} \). Suppose we are given a diagram \( p : K \to \text{Mod}_{\mathcal{O}}^{\otimes}(\mathcal{C})^\otimes_X \) such that the induced map \( p' : K \to \mathcal{C}^\otimes_X \) can be extended to a \( q \)-limit diagram \( \overline{p} : K^\otimes \to \mathcal{C}^\otimes_X \). Then:
(1) There exists an extension $\rho: K^\circ \to \text{Mod}_A^O(\mathcal{C})^\circ_X$ of $p$ such that the induced map $K^\circ \to \mathcal{C}^\circ$ is a $q$-limit diagram.

(2) Let $\rho: K^\circ \to \text{Mod}_A^O(\mathcal{C})^\circ_X$ be an arbitrary extension of $p$. Then $\rho$ is a limit diagram if and only if it induces a $q$-limit diagram $K^\circ \to \mathcal{C}^\circ$.

We can also use Theorem 3.4.3.1 to describe the relationships between the $\infty$-categories $\text{Mod}_A^O(\mathcal{C})$ as the algebra $A$ varies.

**Corollary 3.4.3.3.** Let $q: \mathcal{C}^\circ \to \mathcal{O}^\circ$ be a fibration of $\infty$-operads, where $\mathcal{O}^\circ$ is coherent. Then for each $X \in \mathcal{O}$, the functor $\phi: \text{Mod}^O(\mathcal{C})^\circ_X \to \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ is a Cartesian fibration. Moreover, a morphism $f$ in $\text{Mod}^O(\mathcal{C})_X$ is $\phi$-Cartesian if and only if its image in $\mathcal{C}^\circ_X$ is an equivalence.

More informally: if we are given a morphism $A \to B$ in $\text{Alg}_{/\mathcal{O}}(\mathcal{C})$, then there is an evident forgetful functor from $B$-modules to $A$-modules, which does not change the underlying object of $\mathcal{C}$.

**Proof.** Apply Corollary 3.4.3.2 in the case $K = \Delta^0$. 

**Corollary 3.4.3.4.** Let $q: \mathcal{C}^\circ \to \mathcal{O}^\circ$ be a fibration of $\infty$-operads, where $\mathcal{O}^\circ$ is coherent. Then:

(1) The functor $\phi: \text{Mod}^O(\mathcal{C})^\circ \to \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ is a Cartesian fibration.

(2) A morphism $f \in \text{Mod}^O(\mathcal{C})^\circ$ is $\phi$-Cartesian if and only if its image in $\mathcal{C}^\circ$ is an equivalence.

**Proof.** Let $M \in \text{Mod}^O_A(\mathcal{C})^\circ$ and let $\langle n \rangle$ denote its image in $N(\text{Fin}_n)$. Suppose we are given a morphism $f_0: A' \to A$ in $\text{Alg}_{/\mathcal{O}}(\mathcal{C})$; we will to construct a $\phi$-Cartesian morphism $f: M' \to M$ lifting $f_0$.

Choose inert morphisms $g_i: M \to M_i$ in $\text{Mod}^O(\mathcal{C})^\circ$ lying over $\rho^i: \langle n \rangle \to \langle 1 \rangle$ for $1 \leq i \leq n$. These maps determine a diagram $F: \langle n \rangle^{\circ \circ} \to \text{Mod}^O(\mathcal{C})^\circ_X$. Let $X_i$ denote the image of $M_i$ in $\mathcal{O}$, and let $\phi_i: \text{Mod}^O(\mathcal{C})_{X_i} \to \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ be the restriction of $\phi$. Using Corollary 3.4.3.3, we can choose $\phi_i$-Cartesian morphisms $f_i: M'_i \to M_i$ in $\text{Mod}^O(\mathcal{C})_{X_i}$ lying over $f_0$, whose images in $\mathcal{C}_{X_i}$ are equivalences. Since $q: \text{Mod}^O(\mathcal{C})^\circ \to \text{Alg}_{/\mathcal{O}}(\mathcal{C}) \times \mathcal{O}^\circ$ is a $\text{Alg}_{/\mathcal{O}}(\mathcal{C})$-family of $\infty$-operads, we can choose a $q$-limit diagram $F': \langle n \rangle^{\circ \circ} \to \text{Mod}^O(\mathcal{C})^\circ_X$ with $F'(i) = M'_i$ for $1 \leq i \leq n$, where $F'$ carries the cone point of $\langle n \rangle^{\circ \circ}$ to $M' \in \text{Mod}^O_A(\mathcal{C})^\circ_X$. Using the fact that $F'$ is a $q$-limit diagram, we get a natural transformation of functors $F' \to F$, which we may view as a diagram $H: \langle n \rangle^{\circ \circ} \times \Delta^1 \to \text{Mod}^O(\mathcal{C})^\circ$.

Let $v$ denote the cone point of $\langle n \rangle^{\circ \circ}$, and let $f = H|\{v\} \times \Delta^1$. Since each composition

$$\{i\} \times \Delta^1 \xrightarrow{H} \text{Mod}^O(\mathcal{C})^\circ \xrightarrow{f} \mathcal{C}^\circ$$

is an equivalence for $1 \leq i \leq n$, the assumption that $\mathcal{C}^\circ$ is an $\infty$-operad guarantees also that the image of $f$ in $\mathcal{C}^\circ$ is an equivalence. We will prove that $f$ is a $\phi$-coCartesian lift of $f_0$. In fact, we will prove the slightly stronger assertion that $f$ is $q$-Cartesian. Since the inclusion $\{v\} \subseteq \langle n \rangle^{\circ \circ}$ is right cofinal, it will suffice to show that $H|\langle n \rangle^{\circ \circ} \times \{1\}$ is a $q$-limit diagram. Since $H|\langle n \rangle^{\circ \circ} \times \{1\}$ is a $q$-right Kan extension of $H|\langle n \rangle^{\circ \circ} \times \{1\}$, it will suffice to show that the restriction $H|\langle n \rangle^{\circ \circ} \times \Delta^1$ is a $q$-right Kan extension of $H|\langle n \rangle^{\circ \circ} \times \{1\}$ (this follows from the construction, since the maps $f_i$ are $\phi_i$-Cartesian and therefore also $q$-Cartesian, by virtue of Theorem 3.4.3.1). Using Lemma T.4.3.2.7 again, we are reduced to showing that $H|\langle n \rangle^{\circ \circ} \times \Delta^1$ is a $q$-limit diagram. Since the inclusion $\langle n \rangle^{\circ \circ} \times \{0\} \subseteq \langle n \rangle^{\circ \circ} \times \Delta^1$ is right cofinal, it suffices to show that $F' = H|\langle n \rangle^{\circ \circ} \times \{0\}$ is a $q$-limit diagram, which follows from our assumption.

The above argument shows that for every $M \in \text{Mod}^O_A(\mathcal{C})^\circ$ and every morphism $f_0: A' \to A$ in $\text{Alg}_{/\mathcal{O}}(\mathcal{C})$, there exists a $\phi$-Cartesian morphism $f: M' \to M$ lifting $f_0$ whose image in $\mathcal{C}^\circ$ is an equivalence. This immediately implies (1), and the “only if” direction of (2) follows from the uniqueness properties of Cartesian
morphism. To prove the "if" direction of (2), suppose that $g : M'' \to M$ is a lift of $f_0$ whose image in $\mathcal{C}^\otimes$ is an equivalence, and let $f : M' \to M$ be as above. Since $f$ is $\phi$-Cartesian, we have a commutative diagram

$$
\begin{array}{ccc}
M' & \xrightarrow{f} & M \\
\downarrow{h} & & \downarrow{g} \\
M'' & \xrightarrow{h} & M
\end{array}
$$

to prove that $g$ is $\phi$-Cartesian it will suffice to show that $h$ is an equivalence. Since $\text{Mod}_{\mathcal{O}}(\mathcal{C})^\otimes$ is an $\infty$-operad, it suffices to show that each of the maps $h_i = \rho_i(h)$ is an equivalence in $\text{Mod}_{\mathcal{O}}(\mathcal{C})^\otimes$, for $1 \leq i \leq n$. This follows from Corollary 3.4.3.3, since each $h_i$ maps to an equivalence in $\mathcal{C}$.

**Corollary 3.4.3.5.** Let $\mathcal{O}^\otimes$ be a coherent $\infty$-operad, and let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a $\mathcal{O}$-monoidal $\infty$-category. Let $X \in \mathcal{O}$, and suppose we are given a commutative diagram

$$
\begin{array}{ccc}
K & \xrightarrow{p} & \text{Mod}_{\mathcal{O}}(\mathcal{C})^\otimes \\
\downarrow{\phi} & & \downarrow{\psi} \\
K^\otimes & \xrightarrow{\phi_X} & \text{Alg}_{\mathcal{O}}(\mathcal{C})
\end{array}
$$

such that the induced diagram $K \to \mathcal{C}_X^\otimes$ admits a limit. Then there extension $\overline{p}$ of $p$ (as indicated in the diagram) which is a $\psi_X$-limit diagram. Moreover, an arbitrary extension $\overline{p}$ of $p$ (as in the diagram) is a $\psi_X$-limit if and only if it induces a limit diagram $K^\otimes \to \mathcal{C}_X^\otimes$.

**Proof.** Combine Corollary 3.4.3.2 with Corollary T.4.3.1.15.

**Corollary 3.4.3.6.** Let $\mathcal{O}^\otimes$ be a coherent $\infty$-operad, let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a coCartesian fibration of $\infty$-operads, and let $X \in \mathcal{O}$. Assume that the $\infty$-category $\mathcal{C}_X^\otimes$ admits $K$-indexed limits, for some simplicial set $K$. Then:

1. For every algebra object $A \in \text{Alg}_{\mathcal{O}}(\mathcal{C})$, the $\infty$-category $\text{Mod}_{\mathcal{O}}(\mathcal{C})^\otimes, X$ admits $K$-indexed limits.

2. A functor $\overline{p} : K^{\otimes 1} \to \text{Mod}_{\mathcal{O}}(\mathcal{C})^\otimes, X$ is a limit diagram if and only if it induces a limit diagram $K^{\otimes 1} \to \mathcal{C}_X^\otimes$.

We now turn to the proof of Theorem 3.4.3.1. First, choose an inner anodyne map $K \to K'$, where $K'$ is an $\infty$-category. Since $\text{Alg}_{\mathcal{O}}(\mathcal{C}) \times \mathcal{O}^\otimes$ is an $\infty$-category and $\psi$ is a categorical fibration, we can extend our commutative diagram as indicated:

$$
\begin{array}{ccc}
K & \xrightarrow{p} & \text{Mod}_{\mathcal{O}}(\mathcal{C})^\otimes \\
\downarrow{\phi} & & \downarrow{\psi} \\
K^{\otimes 1} & \xrightarrow{\phi_X} & \text{Alg}_{\mathcal{O}}(\mathcal{C}) \times \mathcal{O}^\otimes
\end{array}
$$

Using Proposition T.A.2.3.1, we see that it suffices to prove Theorem 3.4.3.1 after replacing $K$ by $K'$. We may therefore assume that $K$ is an $\infty$-category. In this case, the desired result is a consequence of the following:

**Proposition 3.4.3.7.** Let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a fibration of $\infty$-operads, where $\mathcal{O}^\otimes$ is coherent. Let $K$ be an $\infty$-category. Suppose we are given a commutative diagram

$$
\begin{array}{ccc}
K & \xrightarrow{p} & \text{Mod}_{\mathcal{O}}(\mathcal{C})^\otimes \\
\downarrow{\phi} & & \downarrow{\psi} \\
K^{\otimes 1} & \xrightarrow{\phi_X} & \text{Alg}_{\mathcal{O}}(\mathcal{C})
\end{array}
$$
where the induced diagram $K^a \to \mathcal{O}^\otimes$ is the constant map taking some value $C \in \mathcal{O}$. Assume that:

(**) The induced lifting problem

\[
\begin{array}{ccc}
K & \xrightarrow{p'} & \mathcal{C} \\
\downarrow & & \downarrow q \\
K^a & \xrightarrow{\delta} & \mathcal{O}^\otimes
\end{array}
\]

admits a solution, where $p'$ is a $q$-limit diagram.

Then:

1. There exists a map $p$ making the original diagram commute, such that $\delta \circ p$ is a $q$-limit diagram in $\mathcal{C}^\otimes$ (here $\delta : \text{Mod}^\otimes(\mathcal{C}) \to \mathcal{C}^\otimes$ denotes the map given by composition with the diagonal embedding $\mathcal{O}^\otimes \to \mathcal{K}_\mathcal{O} \subseteq \text{Fun}(\Delta^1, \mathcal{O}^\otimes)$).

2. Let $p'$ be an arbitrary map making the above diagram commute. Then $p'$ is a $\psi$-limit diagram if and only if $\delta \circ p'$ is a $q$-limit diagram.

The proof of Proposition 3.4.3.7 will require some preliminaries. We first need the following somewhat more elaborate version of Proposition B.4.12:

**Proposition 3.4.3.8.** Suppose we are given a diagram of $\infty$-categories $X \xrightarrow{\phi} Y \xrightarrow{\pi} Z$ where $\pi$ is a flat categorical fibration and $\phi$ is a categorical fibration. Let $Y' \subseteq Y$ be a full subcategory, let $X' = X \times_Y Y'$, let $\pi' = \pi|Y'$, and let $\psi : \pi_*X \to \pi'_*X'$ be the canonical map. (See Notation B.4.4.) Let $K$ be an $\infty$-category and $\mathcal{O}_0 : K^a \to \pi'_*X'$ a diagram. Assume that the following conditions are satisfied:

(i) The full subcategory $Y' \times_Z K^a \subseteq Y \times_Z K^a$ is a cosieve on $Y$.

(ii) For every object $y \in Y'$ and every morphism $f : z \to \pi(y)$ in $Z$, there exists a $\pi$-Cartesian morphism $\overline{f} : \overline{z} \to y$ in $Y'$ such that $\pi(\overline{f}) = f$.

(iii) Let $\pi''$ denote the projection map $K^a \times_Z Y \to K^a$. Then $\pi''$ is a coCartesian fibration.

(iv) Let $v$ denote the cone point of $K^a$, let $\mathcal{C} = \pi''^{-1}\{v\}$, and let $\mathcal{C}' = \mathcal{C} \times_Y Y'$. Then $\mathcal{C}'$ is a localization of $\mathcal{C}$.

Condition (iii) implies that there is a map $\delta' : K^a \times \mathcal{C} \to K^a \times_Z Y$ which is the identity on $\{v\} \times \mathcal{C}$ and carries carries $e \times \{C\}$ to a $\pi''$-coCartesian edge of $K^a \times_Z Y$, for each edge $e$ of $K^a$ and each object $C$ of $\mathcal{C}$. Condition (iv) implies that there is a map $\delta'' : \mathcal{C} \times \Delta^1 \to \mathcal{C}$ such that $\delta''|\mathcal{C} \times \{0\} = \text{id}_{\mathcal{C}}$ and $\delta''|\{C\} \times \Delta^1$ exhibits $\delta''(C, 1)$ as a $\mathcal{C}'$-localization of $C$, for each $C \in \mathcal{C}$. Let $\delta$ denote the composition

\[
K^a \times \mathcal{C} \times \Delta^1 \xrightarrow{\delta''} K^a \times \mathcal{C} \xrightarrow{\delta} K^a \times_Z Y.
\]

Then:

1. Let $p : K^a \to \pi_*X$ be a map lifting $p_0$, corresponding to a functor $\overline{F} : K^a \times_Z Y \to X$. Suppose that for each $C \in \mathcal{C}$, the induced map

\[
K^a \times \{C\} \times \Delta^1 \hookrightarrow K^a \times \mathcal{C} \xrightarrow{\delta} K^a \times_Z Y \xrightarrow{\overline{F}} X
\]

is a $\phi$-limit diagram. Then $p'$ is a $\psi$-limit diagram.
3.4. GENERAL FEATURES OF MODULE $\infty$-CATEGORIES

(2) Suppose that $p : K^a \to \pi_* X$ is a map lifting $p_0 = p_0|K$, corresponding to a functor $F : (K^a \times Z Y') \coprod_{K \times Z Y}(K \times Z Y) \to X$. Assume furthermore that for each $C \in \mathcal{C}$, the induced map

$$\theta : (K^a \times \{C\} \times \{1\}) \coprod_{K \times \{C\} \times \{1\}} (K \times \{C\} \times \Delta^1) \to (K \times \{C\} \times \{1\}) \coprod_{K \times \{C\} \times \{1\}} (K \times \{C\} \times \Delta^1)$$

\[\delta \quad \rightarrow \quad (K^a \times Z Y') \coprod_{K \times Z Y'} (K \times Z Y) \rightarrow X \]

can be extended to a $\psi$-limit diagram lifting the map

$$K^a \times \{C\} \times \Delta^1 \rightarrow K^a \times \mathcal{C} \times \Delta^1 \rightarrow K^a \times Z Y \rightarrow Y.$$

Then there exists an extension $\bar{p} : K^a \to \pi_* X$ of $p$ lifting $p_0$ which satisfies condition (1).

Proof. Let $W = K^a \times Z Y$ and let $W_0$ denote the coproduct $(K^a \times Z Y') \coprod_{K \times Z Y}(K \times Z Y)$; condition (i) allows us to identify $W_0$ with a full subcategory of $W$. Let $\bar{p} : K^a \to \pi_* X$ satisfy the condition described in (1), corresponding to a functor $\overline{F} : W \to X$. In view of assumptions (i), (ii), and Proposition B.4.9, it will suffice to show that $\overline{F}$ is a $\phi$-right Kan extension of $F = \overline{F}|W_0$. Pick an object $C \in \mathcal{C}$; we wish to show that $\overline{F}$ is a $\phi$-right Kan extension of $F$ at $C$. In other words, we wish to show that the map

$$(W_0 \times_W W_{C/})^a \rightarrow W \xrightarrow{\overline{F}} X$$

is a $\phi$-limit diagram. Restricting $\delta$, we obtain a map $K^a \times \{C\} \times \Delta^1 \rightarrow W$, which we can identify with a map

$$s : (K^a \times \{C\} \times \{1\}) \coprod_{K \times \{C\} \times \{1\}} (K \times \{C\} \times \Delta^1) \rightarrow W' \times_W W_{C/}.$$

Since $\bar{p}$ satisfies (1), it will suffice to show that $s$ is right cofinal. We have a commutative diagram

The map $\theta$ is evidently a coCartesian fibration, and $\theta'$ is a coCartesian fibration by virtue of assumptions (i) and (iii). Moreover, the map $s$ carries $\theta$-coCartesian edges to $\theta'$-coCartesian edges. Invoking Lemma 7.1.2.6, we are reduced to showing that for each vertex $k$ of $K^a$, the map of fibers $s_k$ is right cofinal. If $k = v$ is the cone point of $K^a$, then we are required to show that $s$ carries $\{v\} \times \{C\} \times \{1\}$ to an initial object of $\mathcal{C}/C_j$: this follows from the definition of $\delta'$. If $k \neq v$, then we are required to show that $s$ carries $K^a \times \{C\} \times \{0\}$ to an initial object of $W_{C_j} \times K \times \{k\}$, which follows from our assumption that $\delta$ carries $\{v\} \times \{C\} \times \{0\}$ to a $\pi''$-coCartesian edge of $W$. This completes the proof of (1).

We now prove (2). The diagram $p$ gives rise to a map $F : W_0 \rightarrow X$ fitting into a commutative diagram

The above argument shows that a dotted arrow $\overline{F}$ as indicated will correspond to a map $\bar{p} : K^a \rightarrow \pi_* X$ satisfying (1) if and only if $\overline{F}$ is a $\phi$-right Kan extension of $F$. In view of Lemma T.4.3.2.13, the existence of such an extension is equivalent to the requirement that for each $C \in \mathcal{C}$, the diagram

$$W_0 \times_W W_{C/} \rightarrow W_0 \rightarrow X$$

is right cofinal.
can be extended to a \( \phi \)-limit diagram lifting the map

\[
(W_0 \times_W W_C)^s \to W \to Y.
\]

This follows from the hypothesis of part (2) together with the right cofinality of the map \( s \) considered in the proof of (1).

**Definition 3.4.3.9.** Let \( \langle n \rangle \) be an object of \( \Fin_* \). A splitting of \( \langle n \rangle \) is a pair of inert morphisms \( \alpha : \langle n \rangle \to \langle n_0 \rangle \), \( \beta : \langle n \rangle \to \langle n_1 \rangle \) with the property that the map \( (\alpha^{-1} \prod \beta^{-1}) : \langle n_0 \rangle^\circ \prod \langle n_1 \rangle^\circ \to \langle n \rangle^\circ \) is a bijection.

More generally, let \( K \) be a simplicial set. A splitting of a diagram \( p : K \to N(\Fin_*) \) is a pair of natural transformations \( \alpha : p \to p_0 \), \( \beta : p \to p_1 \) with the following property: for every vertex \( k \) of \( K \), the morphisms \( \alpha_k : p(k) \to p_0(k) \) and \( \beta_k : p(k) \to p_1(k) \) determine a splitting of \( p(k) \).

We will say that a natural transformation \( \alpha : p \to p_0 \) of diagrams \( p, p_0 : K \to N(\Fin_*) \) splits if there exists another natural transformation \( \beta : p \to p_1 \) which gives a splitting of \( p \).

**Remark 3.4.3.10.** Let \( \alpha : p \to p_0 \) be a natural transformation of diagrams \( p, p_0 : K \to N(\Fin_*) \). If \( \alpha \) splits, then the natural transformation \( \beta : p \to p_1 \) which provides the splitting of \( p \) is well-defined up to (unique) equivalence. Moreover, a bit of elementary combinatorics shows that \( \alpha \) splits if and only if it satisfies the following conditions:

1. The natural transformation \( \alpha \) is inert: that is, for each vertex \( k \in K \), the map \( \alpha_k : p(k) \to p_0(k) \) is an inert morphism in \( \Fin_* \).
2. For every edge \( e : x \to x' \) in \( K \), consider the diagram

\[
\begin{array}{ccc}
\langle n \rangle & \xrightarrow{\alpha} & \langle n_0 \rangle \\
\downarrow^{p(e)} & & \downarrow^{p_0(e)} \\
\langle m \rangle & \xleftarrow{\alpha'} & \langle m_0 \rangle
\end{array}
\]

in \( \Fin_* \) obtained by applying \( \alpha \) to \( e \). Then \( p(e) \) carries \((\alpha_x^{-1}(n_0))^\circ \subseteq \langle n \rangle \) into \((\alpha'_x^{-1}(m_0))^\circ \subseteq \langle m \rangle \).

**Definition 3.4.3.11.** Let \( q : \mathcal{O}^\circ \to N(\Fin_*) \) be an \( \infty \)-operad. We will say that a natural transformation \( \alpha : p \to p_0 \) of diagrams \( p, p_0 : K \to \mathcal{O}^\circ \) is inert if the induced map \( \alpha_k : p(k) \to p_0(k) \) is an inert morphism in \( \mathcal{O}^\circ \) for every vertex \( k \in K \).

A splitting of \( p : K \to \mathcal{O}^\circ \) is a pair of inert natural transformations \( \alpha : p \to p_0 \), \( \beta : p \to p_1 \) such that the induced transformations \( q \circ p_0 \leftarrow q \circ p \to q \circ p_1 \) determine a splitting of \( q \circ p : K \to N(\Fin_*) \), in the sense of Definition 3.4.3.9.

We will say that an inert natural transformation \( \alpha : p \to p_0 \) is split if there exists another inert natural transformation \( \beta : p \to p_1 \) such that \( \alpha \) and \( \beta \) are a splitting of \( p \). In this case, we will say that \( \beta \) is a complement to \( \alpha \).

**Lemma 3.4.3.12.** Let \( q : \mathcal{O}^\circ \to N(\Fin_*) \) and let \( \alpha : p \to p_0 \) be an inert natural transformation of diagrams \( p, p_0 : K \to \mathcal{O}^\circ \). The following conditions are equivalent:

1. The natural transformation \( \alpha \) is split: that is, there exists a complement \( \beta : p \to p_1 \) to \( \alpha \).
2. The natural transformation \( \alpha \) induces a split natural transformation \( \overline{\alpha} : q \circ p \to q \circ p_0 \).

Moreover, if these conditions are satisfied, then \( \beta \) is determined uniquely up to equivalence.

**Proof.** The implication (1) \( \Rightarrow \) (2) is clear: if \( \beta : p \to p_1 \) is a complement to \( \alpha \), then the induced transformations \( q \circ p_0 \leftarrow q \circ p \to q \circ p_1 \) form a splitting of \( q \circ p : K \to N(\Fin_*) \). Conversely, suppose that \( q \circ p \) is split, and choose a complement \( \overline{\beta} : q \circ p \to p_1 \) to \( \overline{\alpha} \). Then \( \overline{\beta} \) is inert, so we can choose a \( q \)-coCartesian lift \( \beta : p \to p_1 \) of \( \overline{\beta} \) which is a complement to \( \alpha \). The uniqueness of \( \beta \) follows from the observation that \( \overline{\beta} \) and its \( q \)-coCartesian lift are both well-defined up to equivalence. \( \square \)
3.4. GENERAL FEATURES OF MODULE $\infty$-CATEGORIES

Lemma 3.4.3.13. Let $q : C^\otimes \to O^\otimes$ be a fibration of $\infty$-operads. Let $\alpha : X \to X_0$ and $\beta : X \to X_1$ be morphisms in $O^\otimes$ which determine a splitting of $X$, and suppose that $X_0$ and $X_1$ are objects of $C^\otimes$ lying over $X_0$ and $X_1$, respectively. Then:

1. Let $\overline{\alpha} : \overline{X} \to \overline{X}_0$ and $\overline{\beta} : \overline{X} \to \overline{X}_1$ be morphisms in $C^\otimes$ lying over $\alpha$ and $\beta$. Then $\overline{\alpha}$ and $\overline{\beta}$ determine a splitting of $\overline{X}$ if and only if they exhibit $\overline{X}$ as a $q$-product of $\overline{X}_0$ and $\overline{X}_1$.

2. There exist morphisms $\overline{\alpha} : \overline{X} \to \overline{X}_0$ and $\overline{\beta} : \overline{X} \to \overline{X}_1$ satisfying the equivalent conditions of (1).

Proof. We will prove (2) and the “if” direction of (1); the “only if” direction follows from (2) together with the uniqueness properties of $q$-limit diagrams. We begin with (1). Choose a diagram $\sigma : \Delta^1 \times \Delta^1 \to C^\otimes$

$$
\begin{array}{ccc}
X & \xrightarrow{\pi} & X_0 \\
\downarrow{\beta} & & \downarrow{q(\gamma)} \\
X_1 & \longrightarrow & 0,
\end{array}
$$

where 0 is a final object of $C^\otimes$ (in other words, 0 lies in $C\otimes(0)$). Let $K \simeq \Lambda^2_0$ denote the full subcategory of $\Delta^1 \times \Delta^1$ obtained by removing the final object. Since 0 is final in $C^\otimes$ and $q(0)$ is final in $O^\otimes$, we deduce that $\sigma$ is a $q$-final object of $C^\otimes$ (Proposition T.4.3.1.5), so that $\sigma$ is a $q$-right Kan extension of $\sigma|K$. It follows from Proposition 2.3.2.5 that the $\sigma$ is a $q$-limit diagram. Applying Lemma T.4.3.2.7, we deduce that $\sigma|K$ is a $q$-limit, so that $\sigma$ exhibits $\overline{X}$ as a $q$-product of $\overline{X}_0$ and $\overline{X}_1$.

We now prove (2). Let 0 be an object of $C\otimes(0)$. Since 0 is a final object of $C^\otimes$, we can find morphisms (automatically inert) $\gamma : X_0 \to 0$ and $\delta : X_1 \to 0$ in $C^\otimes$. Since $q(0)$ is a final object of $O^\otimes$, we can find a commutative square

$$
\begin{array}{ccc}
X & \xrightarrow{\alpha} & X_0 \\
\downarrow{\beta} & & \downarrow{q(\gamma)} \\
X_1 & \longrightarrow & q(0),
\end{array}
$$

in $O^\otimes$. Using Proposition 2.3.2.5, deduce the existence of a $q$-limit diagram $\sigma :$

$$
\begin{array}{ccc}
X & \xrightarrow{\pi} & X_0 \\
\downarrow{\gamma} & & \downarrow{\gamma} \\
X_1 & \longrightarrow & 0,
\end{array}
$$

in $C^\otimes$, where $\overline{\pi}$ and $\overline{\gamma}$ are inert and therefore determine a splitting of $\overline{X}$.

Corollary 3.4.3.14. Let $q : C^\otimes \to O^\otimes$ be a fibration of $\infty$-operads, let $X$ be the full subcategory of $\text{Fun}(\Lambda^2_0, C^\otimes)$ be the full subcategory spanned by those diagrams $X_0 \leftarrow X \to X_1$ which determine a splitting of $X$, and let $Y \subseteq \text{Fun}(\Lambda^2_0, O^\otimes)$ be defined similarly. Then the canonical map

$$
X \to Y \times_{\text{Fun}(\{1\}, C^\otimes) \times \text{Fun}(\{2\}, O^\otimes)} (\text{Fun}(\{1\}, C^\otimes) \times \text{Fun}(\{2\}, C^\otimes))
$$

is a trivial Kan fibration.

Proof. Combine Lemma 3.4.3.13 with Proposition T.4.3.2.15.

Lemma 3.4.3.15. Let $q : C^\otimes \to O^\otimes$ be a fibration of $\infty$-operads. Suppose we are given a split natural transformation $\alpha : p \to p_0$ of diagrams $p, p_0 : K^\otimes \to O^\otimes$. Let $\overline{p}_0 : K^\otimes \to C^\otimes$ be a diagram lifting $p_0$, let $\overline{p}' : K \to C^\otimes$ be a diagram lifting $\overline{p}' = \overline{p}_0K$, and let $\overline{\alpha} : \overline{p}' \to \overline{p}_0K$ be a natural transformation lifting $\alpha' = \alpha|\Delta^1 \times K$. Suppose that the following condition is satisfied:

$$
\text{(condition)}
$$
Let \( \beta : p \to p_1 \) be a complement to \( \alpha \), let \( \beta' = \beta|\Delta^1 \times K \), and let \( \overline{\beta}' : \overline{p}' \to \overline{p}'_1 \) be a q-coCartesian natural transformation lifting \( \beta' \) (so that \( \overline{\beta} \) is a complement to \( \overline{\alpha}' \)). Then \( \overline{p}'_1 \) can be extended to a \( \ell \)-limit diagram \( \overline{p}_1 : K^\odot \to G^\odot \) such that \( q \circ \overline{p}_1 = p_1 \).

Then:

1. Let \( \overline{\alpha} : \overline{p} \to \overline{p}_0 \) be a natural transformation of diagrams \( \overline{p} : p : K^\odot \to G^\odot \) which extends \( \overline{\alpha}' \) and lies over \( \alpha \). The following conditions are equivalent:
   
   (i) The map of simplicial sets \( \overline{\alpha} : \Delta^1 \times K^\odot \to G^\odot \) is a \( \ell \)-limit diagram.
   
   (ii) The natural transformation \( \overline{\alpha} \) is inert (and therefore split), and if \( \overline{\beta} : \overline{p} \to \overline{p}_1 \) is a complement to \( \overline{\alpha} \), then \( \overline{p}_1 \) is a \( \ell \)-limit diagram.

2. There exists a natural transformation \( \overline{\alpha} : \overline{p} \to \overline{p}_0 \) satisfying the equivalent conditions of (1).

Proof. We first prove the implication (ii) \( \Rightarrow \) (i) of assertion (1). Choose a complement \( \overline{\beta} : \overline{p} \to \overline{p}_1 \) to \( \overline{\alpha} \), so that \( \overline{\alpha} \) and \( \overline{\beta} \) together determine a map \( F : \Lambda^2_0 \times K^\odot \to G^\odot \) with \( F|\Delta^0 \times K^\odot = \overline{\alpha} \) and \( F|\Delta^1 \times K^\odot = \overline{\beta} \).

Using the small object argument, we can choose an inner anodyne map \( K \to K' \) which is bijective on vertices, where \( K' \) is an \( \infty \)-category. Since \( G^\odot \) is an \( \infty \)-category, the map \( F \) factors as a composition \( \Lambda^2_0 \times \Lambda^2_0 \to K^\odot \times \Lambda^2_0 \to G^\odot \). We may therefore replace \( K \) by \( K' \) and thereby reduce to the case where \( K \) is an \( \infty \)-category.

The inclusion \( i : K \times \{0\} \subseteq K \times \Delta^{0,2} \) is left anodyne, so that \( i \) is right cofinal. It will therefore suffice to show that the restriction \( F_0 \) of \( F \) to \( (K^\odot \times \Delta^{0,1}) \coprod_{K \times \{0\}} (K \times \Delta^{0,2}) \) is a \( \ell \)-limit diagram. Since \( \overline{p}_1 \) is a \( \ell \)-limit diagram, \( F \) is a \( \ell \)-right Kan extension of \( F_0 \); according to Lemma T.4.3.2.7 it will suffice to prove that \( F_\ell \) is a \( \ell \)-limit diagram.

Let \( v \) denote the cone point of \( K^\odot \). Let \( D \) be the full subcategory of \( K^\odot \times \Lambda^2_0 \) spanned by \( K^\odot \times \{1\}, K^\odot \times \{2\} \), and \( (v,0) \). Using Lemma 3.4.3.13, we deduce that \( F_\ell \) is a \( \ell \)-right Kan extension of \( F|D \). Using Lemma T.4.3.2.7 again, we are reduced to proving that \( F|D \) is a \( \ell \)-limit diagram. Since the inclusion

\[
\{(v,1)\} \coprod \{(v,2)\} \subseteq (K^\odot \times \{1\}) \coprod (K^\odot \times \{2\})
\]

is right cofinal, it suffices to show that \( F|\{v\} \times \Lambda^2_0 \) is a \( \ell \)-limit diagram, which follows from Lemma 3.4.3.13. This completes the verification of condition (i).

We now prove (2). Choose a complement \( \beta : p \to p_1 \) to the split natural transformation \( \alpha \), let \( \beta' = \beta|\Delta^1 \times K \), and choose a q-coCartesian natural transformation \( \overline{\beta}' : \overline{p}' \to \overline{p}'_1 \) lifting \( \beta' \). Invoking assumption (\( \star \)), we can extend \( \overline{p}'_1 \) to a \( \ell \)-limit diagram \( \overline{p}_1 : K^\odot \to G^\odot \) such that \( q \circ \overline{p}_1 = p_1 \). The maps \( \overline{p}_0, \overline{p}_1, \overline{\alpha}' \) and \( \overline{\beta}' \) can be amalgamated to give a map

\[
F : (\Lambda^2_0 \times K) \coprod_{(\{1,2\} \times K)} \{(1,2) \times K^\odot \} \to G^\odot.
\]

Using Corollary 3.4.3.14, we can extend \( F \) to a map \( F' : \Lambda^2_0 \times K^\odot \to G^\odot \) corresponding to a pair of morphisms \( \overline{\alpha} : \overline{p} \to \overline{p}_0 \) and \( \overline{\beta} : \overline{p} \to \overline{p}_1 \) having the desired properties.

The implication (i) \( \Rightarrow \) (ii) of (1) now follows from (2), together with the uniqueness properties of \( \ell \)-limit diagrams.

Proof of Proposition 3.4.3.7. We first treat the case where \( K \) is an \( \infty \)-category. Let \( Y = X_0 \) and \( Y' = X_0^0 \subseteq Y \). Let \( \pi : Y \to X_0 \) be the map given by evaluation at \( \{0\} \), and let \( \pi' = \pi|Y' \). Our assumption that \( X_0^0 \) is coherent guarantees that \( \pi \) is a flat categorical fibration. Let \( X = Y \times_{\operatorname{Fun}(1) \times X_0} X_0^0 \), and let \( X' = X \times_Y Y' \).

The map \( \psi : \operatorname{Mod}(O_0)^0 \to \operatorname{pAlg}_{O_0}(O) \) can be identified with a restriction of the map \( \pi_* X \to \pi'_* X' \). We are
We claim that this situation satisfies the hypotheses of Proposition 3.4.3.8:

(i) The full subcategory $Y' \times_{O^\otimes} K'$ is a cosieve on $Y \times_{O^\otimes} K'$. Since the map $K'^d \to O^\otimes$ is constant taking some value $C \in O$, it will suffice to show that the $Y' \times_{O^\otimes} \{C\}$ is a cosieve on $Y \times_{O^\otimes} \{C\}$. Unwinding the definitions, this amounts to the following assertion: given a commutative diagram

$$
\begin{array}{ccc}
C & \longrightarrow & D \\
\downarrow \text{id} & & \downarrow \\
C & \longrightarrow & D'
\end{array}
$$

in $O^\otimes$, if the upper horizontal map is null then the lower horizontal map is null. This is clear, since the collection of null morphisms in $O^\otimes$ is closed under composition with other morphisms.

(ii) For every object $y \in Y'$ and every morphism $f : z \to \pi(y)$ in $O$, there exists a $\pi$-Cartesian morphism $\overline{f} : \pi \to y$ in $Y'$ such that $\pi(\overline{f}) = f$. We can identify $y$ with a semi-inert morphism $y_0 \to y_1$ in $O^\otimes$, and $f$ with a morphism $z \to y_0$ in $O^\otimes$. Using Corollary T.2.4.7.12, we see that the morphism $\overline{f}$ can be taken to correspond to the commutative diagram

$$
\begin{array}{ccc}
z & \longrightarrow & y_1 \\
\downarrow & & \downarrow \text{id} \\
y_0 & \longrightarrow & y_1
\end{array}
$$

in $O^\otimes$: our assumption that $y_0 \to y_1$ is null guarantees that the composite map $z \to y$ is also null.

(iii) Let $\pi''$ denote the projection map $K'^d \times_{O^\otimes} Y \to K'^d$. Then $\pi''$ is a coCartesian fibration. This is clear, since $\pi''$ is a pullback of the coCartesian fibration $(K_{O^\otimes} \times_{O^\otimes} \{C\}) \to \Delta^0$.

(iv) Let $v$ denote the cone point of $K'$ and let $D = \pi''^{-1}\{v\}$. Then $D' = D \times_{Y'} Y'$ is a localization of $D$. We can identify an object of $D$ with a semi-inert morphism $f : C \to C'$ in $O^\otimes$. We wish to prove that for any such object $f$, there exists a morphism $f \to g$ in $D$ which exhibits $g$ as a $D'$-localization of $f$. Let $f_0 : \langle 1 \rangle \to \langle k \rangle$ denote the underlying morphism in $\mathcal{F}_{\text{in}}$. If $f_0$ is null, then $f \in D'$ and there is nothing to prove. Otherwise, $f_0(1) = i$ for some $1 \leq i \leq k$. Choose an inert map $h_0 : \langle k \rangle \to \langle k - 1 \rangle$ such that $h_0(i) = \ast$, and choose an inert morphism $h : C' \to D$ in $O^\otimes$ lifting $h_0$. We then have a commutative diagram

$$
\begin{array}{ccc}
C & \longrightarrow & C' \\
\downarrow \text{id} & & \downarrow h \\
C & \longrightarrow & D
\end{array}
$$

in $O^\otimes$, corresponding to a map $\alpha : f \to g$ in $D$; by construction, $g$ is null so that $g \in D'$. We claim that $\alpha$ exhibits $g$ as a $D'$-localization of $\mathcal{E}$. To prove this, choose any object $g' : C \to D'$ in $D'$; we wish to show that composition with $\alpha$ induces a homotopy equivalence

$$
\text{Map}_D(g, g') \simeq \text{Map}_{O^\otimes}\mathcal{C}/(g, g') \to \text{Map}_{O^\otimes}\mathcal{C}/(f, g') \simeq \text{Map}_D(f, g).
$$
Since the projection map

\[(\mathcal{O}^\otimes)_{C/} \to \mathcal{O}^\otimes\]

is a left fibration, it will suffice to show that the map \(\text{Map}_{\mathcal{O}^\otimes}(D, D') \to \text{Map}_{\mathcal{O}^\otimes}(C', D')\), where the superscript indicates that we consider only morphisms \(C' \to D'\) such that the underlying map \(\langle k \rangle \to \langle k' \rangle\) carries \(i\) to the base point \(* \in \langle k' \rangle\). Since \(h\) is inert, this follows from the observation that composition with \(h_0\) induces an injection \(\text{Hom}_{\mathcal{O}^\otimes}((k - 1), \langle k' \rangle) \to \text{Hom}_{\mathcal{O}^\otimes}((k), \langle k' \rangle)\) whose image consists of those maps which carry \(i\) to the base point.

Fix an object of \(\mathcal{D}\) corresponding to a semi-inert morphism \(f : C \to C'\) in \(\mathcal{O}^\otimes\), and let \(\alpha : f \to g\) be a map in \(\mathcal{D}\) which exhibits \(g\) as a \(\mathcal{D}'\)-localization of \(f\) (as in the proof of \((iv)\)). Using the maps \(p\) and \(\overline{p}_\psi\), we get commutative diagram

\[\begin{array}{ccc}
(K \times \Delta^1) \coprod_{K \times \{1\}} (K^q \times \{1\}) & \longrightarrow & \mathcal{O}^\otimes \\
\downarrow & & \downarrow \\
K^q \times \Delta^1 & \longrightarrow & \mathcal{O}^\otimes.
\end{array}\]

To apply Proposition 3.4.3.8, we must know that every such diagram admits an extension as indicated, where \(\theta\) is a \(q\)-limit. This follows from Lemma 3.4.3.15 and assumption \((*)\). Moreover, we obtain the following criterion for testing whether \(\theta\) is a \(q\)-limit diagram:

\((*)\) Let \(\theta : K^q \times \Delta^1 \to \mathcal{C}^\otimes\) be as above, and view \(\theta\) as a natural transformation \(d \to d_0\) of diagrams \(d, d_0 : K^q \to \mathcal{C}^\otimes\). Then \(\theta\) is a \(q\)-limit diagram if and only if it is an inert (and therefore split) natural transformation, and admits a complement \(d \to d_1\) where \(d_1 : K^q \to \mathcal{C}^\otimes\) is a \(q\)-limit diagram.

Applying Proposition 3.4.3.8, we obtain the following:

\((a)\) There exists a solution to the lifting problem

\[\begin{array}{ccc}
K & \longrightarrow & \widetilde{\text{Mod}}^\otimes_{\mathcal{O}} (\mathcal{C})^\otimes \\
\downarrow & \Downarrow \pi & \downarrow \psi \\
K^q & \longrightarrow & \text{Alg}_{/\mathcal{O}} (\mathcal{C}),
\end{array}\]

where \(p\) is an \(\overline{\psi}\)-limit diagram.

\((b)\) An arbitrary extension \(\overline{p}\) as above is an \(\overline{\psi}\)-limit diagram if and only if the following condition is satisfied:

\((**)\) For every object \(f : C \to C'\) in \(\mathcal{D}\) and every morphism \(\alpha : f \to g\) in \(\mathcal{D}\) which exhibits \(g\) as a \(\mathcal{D}'\)-localization of \(f\), if \(\theta : K^q \times \Delta^1 \to \mathcal{C}^\otimes\) is defined as above, then \(\theta\) is a split natural transformation of diagrams \(d, d_0 : K^q \to \mathcal{C}^\otimes\) and admits a complement \(d \to d_1\) where \(d_1 : K^q \to \mathcal{C}^\otimes\) is a \(q\)-limit diagram.

To complete the proof, we must show that condition \((**)\) is equivalent to the following pair of assertions:

\((1)\) The map \(\overline{p}\) carries \(K^q\) into the full subcategory \(\overline{\text{Mod}}^\otimes_{\mathcal{O}} (\mathcal{C})^\otimes \subseteq \widetilde{\text{Mod}}^\otimes_{\mathcal{O}} (\mathcal{C})^\otimes\). (Since we know already that \(p\) has this property, it suffices to check that \(\overline{p}\) carries the cone point \(v\) of \(K^q\) into \(\widetilde{\text{Mod}}^\otimes_{\mathcal{O}} (\mathcal{C})^\otimes\)).

\((II)\) The composite map

\[\overline{p} : K^q \to \widetilde{\text{Mod}}^\otimes_{\mathcal{O}} (\mathcal{C})^\otimes \to \mathcal{C}^\otimes\]

is a \(q\)-limit diagram. Here the second map is induced by composition with the diagonal embedding \(\mathcal{O}^\otimes \hookrightarrow \mathcal{K}_{\mathcal{O}}\).
Assume first that condition \((\ast'')\) is satisfied by \(\overline{p} : K^{\circ} \to \widetilde{\text{Mod}}^{\circ}(C)^{\circ}\); we will prove that \(\overline{p}\) also satisfies (I) and (II). We can identify \(\overline{p}\) with a map \(\overline{P} : K^{\circ} \times D \to C^{\circ}\). We first prove (II). Fix an object \(f \in D\) corresponding to an equivalence \(C \to C'\) in \(C^{\circ}\); we will show that \(\overline{P}_f = \overline{P}|K^{\circ} \times \{f\}\) is a \(q\)-limit diagram. Choose a morphism \(f \to g\) which exhibits \(g\) as a \(D'\)-localization of \(f\), and let \(\theta : \overline{P}_f \to \overline{P}_g\) be the induced natural transformation as in \((\ast'')\). Let \(\theta' : \overline{P}_f \to d_1\) be a complement to \(\theta\). Since \(C \simeq C'\), \(\overline{P}_g\) takes values in \(C^{\circ}_{(0)}\), so \(\theta'\) is an equivalence of diagrams. Condition \((\ast'')\) implies that \(d_1\) is a \(q\)-limit diagram, so that \(\overline{P}_f\) is a \(q\)-limit diagram.

To prove (I), we must show that for every morphism \(\alpha : f \to f'\) in \(D\) whose image in \(K_{(0)}\) is inert, the induced map \(\overline{P}(v, f) \to \overline{P}(v, f')\) is inert in \(C^{\circ}\). There are several cases to consider:

(I1) The map \(f\) belongs to \(D'\). Then \(f' \in D'\) and the desired result follows from our assumption that \(\overline{p}_0\) factors through \(P_{\text{Alg}}_{/C_0}(\mathcal{C})\).

(I2) The map \(f\) does not belong to \(D'\), but \(f'\) does. Then \(\alpha\) factors as a composition

\[ f \overset{\alpha'}{\to} g \overset{\alpha''}{\to} f', \]

where \(\alpha'\) exhibits \(g\) as a \(\mathcal{D}'\)-localization of \(f\). Since the composition of inert morphisms in \(\mathcal{C}^{\circ}\) is inert and \(g \in D'\), we can apply (I1) to reduce to the case where \(\alpha = \alpha'\). In this case, the desired result follows immediately from \((\ast'')\).

(I3) The map \(f'\) is an equivalence in \(\mathcal{C}^{\circ}\). Let \(\overline{\alpha} : \overline{P}_f \to \overline{P}_{f'}\) be the natural transformation induced by \(\alpha\); it will suffice to show that this natural transformation in inert. Let \(\beta : f \to g\) be a map in \(D\) which exhibits \(g\) as a \(\mathcal{D}'\)-localization of \(f\). Then \(\beta\) induces a natural transformation \(\beta : \overline{P}_f \to \overline{P}_g\). Using \((\ast'')\), we can choose a complement \(\theta' : \overline{P}_f \to d_1\) to \(\beta\). Since \(\theta'\) is a \(q\)-coCartesian transformation of diagrams, we obtain a factorization of \(\overline{\alpha}\) as a composition

\[ \overline{P}_f \overset{\theta'}{\to} d_1 \overset{\beta}{\to} \overline{P}_{f'}. \]

We wish to prove that \(\gamma\) is an equivalence. Since \(d_1\) is a \(q\)-limit diagram (by virtue of \((\ast'')\)) and \(\overline{P}_{f'}\) is a \(q\)-limit diagram (by virtue of (I)), it will suffice to show that \(\gamma\) induces an equivalence \(d_1|K \to \overline{P}_{f'}|K\).

This follows from the fact that \(p\) factors through \(\text{Mod}^{\circ}(C)^{\circ}\).

(I4) The map \(f'\) does not belong to \(D'\). Let us identify \(f'\) with a semi-inert morphism \(C \to C'\) in \(C^{\circ}\), lying over an injective map \(j : (1) \to (k)\) in \(\text{Fin}_\ast\). Choose a splitting \(C_0' \to C' \to C'_0\) of \(C'\) corresponding to the decomposition \((k)^\circ \simeq (1)^\circ \coprod (k-1)^\circ\) induced by \(j\). This splitting can be lifted to a pair of morphisms \(f' \to f_0'\) and \(f' \to f_1'\) in \(D\). Using (I2) and (I3), we deduce that the maps \(\overline{P}(v, f') \to \overline{P}(v, f'_0)\) and \(\overline{P}(v, f') \to \overline{P}(v, f'_1)\) are inert. Since \(\mathcal{C}^{\circ}\) is an \(\infty\)-operad, to prove that the map \(\overline{P}(v, f') \to \overline{P}(v, f')\) is inert, it will suffice to show that the composite maps \(\overline{P}(v, f) \to \overline{P}(v, f'_0)\) and \(\overline{P}(v, f) \to \overline{P}(v, f'_1)\) are inert. In other words, we may replace \(f'\) by \(f'_0\) or \(f'_1\) and thereby reduce to the cases (I2) and (I3).

Now suppose that conditions (I) and (II) are satisfied; we will prove \((\ast'')\). Fix an object \(f\) in \(D\), let \(\alpha : f \to g\) be a map which exhibits \(g\) as a \(\mathcal{D}'\)-localization of \(f\), let \(\theta : \overline{P}_f \to \overline{P}_g\) be the induced natural transformation. Our construction of \(\alpha\) together with assumption (I) guarantees that \(\theta\) is split; let \(\theta' : \overline{P}_f \to d_1\) be a complement to \(\theta\). We wish to prove that \(d_1\) is a \(q\)-limit diagram. If \(f \in D'\), then \(d_1\) takes values in \(C^{\circ}_{(0)}\) and the result is obvious. We may therefore assume that \(f : C \to C'\) induces an injective map \((1) \to (k)\) in \(\text{Fin}_\ast\); choose a splitting \(C_0' \to C' \to C'_0\) corresponding to the decomposition \((k)^\circ \simeq (1)^\circ \coprod (k-1)^\circ\). This splitting lifts to a pair of maps \(\beta_0 : f \to f_0, \beta_1 : f \to f_1\) in \(D\), and we can identify \(\beta_1\) with \(\alpha : f \to g\). Using assumption (I), we see that \(\beta_0\) induces a transformation \(\overline{P}_f \to \overline{P}_{f_0}\) which is a complement to \(\theta\). We are therefore reduced to showing that \(\overline{P}_{f_0}\) is a \(q\)-limit diagram. This follows from (II), since \(f_0 : C \to C'_0\) is an equivalence in \(C\) and therefore equivalent (in \(D\)) to the identity map \(\text{id}_C\). \(\square\)
3.4.4 Colimits of Modules

Let $\mathcal{C}$ be a symmetric monoidal category, let $A$ be a commutative algebra object of $\mathcal{C}$, let $\{M_\alpha\}$ be a diagram in the category of $A$-modules, and let $M = \lim_{\alpha} M_\alpha$ be a colimit of this diagram in the underling category $\mathcal{C}$. For each index $\alpha$, we have a canonical map $A \otimes M_\alpha \to M_\alpha \to M$. These maps together determine a morphism $\lim(A \otimes M_\alpha) \to M$. If the tensor product with $A$ preserves colimits, then we can identify the domain of this map with $A \otimes M$, and the object $M \in \mathcal{C}$ inherits the structure of an $A$-module (which is then a colimit for the diagram $\{M_\alpha\}$ in the category of $A$-modules).

Our goal in this section is to obtain an $\infty$-categorical generalization of the above discussion. We first formalize the idea that “tensor products commute with colimits”.

**Definition 3.4.4.1.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad. We will say that a fibration of $\mathcal{O}$-operads $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ is a presentable $\mathcal{O}$-monoidal $\infty$-category if the following conditions are satisfied:

1. The functor $q$ is a coCartesian fibration of $\mathcal{O}$-operads.
2. The coCartesian fibration $q$ is compatible with small colimits (Definition 3.1.1.18).
3. For each $X \in \mathcal{O}$, the fiber $\mathcal{C}^\otimes_X$ is a presentable $\infty$-category.

**Theorem 3.4.4.2.** Let $\mathcal{O}^\otimes$ be a small coherent $\infty$-operad, and let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a presentable $\mathcal{O}$-monoidal $\infty$-category. Let $A \in \text{Alg}_\mathcal{O}(\mathcal{C})$ be an $\mathcal{O}$-algebra object of $\mathcal{C}$. Then the induced map $\psi : \text{Mod}_A^\mathcal{O}(\mathcal{C})^\otimes \to \mathcal{O}^\otimes$ exhibits $\text{Mod}_A^\mathcal{O}(\mathcal{C})^\otimes$ as a presentable $\mathcal{O}$-monoidal $\infty$-category.

We will deduce Theorem 3.4.4.2 from the a more general result, which can be used to construct colimits in $\infty$-categories of module objects in a wider variety of situations. The statement is somewhat complicated, since the idea that “tensor product with $A$ preserves colimits” needs to be formulated using the theory of operadic colimit diagrams described in §3.1.3.

**Theorem 3.4.4.3.** Let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a fibration of $\mathcal{O}$-operads, where $\mathcal{O}^\otimes$ is coherent. Let $K$ be an $\infty$-category and let $A \in \text{Alg}_\mathcal{O}(\mathcal{C})$ be an $\mathcal{O}$-algebra object of $\mathcal{C}$. Suppose we are given a commutative diagram

\[
\begin{array}{c}
K \\
\downarrow \downarrow \\
\text{Mod}_A^\mathcal{O}(\mathcal{C})^\otimes \\
\downarrow \psi \\
\mathcal{O}^\otimes.
\end{array}
\]

Let $\mathcal{D} = K^\otimes \times_{\mathcal{O}^\otimes} \mathcal{K}_\mathcal{O}$ and let $\mathcal{D} = K \times_{\mathcal{O}^\otimes} \mathcal{K}_\mathcal{O} \subseteq \mathcal{D}$, so that $p$ classifies a diagram $F : \mathcal{D} \to \mathcal{C}^\otimes$. Assume the following:

(i) The induced map $K^\otimes \to \mathcal{O}^\otimes$ factors through $\mathcal{O}^\act$, and carries the cone point of $K^\otimes$ to an object $X \in \mathcal{O}$.

(ii) Let $D = (v, \text{id}_X) \in \mathcal{D}$. Let $\mathcal{D}^\act_{/D}$ denote the full subcategory of $\mathcal{D} \times \mathcal{D}_{/\mathcal{D}}$ spanned by those morphisms $D' \to D$ in $\mathcal{D}$ which induce diagrams

\[
\begin{array}{ccc}
X' & \to & Y' \\
\downarrow \downarrow & & \downarrow \downarrow \\
X & \to & Y
\end{array}
\]

in $\mathcal{O}^\otimes$, where $f$ is active. Then the diagram

\[
\begin{array}{c}
\mathcal{D}^\act_{/\mathcal{D}} \\
\downarrow \\
\mathcal{D} \\
\downarrow \\
\mathcal{C}^\otimes
\end{array}
\]

\]

can be extended to a $q$-operadic colimit diagram $(\mathcal{D}^\act_{/\mathcal{D}})^\otimes \to \mathcal{C}^\otimes$ lying over the composite map

\[
(\mathcal{D}^\act_{/\mathcal{D}})^\otimes \to \mathcal{D}^\otimes_{/\mathcal{D}} \to \mathcal{D} \to K^\otimes \to \mathcal{O}^\otimes.
\]
Then:

1. Let \( p \) be an extension of \( p \) as indicated in the above diagram, corresponding to a map \( \overline{F} : \overline{D} \to C^\otimes \). Then \( \overline{p} \) is an operadic \( \psi \)-colimit diagram if and only if the following condition is satisfied:

   (*) For every object \( (v, \text{id}_X) \) as in (ii), the map
   \[
   (D^\text{act})^\circ \to D^\text{act} \to D \xrightarrow{\overline{F}} C^\otimes
   \]

   is an operadic \( q \)-colimit diagram.

2. There exists an extension \( \overline{p} \) of \( p \) satisfying condition (*).

The proof of Theorem 3.4.4.3 is rather technical, and will be given at the end of this section.

**Corollary 3.4.4.4.** Let \( p : C^\otimes \to O^\otimes \) be a fibration of \( \infty \)-operads, where \( O^\otimes \) is coherent. Let \( A \in \text{Alg}_{/O}(C) \).

Let \( f : M_0 \to M \) be a morphism in \( \text{Mod}^O_A(C)^\otimes \) be a morphism where \( M_0 \in \text{Mod}^O_A(C)^\otimes_{(0)} \) and \( M \in \text{Mod}^O_A(C) \).

The following conditions are equivalent:

1. The morphism \( f \) is classified by an operadic \( q \)-colimit diagram
   \[
   \Delta^1 \to \text{Mod}^O_A(C)^\otimes,
   \]
   where \( q : \text{Mod}^O_A(C)^\otimes \to O^\otimes \) denotes the projection.

2. Let \( F : K_0 \times_{O^\otimes} \Delta^1 \to C^\otimes \) be the map corresponding to \( f \). Then \( F \) induces an equivalence \( F(q(f)) \to F(\text{id}_{q(M)}) \).

Moreover, for every \( X \in O^\otimes \), there exists a morphism \( f : M_0 \to M \) satisfying the above conditions, with \( q(M) = X \).

**Proof.** Apply Theorem 3.4.4.3 together with the observation that the \( \infty \)-category \( D^\text{act} \) has a final object. \( \square \)

**Example 3.4.4.5.** Corollary 3.4.4.4 implies that if \( p : C^\otimes \to O^\otimes \) is a fibration of \( \infty \)-operads and \( O^\otimes \) is coherent, then \( \text{Mod}^O_A(C)^\otimes \to O^\otimes \) has units.

**Corollary 3.4.4.6.** Let \( \kappa \) be an uncountable regular cardinal. Let \( O^\otimes \) be a \( \kappa \)-small coherent \( \infty \)-operad, and let \( q : C^\otimes \to O^\otimes \) be a \( O \)-monoidal \( \infty \)-category which is compatible with \( \kappa \)-small colimits. Let \( A \in \text{Alg}_{/O}(C) \) be a \( O \)-algebra object of \( C \). Then:

1. The map \( \psi : \text{Mod}^O_A(C)^\otimes \to O^\otimes \) is a coCartesian fibration of \( \infty \)-operads which is compatible with \( \kappa \)-small colimits.

2. For each object \( X \in O \), consider the induced functor \( \phi : \text{Mod}^O_A(C)^\otimes_X \to C^\otimes_X \). Let \( K \) be a \( \kappa \)-small simplicial set and let \( \overline{p} : K^\circ \to \text{Mod}^O_A(C)^\otimes_X \) be a map. Then \( \overline{p} \) is a colimit diagram if and only if \( \phi \circ \overline{p} \) is a colimit diagram.

**Proof.** Assertion (1) follows immediately from Theorem 3.4.4.3 and Corollary 3.1.1.21. We will prove (2).

Without loss of generality, we may assume that \( K \) is an \( \infty \)-category. Let \( D = K_0 \times_{O^\otimes} \{X\} \) denote the full subcategory of \((O^\otimes)^X\) spanned by the semi-inert morphisms \( X \to Y \) in \( O^\otimes \), so that we can identify \( \overline{p} \) with a functor \( F : D \times K^\circ \to C^\otimes \). Let \( p = \overline{p}|K \). It follows from (1) (and Corollary 3.1.1.21) that \( p \) can be extended to an operadic \( \psi \)-colimit diagram in \( \text{Mod}^O_A(C)^\otimes_X \), and any such diagram is automatically a colimit diagram. From the uniqueness properties of colimit diagrams, we deduce that \( \overline{p} \) is a colimit diagram if and only if it is an operadic \( \psi \)-colimit diagram. In view of Theorem 3.4.4.3, this is true if and only if \( F \) satisfies the following condition:
Let $D = \text{id}_X \in \mathcal{D}$. Then the diagram

$$\mathcal{D}_D \times K^\circ \to \mathcal{D} \times K^\circ \xrightarrow{F} \mathcal{C}^\otimes$$

is an operadic q-colimit diagram.

Since the inclusion $\{id_D\} \to \mathcal{D}/D$ is left cofinal, condition (\star) is equivalent to the requirement that $\phi \circ p = F[\{D\}] \times K^\circ$ is an operadic q-colimit diagram. Since $\phi \circ p$ can be extended to an operadic q-colimit diagram in $\mathcal{C}_X^\otimes$ (Corollary 3.1.1.21) and any such diagram is automatically a colimit diagram in $\mathcal{C}_X^\otimes$, the uniqueness properties of colimit diagrams show that (\star) is equivalent to the requirement that $\phi \circ p$ is a colimit diagram in $\mathcal{C}_X^\otimes$. \qed

**Example 3.4.4.7.** Let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a fibration of $\infty$-operads, where $\mathcal{O}^\otimes$ is coherent. Let $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ be a $\mathcal{O}$-algebra object of $\mathcal{C}$. Then the composition $\mathcal{K}_D \downarrow \mathcal{O}^\otimes A^\otimes$ determines an object in $\text{Alg}_{/\mathcal{O}}(\text{Mod}_A^\mathcal{O}(\mathcal{C}))$, which we will denote by $\mathcal{A}$ (it is a preimage of the identity map id_A under the equivalence $\text{Alg}_{/\mathcal{O}}(\text{Mod}_A^\mathcal{O}(\mathcal{C})) \simeq \text{Alg}_{/\mathcal{O}}(\mathcal{C})A^/\mathcal{O}$ of Corollary 3.4.1.7). We can informally summarize the situation by saying that any algebra object $A \in \text{Alg}_{/\mathcal{O}}(\mathcal{C})$ can be viewed as a module over itself.

Let $0 \in \mathcal{O}^\otimes(0)$ be a zero object of $\mathcal{O}^\otimes$ and let $X \in \mathcal{O}$ be any object. Then $\mathcal{A}(0)$ is a zero object of $\text{Mod}_A^\mathcal{O}(\mathcal{C})^\otimes$, and $\mathcal{A}(X)$ is an object of $\text{Mod}_A^\mathcal{O}(\mathcal{C})_{X}^\otimes$. Any choice of map $0 \to X$ in $\mathcal{O}^\otimes$ induces a map $\eta_X : \mathcal{A}(0) \to \mathcal{A}(X)$, which is given by an edge $\overline{p} : \Delta^1 \to \text{Mod}_A^\mathcal{O}(\mathcal{C})^\otimes$. We claim that $\overline{p}$ is an operadic $\psi$-colimit diagram, where $\psi : \text{Mod}_A^\mathcal{O}(\mathcal{C})^\otimes \to \mathcal{O}^\otimes$ denotes the projection. In view of Theorem 3.4.4.3, it suffices to prove that $\overline{p}$ induces an operadic $q$-colimit diagram

$$\theta : ((\mathcal{O}^\otimes)^{0/} \times \mathcal{D}/D)^q \to \mathcal{C}^\otimes,$$

where $\mathcal{D} = \mathcal{K}_D \times \mathcal{O}^\otimes \Delta^1$ and $D$ is the object of $\mathcal{D}$ determined by the pair $(\text{id}_X, 1)$. We observe that the fiber product $(\mathcal{O}^\otimes)^{0/} \times \mathcal{D}/D$ contains a final object $C$, corresponding to the diagram

```
0 ----> X
\|     \| id
X ----> X
```

in $\mathcal{O}^\otimes$. It therefore suffices to show that the restriction $\theta_0 = \theta[\{C\}]^q \to \mathcal{C}^\otimes$ is an operadic q-colimit diagram (Remark 3.1.1.4). This is clear, since $\theta_0$ corresponds to the identity morphism $\text{id} : A(X) \to A(X)$ in $\mathcal{C}^\otimes$.

We can summarize the situation informally as follows: for every $X \in \mathcal{O}$, the map $\eta_X$ exhibits $\mathcal{A}(X) \in \text{Mod}_A^\mathcal{O}(\mathcal{C})_{X}^\otimes$ as a “unit object” with respect to the $\mathcal{O}$-operad structure on $\text{Mod}_A^\mathcal{O}(\mathcal{C})$.

We can deduce Theorem 3.4.4.2 from Theorem 3.4.4.3:

**Proof of Theorem 3.4.4.2.** In view of Corollary 3.4.4.6, it will suffice to show that for each $X \in \mathcal{O}$, the fiber $\text{Mod}_A^\mathcal{O}(\mathcal{C})_{X}^\otimes$ is an accessible $\infty$-category. Let $\mathcal{D}$ denote the full subcategory of $(\mathcal{O}^\otimes)^{X/}$ spanned by the semi-inert morphisms $f : X \to Y$, let $\mathcal{D}_0 \subseteq \mathcal{D}$ be the full subcategory spanned by those objects for which $f$ is an equivalence, and let $A' : \mathcal{D}_0 \to \mathcal{C}^\otimes$. We will say that a morphism in $\mathcal{D}$ is inert if its image in $\mathcal{O}^\otimes$ is inert. We observe that $\text{Mod}_A^\mathcal{O}(\mathcal{C})_{X}^\otimes$ can be identified with a fiber of the restriction functor

$$\phi : \text{Fun}_{\mathcal{O}^\otimes}(\mathcal{D}, \mathcal{C}^\otimes) \to \text{Fun}_{\mathcal{O}^\otimes}(\mathcal{D}_0, \mathcal{C}^\otimes),$$

where the superscript 0 indicates that we consider only those functors which carry inert morphisms in $\mathcal{D}$ (or $\mathcal{D}_0$) to inert morphisms in $\mathcal{C}^\otimes$. It follows from Corollary T.5.4.7.17 that the domain and codomain of $\phi$ are accessible $\infty$-categories and that $\phi$ is an accessible functor. Invoking Proposition T.5.4.6.6, we deduce that $\text{Mod}_A^\mathcal{O}(\mathcal{C})_{X}^\otimes$ is accessible as desired. \qed
3.4. GENERAL FEATURES OF MODULE ∞-CATEGORIES

We now turn to the proof of Theorem 3.4.4.3. We will treat assertions (1) and (2) separately. In both cases, our basic strategy is similar to that of Theorem 3.1.2.3.

Proof of Part (2) of Theorem 3.4.4.3. Let \( \mathcal{D}' \) denote the inverse image of \( \mathcal{K}_0 \) in \( \mathcal{D} \), and let \( \mathcal{D}^0 = \mathcal{D}' \cap \mathcal{D} \). Let \( \mathcal{D}' \) denote the full subcategory of \( \mathcal{D} \) spanned by \( \mathcal{D} \) together with \( \mathcal{D}' \). Note that there is a unique map \( z : \mathcal{D}' \to \Delta^2 \) such that \( z^{-1}\Delta^{(0,1)} \simeq \mathcal{D} \) and \( z^{-1}\Delta^{(1,2)} = \mathcal{D}' \). The map \( z \) is a coCartesian fibration, and therefore flat. The algebra \( A \) and the map \( F \) determine a map \( \Delta_1^2 \times \Delta^2 \mathcal{D}' \to \mathcal{C}^{\otimes} \). Using the fact that \( q \) is a categorical fibration and that the inclusion \( \Delta_1^2 \times \Delta^2 \mathcal{D}' \subseteq \mathcal{D}' \) is a categorical equivalence (Proposition B.3.2), we can find a map \( F_0 \in \text{Fun}_{\mathcal{O}^{\otimes}}(\mathcal{D}', \mathcal{C}^{\otimes}) \) compatible with \( F \) and \( A \). To complete the proof, we wish to prove that \( F_0 \) can be extended to a map \( F \in \text{Fun}_{\mathcal{O}^{\otimes}}(\mathcal{D}, \mathcal{C}^{\otimes}) \) satisfying (\(*)\) together with the following condition (which guarantees that \( F \) encodes a diagram \( K^\otimes \to \text{Mod}_A^D(\mathcal{C})^{\otimes} \)):

\[
(\ast) \quad \text{Let } \alpha : D \to D' \text{ be a morphism in } \mathcal{D} \text{ lying over the cone point of } K^\otimes \text{ whose image in } \mathcal{K}_0 \text{ is inert. Then } F' = (\alpha) \text{ is an inert morphism of } \mathcal{C}^{\otimes}.
\]

Note that, because \( \mathcal{C}^{\otimes} \) is an \( \infty \)-operad, it suffices to verify condition (\(*)\) when the object \( D' \in \mathcal{D} \) lies over \( \langle 1 \rangle \in N(\mathcal{F}\text{in}_n) \).

Let \( S \) denote the full subcategory of \( \mathcal{D} \) spanned by those objects which lie over the cone point of \( \mathcal{K}^{\otimes} \), and let \( S^0 = S \times_{\mathcal{K}_0} \mathcal{K}_0 \). Let \( \mathcal{O}_n \) denote the category \( (\mathcal{F}\text{in}_n)^{(1)}_n \) of pointed objects of \( \mathcal{F}\text{in}_n \). There is an evident forgetful functor \( S \to N(\mathcal{O}_n) \), given by the map

\[
S \subseteq \{ X \} \times_{\mathcal{O}^{\otimes}} \mathcal{K}_0 \subseteq (\mathcal{O}^{\otimes})^X \to N(\mathcal{F}\text{in}_n)^{(1)}_n \simeq N(\mathcal{O}_n).
\]

We will say that a morphism \( \alpha \) in \( \mathcal{O}_n \) is active or inert if its image in \( \mathcal{F}\text{in}_n \) is active or inert, respectively; otherwise, we will say that \( \alpha \) is neutral. Let \( \sigma \) be an \( n \)-simplex of \( N(\mathcal{O}_n) \), corresponding to a chain of morphisms

\[
\langle 1 \rangle \xrightarrow{\alpha(0)} \langle k_0 \rangle \xrightarrow{\alpha(1)} \langle k_1 \rangle \xrightarrow{\alpha(2)} \cdots \xrightarrow{\alpha(m)} \langle k_m \rangle.
\]

in the category \( \mathcal{F}\text{in}_n \). We will say that \( \sigma \) is new if it is nondegenerate and the map \( \alpha(0) \) is not null. We let \( J_\sigma \) denote the collection of integers \( j \in \{ 1, \ldots, m \} \) for which the map \( \alpha(j) \) is not an isomorphism. We will denote the cardinality of \( J_\sigma \) by \( l(\sigma) \) and refer to it as the length of \( \sigma \) (note that this length is generally smaller than \( m \)). For \( 1 \leq d \leq l(\sigma) \), we let \( J_\sigma^d \) denote the \( d \)-th element of \( J_\sigma \) and let \( \alpha_\sigma^d = \alpha(J_\sigma^d) \). We will say that \( \sigma \) is closed if \( k_m = 1 \); otherwise we will say that \( \sigma \) is open. We now partition the collection of new simplices \( \sigma \) of \( E \) into eleven groups, as in the proof of Theorem 3.1.2.3:

\[
\begin{align*}
(G'_{(1)}) & \text{ A new simplex } \sigma \text{ of } N(\mathcal{O}_n) \text{ belongs to } G'_{(1)} \text{ if it is a closed and the maps } \alpha_\sigma^i \text{ are active for } 1 \leq i \leq l(\sigma). \\
(G_{(2)}) & \text{ A new simplex } \sigma \text{ of } N(\mathcal{O}_n) \text{ belongs to } G_{(2)} \text{ if } \sigma \text{ is closed and there exists } 1 \leq k < l(\sigma) \text{ such that } \alpha_\sigma^k \text{ is inert, while } \alpha_\sigma^j \text{ is active for } k < j \leq l(\sigma). \\
(G'_{(2)}) & \text{ A new simplex } \sigma \text{ of } N(\mathcal{O}_n) \text{ belongs to } G'_{(2)} \text{ if } \sigma \text{ is closed and there exists } 1 \leq k \leq l(\sigma) \text{ such that } \alpha_\sigma^k \text{ is neutral while the maps } \alpha_\sigma^j \text{ are active for } k < j \leq l(\sigma). \\
(G_{(3)}) & \text{ A new simplex } \sigma \text{ of } N(\mathcal{O}_n) \text{ belongs to } G_{(3)} \text{ if } \sigma \text{ is closed and there exists } 1 \leq k < l(\sigma) - 1 \text{ such that } \alpha_\sigma^k \text{ is inert, the maps } \alpha_\sigma^j \text{ are active for } k < j < l(\sigma), \text{ and } \alpha_\sigma^l(\sigma) \text{ is inert.} \\
(G'_{(3)}) & \text{ A new simplex } \sigma \text{ of } N(\mathcal{O}_n) \text{ belongs to } G'_{(3)} \text{ if } \sigma \text{ is closed and there exists } 1 \leq k < l(\sigma) \text{ such that the map } \alpha_\sigma^k \text{ is neutral, the maps } \alpha_\sigma^j \text{ are active for } k < j < l(\sigma), \text{ and } \alpha_\sigma^l(\sigma) \text{ is inert.} \\
(G_{(4)}) & \text{ A new simplex } \sigma \text{ of } N(\mathcal{O}_n) \text{ belongs to } G_{(4)} \text{ if it is a closed, the maps } \alpha_\sigma^i \text{ are active for } 1 \leq i < l(\sigma), \text{ and the map } \alpha_\sigma^{l(\sigma)} \text{ is inert.} \\
(G'_{(4)}) & \text{ A new simplex } \sigma \text{ of } N(\mathcal{O}_n) \text{ belongs to } G'_{(4)} \text{ if it is an open and the maps } \alpha_\sigma^i \text{ are active for } 1 \leq i \leq l(\sigma). 
\end{align*}
\]
\( G(5) \) A new simplex \( \sigma \) of \( N(\mathcal{B}) \) belongs to \( G(5) \) if \( \sigma \) is an open and there exists \( 1 \leq k < l(\sigma) \) such that \( \alpha_k^\sigma \) is inert and \( \alpha_j^\sigma \) is active for \( k < j \leq l(\sigma) \).

\( G'(5) \) A new simplex \( \sigma \) of \( N(\mathcal{B}) \) belongs to \( G'(5) \) if \( \sigma \) is an open and there exists \( 1 \leq k \leq l(\sigma) \) such that \( \alpha_k^\sigma \) is neutral and the maps \( \alpha_j^\sigma \) are active for \( k < j \leq l(\sigma) \).

\( G(6) \) A new simplex \( \sigma \) of \( N(\mathcal{B}) \) belongs to \( G(6) \) if it is closed, has length \( \geq 2 \), and the maps \( \alpha_{l(\sigma) - 1}^\sigma \) and \( \alpha_{l(\sigma)}^\sigma \) are both inert.

\( G'(6) \) A new simplex \( \sigma \) of \( N(\mathcal{B}) \) belongs to \( G'(6) \) if it is open, has length at least 1, and the map \( \alpha_{l(\sigma)}^\sigma \) is inert.

For each integer \( m \geq 0 \), we let \( N(\mathcal{B})_m \) denote the simplicial subset spanned by those simplices which are either not new, have length \( \leq m \), or have length \( m \) and belong to one of the groups \( G(i) \) for \( 2 \leq i \leq 6 \). Let \( S(m) \) denote the inverse image \( S \times N(\mathcal{B})_m \) and let \( \mathcal{D}(m) \) denote the simplicial subset of \( \mathcal{D} \) spanned by those simplices whose intersection with \( S \) belongs to \( S(m) \). Then \( \mathcal{D}(0) = \mathcal{D}' \) is the domain of the map \( F_0 \). We will complete the proof by extending \( F_0 \) to a compatible sequence of maps \( F_m \in \text{Fun}_{\mathcal{O} \otimes} (\mathcal{E}(m), \mathcal{C}^\otimes) \), where \( F_1 \) satisfies conditions \((*)\) and \((*)\).

Let us now fix \( m > 0 \) and assume that \( F_{m-1} \) has already been constructed. We define a filtration

\[
N(\mathcal{B})_{m-1} = K(0) \subset K(1) \subset K(2) \subset K(3) \subset K(4) \subset K(5) \subset K(6) = N(\mathcal{B})_m
\]

as follows:

- We let \( K(1) \) denote the simplicial subset of \( N(\mathcal{B}) \) spanned by those simplices which either belong to \( K(0) \) or have length \((m-1)\) and belong to \( G'(1) \).

- For \( 2 \leq i \leq 6 \), we let \( K(i) \) be the simplicial subset of \( N(\mathcal{B}) \) spanned by those simplices which either belong to \( K(i-1) \), have length \( m \) and belong to \( G(i) \), or have length \( m-1 \) and belong to \( G'(i) \).

For \( 0 \leq i \leq 6 \), we let \( \overline{K}(i) \) denote the simplicial subset of \( \mathcal{E} \) spanned by those simplices whose intersection with \( E \) belongs to the inverse image of \( K(i) \). We will define maps \( f^i : \overline{K}(i) \to \mathcal{C}^\otimes \) with \( f^0 = F_{m-1} \). The construction now proceeds in six steps:

1. Assume that \( f^0 = F_{m-1} \) has been constructed; we wish to define \( f^1 \). Let \( \{ \sigma_a \}_{a \in A} \) be the collection of all simplices of \( S \) whose image in \( N(\mathcal{B}) \) have length \((m-1)\) and belong to \( G'(1) \). Choose a well-ordering of the set \( A \) such that the dimensions of the simplices \( \sigma_a \) form a (nonstrictly) increasing function of \( a \). For each \( a \in A \), let \( \mathcal{D} \leq a \) denote the simplicial subset of \( \mathcal{D} \) spanned by those simplices which either belong to \( K(0) \) or whose intersection with \( E \) is contained in \( \sigma_{a'} \) for some \( a' \leq a \), and define \( \mathcal{D} \leq a \) similarly. We construct a compatible family of maps \( f \leq a \in \text{Fun}_{\mathcal{O} \otimes} (\mathcal{D} \leq a, \mathcal{C}^\otimes) \) extending \( f^0 \), using transfinite induction on \( a \). Assume that \( f \leq a' \) has been constructed for \( a' < a \); these maps can be amalgamated to obtain a map \( f^\leq a \in \text{Fun}_{\mathcal{O} \otimes} (\mathcal{D} \leq a, \mathcal{C}^\otimes) \). Let \( Z = \mathcal{D} \times_{\mathcal{D} / \mathcal{D}} \mathcal{D}/\sigma_a \). Lemma 3.1.2.5 implies that the diagram

\[
\begin{array}{ccc}
Z \times \partial \sigma_a & \longrightarrow & \mathcal{D} \leq a \\
\downarrow & & \downarrow \\
Z \times \sigma_a & \longrightarrow & \overline{\mathcal{D}} \leq a.
\end{array}
\]

is a homotopy pushout square. Since \( q \) is a categorical fibration, it will suffice to extend the composition

\[
g_0 : Z \times \partial \sigma_a \to \mathcal{D} \leq a \to \mathcal{C}^\otimes
\]

to a map \( g \in \text{Fun}_{\mathcal{O} \otimes} (Z \sigma_a, \mathcal{C}^\otimes) \). We first treat the special case where the simplex \( \sigma_a \) is zero-dimensional (in which case we must have \( m = 1 \)). We can identify \( \sigma_a \) with an object \( D \in \mathcal{D} \). Since \( \sigma_a \) is new
3.4. General Features of Module ∞-Categories

and closed, \( D \) is equivalent to \( (v, \text{id}_X) \). Let \( Z_0 = \mathcal{D} \times_{\overline{\mathcal{D}^\text{act}}} \). It follows from assumption \((ii)\) that \( g_0 | Z_0 \) can be extended to an operadic \( q \)-colimit diagram (compatible with the projection to \( \mathcal{O}^\circ \)). Since \( Z_0 \) is a localization of \( Z \), the inclusion \( Z_0 \subseteq Z \) is left cofinal; we can therefore extend \( g_0 \) to a map \( g \in \text{Fun}_{\mathcal{O}^\circ}(\mathcal{Z} \star \sigma_a, \mathcal{C}^\circ) \), whose restriction to \( Z_0^\circ \) is an operadic \( q \)-colimit diagram. Moreover, this construction guarantees that \( f^1 \) will satisfy condition \((*)\) for the object \( D \).

Now suppose that \( \sigma_a \) is a simplex of positive dimension. We again let \( Z_0 \) denote the simplicial subset of \( Z \) spanned by those vertices which correspond to diagrams \( \sigma_a^\circ \rightarrow \mathcal{C}^\circ \) which project to a sequence of active morphisms in \( \text{N}(\mathcal{F}_{\text{Fin}}) \). The inclusion \( Z_0 \subseteq Z \) admits a left adjoint and is therefore left cofinal; it follows that the induced map \( \mathcal{C}^\circ_{(F_{m-1}|Z)/} \rightarrow \mathcal{C}^\circ_{(F_{m-1}|Z_0)/} \times_{\mathcal{O}^\circ_{(q|F_{m-1}|Z)/}} \mathcal{O}^\circ_{(q|F_{m-1}|Z)/} \) is a trivial Kan fibration. It therefore suffices to show that the restriction \( g'_0 = g_0 | (Z_0 \star \partial \sigma_a) \) can be extended to a map \( g' \in \text{Fun}_{\mathcal{O}^\circ}(Z_0 \star \sigma_a, \mathcal{C}^\circ) \) . Let \( D \) denote the initial vertex of \( \sigma \). In view of Proposition 3.1.1.7, it will suffice to show that the restriction \( g'_0 | (Z_0 \star \{D\}) \) is an operadic \( q \)-colimit diagram. Since the inclusion \( \{D\} \subseteq \sigma_a \) is left anodyne, the projection map \( Z_0 \rightarrow \mathcal{D}_D^\text{act} = \mathcal{D} \times_{\overline{\mathcal{D}^\text{act}}} \mathcal{D}^\text{act}_D \) is a trivial Kan fibration. It will therefore suffice to show that \( F_{m-1} \) induces an operadic \( q \)-colimit diagram \( \delta : (\mathcal{D}_D^\text{act})^\circ \rightarrow \mathcal{O}^\circ \).

The object \( D \in \overline{\mathcal{D}} \) determines a semi-inert morphism \( \gamma : X \rightarrow Y \) in \( \mathcal{O}^\circ \). Since \( \sigma_a \) is new, this morphism is not null and therefore determines an equivalence \( Y \simeq Y_0 \oplus X \). Let \( X \) denote the full subcategory of \( \mathcal{D}_D^\text{act} \) spanned by those objects corresponding to diagrams

\[
\begin{array}{ccc}
X' & \longrightarrow & Y' \\
\downarrow & & \downarrow \phi \\
X & \longrightarrow & Y_0 \oplus X
\end{array}
\]

where the active morphism \( \phi \) exhibits \( Y' \) as a sum \( Y_0' \oplus Y_1' \), where \( Y_0' \simeq Y_0 \) and \( Y_1' \rightarrow X \) is an active morphism. The inclusion \( X \subseteq \mathcal{D}_D^\text{act} \) admits a left adjoint, and is therefore left cofinal. Let \( D_0 = (v, \text{id}_X) \in \overline{\mathcal{D}} \), so that the operation \( \bullet \mapsto Y_0 \oplus \bullet \) determines an equivalence \( \mathcal{D}_D^\text{act} \rightarrow X \). It therefore suffices to show that the composite map

\[
(\mathcal{D}_D^\text{act})^\circ \xrightarrow{Y_0^\circ} X^\circ \subseteq (\mathcal{D}_D^\text{act})^\circ \xrightarrow{\delta} \mathcal{O}^\circ
\]

is an operadic \( q \)-colimit diagram. Using condition \((*)\), we can identify this map with the composition

\[
(\mathcal{D}_D^\text{act})^\circ \longrightarrow \mathcal{O}^\circ \xrightarrow{A(\{v\})^\circ} \mathcal{C}^\circ,
\]

which is an operadic \( q \)-colimit diagram by virtue of \((*)\).

2. We now assume that \( f^1 \) has been constructed. Since \( q \) is a categorical fibration, to produce the desired extension \( f^2 \) of \( f^1 \) it is sufficient to show that the inclusion \( \overline{\mathcal{K}}(1) \subseteq \overline{\mathcal{K}}(2) \) is a categorical equivalence. For each simplex \( \sigma \) of \( \text{N}(\mathcal{J}) \) of length \( m \) belonging to \( G(2) \), let \( k(\sigma) < m \) be the integer such that \( \alpha_{k(\sigma)}^\circ \) is inert while \( \alpha_j^\circ \) is active for \( k(\sigma) < j \leq m \). We will say that \( \sigma \) is good if \( \alpha_{k(\sigma)}^\circ \) induces a map \( \langle p \rangle \rightarrow \langle p' \rangle \) in \( \mathcal{F}_{\text{Fin}} \), whose restriction to \( \langle \alpha_j^\circ \rangle^{-1} \langle p' \rangle^\circ \) is order preserving. Let \( J = \mathcal{K}^\circ \times_{\mathcal{F}_{\text{Fin}}(\{v\})} \mathcal{F}_{\text{Fin}}(\mathcal{A}^1, \mathcal{N}(\mathcal{F}_{\text{Fin}})) \), so that we can identify \( \mathcal{N}(\mathcal{J}) \) with the simplicial subset \( J \times_{\mathcal{K}^\circ} \{v\} \). Let \( \{\sigma_a\}_{a \in A} \) be the collection of all nondegenerate simplices of \( J \) such that the intersection \( \sigma_a^\circ \cap \mathcal{N}(\mathcal{J}) \) is nonempty and good. For each \( a \in A \), let \( k_a = k(\sigma^a) \) and \( j_a = j_k^a \). Choose a well-ordering of \( A \) with the following properties:

- The map \( a \mapsto k_a \) is a (nonstrictly) increasing function of \( a \in A \).
- For each integer \( k \), the dimension of the simplex \( \sigma_a \) is a nonstrictly increasing function of \( a \in A_k = \{a \in A : k_a = k\} \).

\section{Algebras and Modules Over $\infty$-Operads}

- Fix integers $k, d \geq 0$, and let $A_{k,d}$ be the collection of elements $a \in A_k$ such that $\sigma_a$ has dimension $d$. The map $a \mapsto j_a$ is a nonstrictly increasing function on $A_{k,d}$.

Let $J_{<0}$ be the collection of those simplices of $J$ whose intersection with $N(J)$ belongs to $K(1)$. For each $a \in A$, let $J_{<a}$ denote the simplicial subset of $J$ generated by $J_0$ together with the simplices the simplices $\{\sigma_{a'}\}_{a' < a}$, and define $J_{<a}$ similarly. The inclusion $K(1) \subseteq K(2)$ can be obtained as a transfinite composition of inclusions

\[ i_a : \overline{D} \times J J_{<a} \rightarrow \overline{D} \times J J_{<a}. \]

Each $i_a$ is a pushout of an inclusion $i'_a : \overline{D} \times J J_{<a} \rightarrow \overline{D} \times J J_{<a}$, where $\sigma_a^0 \subseteq \sigma_a$ denotes the inner horn obtained by removing the interior of $\sigma_a$ together with the face opposite the $j_a$th vertex of $\sigma_a'$, and therefore a categorical equivalence by Lemma 2.4.4.6.

(3) To find the desired extension $f^3$ of $f^2$, it suffices to show that the inclusion $K(2) \subseteq K(3)$ is a categorical equivalence. This follows from the argument given in step (2).

(4) Let $\{\sigma_a\}_{a \in A}$ denote the collection of all nondegenerate simplices $\sigma$ of $\overline{D}$ with the property that $\sigma \cap S$ is nonempty and projects to a simplex of $N(J)$ of length $m - 1$ which belongs to $G'_q$. Choose a well-ordering of $A$ having the property that the dimensions of the simplices $\sigma_a$ form a (nonstrictly) increasing function of $a$. For each $a \in A$ let $D_a \in \overline{D}$ denote the final vertex of $\sigma_a$ and let $Z_a$ denote the full subcategory of $S \times_\pi D_{\sigma_a}$ spanned by those objects for which the underlying map $D_a \rightarrow D$ induces an inert morphism $\langle m \rangle \rightarrow \langle 1 \rangle$ in $N(\text{Fin}_*)$. We have a canonical map $t_a : \sigma_a * Z_a \rightarrow \overline{D}$. For each $a \in A$, let $\overline{C}_{<a} \subseteq \overline{D}$ denote the simplicial subset generated by $K(3)$ together with the image of $t_a'$ for all $a' \leq a$, and define $\overline{D}_{<a}$ similarly. Then $K(4) = \bigcup_{a \in A} \overline{C}_{<a}$ and that for each $a \in A$ Lemma 3.1.2.5 implies that we have a homotopy pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\partial \sigma_a * Z_a & \rightarrow & \overline{D}_{<a} \\
\downarrow & & \downarrow \\
\sigma_a * Z_a & \rightarrow & \overline{D}_{<a}.
\end{array}
\]

To construct $f^4$, we are reduced to the problem of solving a sequence of extension problems of the form

\[
\begin{array}{ccc}
\partial \sigma_a * Z_a & \xrightarrow{g_0} & C^\otimes \\
\downarrow & \downarrow & \uparrow q \\
\sigma_a * Z_a & \xrightarrow{g} & C^\otimes.
\end{array}
\]

Note that $Z_a$ decomposes a disjoint union of $\infty$-categories $\coprod_{1 \leq i \leq m} Z_{a,i}$ (where $(m)$ denotes the image of $D_a$ in $N(\text{Fin}_*)$). Each of the $\infty$-categories $Z_{a,i}$ has an initial object $B_i$, given by any map $\sigma_a \xrightarrow{\{D_i\}} C^\otimes$ which induces an inert morphism $D_a \rightarrow D_i$ covering $\rho^i : \langle m \rangle \rightarrow \langle 1 \rangle$. Let $h : Z_a \rightarrow C^\otimes$ be the map induced by $g_0$, and let $h'$ be the restriction of $h$ to the discrete simplicial set $Z_{a,i} = \{B_i\}_{1 \leq i \leq m}$. Since the inclusion $Z_{a,i} \rightarrow Z_a$ is left anodyne, we have a trivial Kan fibration $C^\otimes \rightarrow C^\otimes_{h'} \times_{C^\otimes} C^\otimes_{h'}$. Unwinding the definitions, we are reduced to the lifting problem depicted in the diagram

\[
\begin{array}{ccc}
\partial \sigma_a * Z_a' & \xrightarrow{g_h} & C^\otimes \\
\downarrow & \downarrow & \uparrow q \\
\sigma_a * Z_a' & \xrightarrow{\pi} & C^\otimes.
\end{array}
\]
If the dimension of \( \sigma_a \) is positive, then it suffices to show that \( g'_0 \) carries \( \{ D_a \} \star Z'_a \) to a \( q \)-limit diagram in \( \mathcal{C}^\otimes \). Let \( q' \) denote the canonical map \( \mathcal{O}^\otimes \to N(\text{Fin}_*) \). In view of Proposition \( T.4.3.1.5 \), it suffices to show that \( g'_0 \) carries \( \{ D_a \} \star Z'_a \) to a \( (q' \circ q) \)-limit diagram and that \( q \circ g'_0 \) carries \( \{ D_a \} \star Z'_a \) to a \( q \)-limit diagram. The first of these assertions follows from (\( * \)) and from the fact that \( \mathcal{O}^\otimes \) is an \( \infty \)-operad, and the second follows by the same argument (since \( q \) is a map of \( \infty \)-operads).

It remains to treat the case where \( \sigma_a \) is zero dimensional (in which case we have \( m = 1 \)). Since \( \mathcal{C}^\otimes \) is an \( \infty \)-operad, we can solve the lifting problem depicted in the diagram

\[
\begin{array}{ccc}
\partial \sigma_a \star Z'_a & \xrightarrow{g'_0} & \mathcal{O}^\otimes \\
\downarrow & & \downarrow \\
\sigma_a \star Z'_a & \xrightarrow{q'_{oq}} & N(\text{Fin}_*)
\end{array}
\]

in such a way that \( g'' \) carries edges of \( \sigma_a \star Z'_a \) to inert morphisms in \( \mathcal{C}^\otimes \). Since \( q \) is an \( \infty \)-operad map, it follows that \( q \circ g'' \) has the same property. Since \( \mathcal{O}^\otimes \) is an \( \infty \)-operad, we conclude that \( q \circ g'' \) and \( g' \) are both \( q' \)-limit diagrams in \( \mathcal{O}^\otimes \) extending \( q \circ g'_0 \), and therefore equivalent to one another via an equivalence which is fixed on \( Z'_a \) and compatible with the projection to \( N(\text{Fin}_*) \). Since \( q \) is a categorical fibration, we can lift this equivalence to an equivalence \( g'' \simeq g' \), where \( g' : \sigma_a \star Z'_a \to \mathcal{C}^\otimes \) is the desired extension of \( g'_0 \). We note that this construction ensures that condition (\( * \)) is satisfied.

(5) To find the desired extension \( f^5 \) of \( f^4 \), it suffices to show that the inclusion \( \overline{K}(4) \subseteq \overline{K}(5) \) is a categorical equivalence. This again follows from the argument given in step (2).

(6) The verification that \( f^5 \) can be extended to a map \( f^6 : \overline{K}(6) \to \mathcal{C}^\otimes \) proceeds as in step (4), but is slightly easier (since \( G'_6(6) \) contains no 0-simplices).

Proof of Part (1) of Theorem 3.4.4.3. We wish to show that a diagram \( \overline{p} : K^\circ \to \text{Mod}^{G}_A(\mathcal{C})^\otimes \) satisfies condition (\( * \)) if and only if it is an operadic \( \psi \)-colimit diagram. We will prove the "only if" direction; the converse will follow from assertion (2) together with the uniqueness properties of operadic colimit diagrams. Fix an object \( Y \in \text{Mod}^{G}_A(\mathcal{C})^\otimes \) lying over \( Y \in \mathcal{O}^\otimes \) and let \( \overline{p}_Y : K^\circ \to \text{Mod}^{G}_A(\mathcal{C})^\otimes \); given by the composition

\[
K^\circ \xrightarrow{\overline{p}} \text{Mod}^{G}_A(\mathcal{C})^\otimes \xrightarrow{\overline{p}_Y} \text{Mod}^{G}_A(\mathcal{C})^\otimes;
\]

we must show that \( \overline{p}_Y \) is a weak \( \psi \)-operadic colimit diagram. Unwinding the definitions, we must show that for \( n > 0 \), every lifting problem of the form

\[
\begin{array}{ccc}
\partial K \star \Delta^n & \xrightarrow{p'} & \text{Mod}_A(\mathcal{C})^\otimes \\
\downarrow & & \downarrow \\
K \star \Delta^n & \xrightarrow{p_0} & \mathcal{O}^\otimes
\end{array}
\]

admits a solution, provided that \( p' \mid K \star \{0\} = \overline{p}_Y \) and \( p_0 \) carries \( \Delta^{(1,\ldots,n)} \) into \( \mathcal{O} \subseteq \mathcal{O}^\otimes \).

Let \( \overline{\mathcal{F}} \) denote the fiber product \( (K \star \Delta^n) \times_{\mathcal{O}^\otimes} \mathcal{X}_\mathcal{O} \), let \( \overline{\mathcal{F}}^0 = (K \star \Delta^n) \times_{\mathcal{O}^\otimes} \mathcal{K}_\mathcal{O} \). Let \( \overline{\mathcal{F}}^1 \) denote the full subcategory of \( \overline{\mathcal{F}} = (K \star \{0\}) \times_{\mathcal{O}^\otimes} \mathcal{X}_\mathcal{O} \) spanned by \( \mathcal{F} = K \times_{\mathcal{O}^\otimes} \mathcal{K}_\mathcal{O} \) together with those vertices of \( \{0\} \times_{\mathcal{O}^\otimes} \mathcal{K}_\mathcal{O} \) which correspond to semi-inert morphisms \( X \odot Y \to Y' \) in \( \mathcal{O}^\otimes \) such that the underlying map in \( \text{Fin}_* \) is not injective. Let \( \mathcal{F}' \) denote the full subcategory of \( \overline{\mathcal{F}} \) spanned by \( \overline{\mathcal{F}}^1 \) together with \( \overline{\mathcal{F}}^0 \). Note that there is a unique map \( z : \mathcal{F}' \to \Delta^2 \) such that \( z^{-1} \Delta^{(0,1)} = \overline{\mathcal{F}}^1 \) and \( z^{-1} \Delta^{(1,2)} = \overline{\mathcal{F}}^0 \). The map \( z \) is a coCartesian fibration and therefore flat. The algebra \( A \) and the map \( \overline{p} \) determine a map \( A^\otimes(2) \times_{\Delta^2} \mathcal{F}' \to \mathcal{C}^\otimes \). Using the fact that
q is a categorical fibration and that the inclusion $\Lambda^2_1 \times \Delta^2 \subseteq \mathcal{T}' \subseteq \mathcal{T}$ is a categorical equivalence (Proposition B.3.2), we can find a map $F'' \in \text{Fun}_\otimes^\circ(\mathcal{T}', \mathcal{O})$ compatible with $F$ and $A$. Amalgamating $F_0$ with the map determined by $p'$, we obtain a map $F'' \in \text{Fun}_\otimes(\mathcal{T}'', \mathcal{O})$ where

$$\mathcal{T}'' = \left( (K \star \Delta^n) \times \mathcal{O} \otimes \mathcal{K}_\otimes \right) \coprod_{\mathcal{T'}} \mathcal{T}' \subseteq \mathcal{T}.$$  

To complete the proof, we wish to prove that $F''$ can be extended to a map $\overline{F} \in \text{Fun}_\otimes(\mathcal{T}, \mathcal{O})$.

Let $T$ denote the fiber product $\mathcal{T} \times_{K \star \Delta^n} \Delta^n$ and let $T^0 = T \times_{\mathcal{K}_\otimes} \mathcal{K}_\otimes^0$. The diagram $K \star \Delta^n \to \mathcal{O}$ determines a map $\Delta^n \to N(\mathcal{F}_\text{in})$, corresponding to a decomposable sequence of active morphisms

$$\langle j+1 \rangle \to \langle 1 \rangle \simeq \langle 1 \rangle \simeq \cdots \simeq \langle 1 \rangle.$$  

Here $\langle j \rangle$ corresponds to the image of $Y$ in $N(\mathcal{F}_\text{in})$. Let $J$ denote the fiber product category $[n] \times \text{Fun}(\{0\}, \mathcal{F}_\text{in})$. There is an evident forgetful functor $T \to N(\mathcal{F})$, whose second projection is given by the composition

$$T \subseteq \Delta^n \times \mathcal{O} \otimes \mathcal{K}_\otimes \to \text{Fun}(\Delta^1, \mathcal{O}^\otimes) \to N(\text{Fun}(\{1\}, \mathcal{J})).$$  

We will say that a morphism $\alpha$ in $\mathcal{J}$ is active or inert if its image in $\mathcal{F}_\text{in}$ is active or inert, respectively; otherwise, we will say that $\alpha$ is neutral. Let $\sigma$ be an m-simplex of $N(\mathcal{J})$. We will say that $\sigma$ is new if $\sigma$ is nondegenerate, the map $\sigma \to \Delta^n$ is surjective, and the semi-inert morphism $(j+1) \to \langle k_0 \rangle$ given by the first vertex of $\sigma$ is injective. Every such simplex determines a chain of morphisms

$$\langle k_0 \rangle \xrightarrow{\alpha_1} \langle k_1 \rangle \xrightarrow{\alpha_2} \cdots \xrightarrow{\alpha_m} \langle k_m \rangle.$$  

in the category $\mathcal{F}_\text{in}$. We let $J_\sigma$ denote the collection of integers $j \in \{1, \ldots, m\}$ for which the map $\alpha(j)$ is not an isomorphism. We will denote the cardinality of $J_\sigma$ by $l(\sigma)$ and refer to it as the length of $\sigma$ (note that this length is generally smaller than $m$). For $1 \leq d \leq l(\sigma)$, we let $j_\sigma^d$ denote the $d$th element of $J_\sigma$ and set $\alpha_\sigma^d = \alpha(j_\sigma^d)$. We will say that $\sigma$ is closed if $k_m = 1$; otherwise we will say that $\sigma$ is open. As in the proof of assertion (2) (and the proof of Theorem 3.1.2.3), we partition the new simplices of $N(\mathcal{J})$ into eleven groups $\{G(i)\}_{2 \leq i \leq 6} \cup \{G(i)\}_{1 \leq i \leq 6}$.

For each $m \geq 0$, we let $N(\mathcal{J})_m$ denote the simplicial subset spanned by those simplices which are either not new, have length $\leq m$, or have length $m$ and belong to one of the groups $G(i)$ for $2 \leq i \leq 6$. Let $T(m)$ denote the inverse image $T \times_{N(\mathcal{J})} N(\mathcal{J})_m$ and let $\overline{T}(m)$ denote the simplicial subset of $\overline{T}$ spanned by those simplices whose intersection with $E$ belongs to $E(m)$. Then $\overline{T}(0) = \mathcal{T}''$ is the domain of the map $F'' = F_0''$. We will complete the proof by extending $F''_0$ to a compatible sequence of maps $F''_m \in \text{Fun}_\otimes(\overline{T}(m), \mathcal{O})$.

Fix $m > 0$ and assume that $F''_{m-1}$ has already been constructed. We define a filtration

$$N(\mathcal{J})_{m-1} = K(0) \subseteq K(1) \subseteq K(2) \subseteq K(3) \subseteq K(4) \subseteq K(5) \subseteq K(6) = N(\mathcal{J})_m$$  

as follows:

- We let $K(i)$ denote the simplicial subset of $N(\mathcal{J})$ spanned by those simplices which either belong to $K(0)$ or have length $(m - 1)$ and belong to $G(i)$.

- For $2 \leq i \leq 6$, we let $K(i)$ be the simplicial subset of $N(\mathcal{J})$ spanned by those simplices which either belong to $K(i-1)$, have length $m$ and belong to $G(i)$, or have length $m - 1$ and belong to $G(i)$.

For $0 \leq i \leq 6$, we let $\overline{K}(i)$ denote the simplicial subset of $\overline{E}$ spanned by those simplices whose intersection with $E$ belongs to the inverse image of $K(i)$. We will define maps $f^i : \overline{K}(i) \to \mathcal{O}^\otimes$ with $f^0 = F''_{m-1}$. We will explain how to construct $f^i$ from $f^0$; the remaining steps can be handled as in our proof of part (2).

Assume that $f^0 = F''_{m-1}$ has been constructed; we wish to define $f^i$. Let $\{\sigma_a\}_{a \in A}$ be the collection of all simplices of $E$ whose image in $N(\mathcal{J})$ have length $(m - 1)$ and belong to $G(i)$. Choose a well-ordering of the set
A such that the dimensions of the simplices \( \sigma_a \) form a (nonstrictly) increasing function of \( a \). For each \( a \in A \), let \( \mathcal{T}_{\leq a} \) denote the simplicial subset of \( \mathcal{T} \) spanned by those simplices which either belong to \( \mathcal{K}(0) \) or whose intersection with \( E \) is contained in \( \sigma_{a'} \) for some \( a' \leq a \), and define \( \mathcal{T}_{< a} \) similarly. We construct a compatible family of maps \( f_{\leq a} \in \text{Fun}_{\sigma_0}(\mathcal{T}_{\leq a}, \mathcal{C}^\otimes) \) extending \( f_0^\prime \), using transfinite induction on \( a \). Assume that \( f_{\leq a'} \) has been constructed for \( a' < a \); these maps can be amalgamated to obtain a map \( f_{< a} \in \text{Fun}_{\sigma_0}(\mathcal{T}_{< a}, \mathcal{C}^\otimes) \). Let \( \mathcal{T} = \mathcal{T} \times_{K \times \Delta^n} K \), and let \( Z = \mathcal{T} \times_{\mathcal{T}} /_{\sigma_a} \). Lemma 3.1.2.5 implies that we have a homotopy pushout diagram of simplicial sets

\[
\begin{array}{ccc}
Z \times \partial \sigma_a & \rightarrow & \mathcal{T}_{< a} \\
\downarrow & & \downarrow \\
Z \times \sigma_a & \rightarrow & \mathcal{T}_{\leq a},
\end{array}
\]

where the vertical maps are cofibrations. It will therefore suffice to extend the composition

\[
g_0 : Z \times \partial \sigma_a \rightarrow \mathcal{T}_{< a} \rightarrow f_{< a} \rightarrow \mathcal{C}^\otimes
\]
to a map \( g \in \text{Fun}_{\sigma_0}(Z \times \sigma_a, \mathcal{C}^\otimes) \).

Note that \( \sigma_a \) necessarily has positive dimension (since the map \( \sigma_a \rightarrow \Delta^n \) is surjective). Let \( Z_0 \) denote the simplicial subset of \( Z \) spanned by those vertices which correspond to diagrams \( \sigma_{a_0} \rightarrow \mathcal{C}^\otimes \) which project to a sequence of active morphisms in \( \text{N}(\mathcal{F}_{\text{fin}}) \). The inclusion \( Z_0 \subseteq Z \) admits a left adjoint and is therefore left cofinal; it follows that the induced map

\[
\mathcal{C}^\otimes_{(F_{m-1}|Z)/(F_{m-1}|Z_0) / \times \mathcal{C}^\otimes_{(qF_{m-1}|Z_0)/(qF_{m-1}|Z)}}
\]
is a trivial Kan fibration. It therefore suffices to show that the restriction \( g'_0 = g_0|_{(Z_0 \times \partial \sigma_a)} \) can be extended to a map \( g' \in \text{Fun}_{\sigma_0}(Z_0 \times \sigma_a, \mathcal{C}^\otimes) \). Let \( D \) denote the initial vertex of \( \sigma \). In view of Proposition 3.1.1.7, it will suffice to show that the restriction \( g'_0|_{(Z_0 \times \{D\})} \) is an operadic \( q \)-colimit diagram. Since the inclusion \( \{D\} \subseteq \sigma_a \) is left anodyne, the projection map \( Z_0 \rightarrow \mathcal{T}^\text{act}_{/D} = \mathcal{T} \times_{K \times \Delta^n} K \) is a trivial Kan fibration. It will therefore suffice to show that \( F_{m-1} \) induces an operadic \( q \)-colimit diagram \( \delta : (\mathcal{T}^\text{act}_{/D})^\triangleright \rightarrow \mathcal{C}^\otimes \).

The object \( D \in \mathcal{T} \) determines a semi-inert morphism \( \gamma : X \oplus Y \rightarrow Y'' \) in \( \mathcal{O}^\otimes \). Since \( \sigma_a \) is new, the underlying morphism in \( \text{N}(\mathcal{F}_{\text{fin}}) \) is injective, so that \( \gamma \) induces an equivalence \( Y'' \simeq X \oplus Y \oplus Y'' \), for some \( Y'' \in \mathcal{O}^\otimes \). Let \( X \) denote the full subcategory of \( \mathcal{T}^\text{act}_{/D} \) spanned by those objects corresponding to diagrams

\[
\begin{array}{ccc}
X_0 \oplus Y & \rightarrow & Y_0 \\
\downarrow \phi & & \downarrow \\
X \oplus Y & \rightarrow & X \oplus Y \oplus Y''
\end{array}
\]

where the active morphism \( \phi \) exhibits \( Y_0 \) as a sum \( Y_0' \oplus Y_0'' \), where \( Y_0' \rightarrow X \) is an active morphism and \( Y_0'' \simeq Y \oplus Y'' \). The inclusion \( X \subseteq \mathcal{T}^\text{act}_{/D} \) admits a left adjoint, and is therefore left cofinal.

Let \( D_0 \in \mathcal{T} = (K \times \{0\}) \times_{K} \mathcal{K}_0 \) be the object corresponding to \( \text{id}_X \). The operation \( \bullet \mapsto \bullet \oplus Y \oplus Y'' \) determines an equivalence of \( \infty \)-categories \( \mathcal{T}^\text{act}_{/D_0} \rightarrow X \). It therefore suffices to show that the composite map

\[
(\mathcal{T}^\text{act}_{/D_0})^\triangleright \rightarrow X^\otimes \subseteq (\mathcal{T}^\text{act}_{/D})^\triangleright \rightarrow \mathcal{C}^\otimes
\]
is an operadic \( q \)-colimit diagram. This composition can be identified with the map

\[
(\mathcal{T}^\text{act}_{/D_0})^\triangleright \rightarrow \mathcal{C}^\otimes \xrightarrow{A(Y\oplus Y'')} \mathcal{C}^\otimes,
\]

which is an operadic \( q \)-colimit diagram by virtue of our assumption that \( \mathcal{P} \) satisfies condition \((*)\). \( \square \)
Chapter 4

Associative Algebras and Their Modules

Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category. For any $\infty$-operad $O^\otimes$, we can consider the $\infty$-category $\text{Alg}_O(\mathcal{C})$ of $O$-algebra objects of $\mathcal{C}$ (Definition 2.1.2.7), which we studied in Chapter 3. In this chapter, we will specialize the general theory to obtain a notion of associative algebra in $\mathcal{C}$, which we study in depth. We begin in §4.1 by introducing the associative $\infty$-operad, which we denote by $\text{Ass}^\otimes$. By definition, an associative algebra object of a symmetric monoidal $\infty$-category $\mathcal{C}$ is a map of $\infty$-operads $\text{Ass}^\otimes \to \mathcal{C}^\otimes$.

Many basic facts about associative algebras can be deduced from the general formalism developed in Chapters 2 and 3. However, there are some facets of the theory which are special to the associative case. For example, if $A$ is an associative algebra object of a symmetric monoidal $\infty$-category $\mathcal{C}$, then there is an associated theory of left modules over $A$ (and a formally dual theory of right modules over $A$). The collection of all left $A$-modules is naturally organized into an $\infty$-category, which we denote by $\text{LMod}_A(\mathcal{C})$. We will undertake a detailed study of this $\infty$-category in §4.2.

If $A$ is an associative algebra object of an $\infty$-category $\mathcal{C}$, we can use the general formalism of §3.3 to obtain a different notion of $A$-module: namely, an $\text{Ass}$-module over $A$ (see Definition 3.3.3.8). The collection of $\text{Ass}$-modules over $A$ form an $\infty$-category $\text{Mod}^\text{Ass}(\mathcal{C})$. There is a forgetful functor $\text{Mod}^\text{Ass}(\mathcal{C}) \to \text{LMod}_A(\mathcal{C})$, which is usually not an equivalence of $\infty$-categories: every object $M \in \text{Mod}^\text{Ass}(\mathcal{C})$ is equipped not only with a left action of the algebra $A$, but also with a (commuting) right action of $A$. In §4.3, we will describe the situation formally by introducing the notion of a bimodule object of $\mathcal{C}$. For every pair of associative algebra objects $A$ and $B$, we will define an $\infty$-category $\text{BMod}_A(B)(\mathcal{C})$, which is equipped with forgetful functors

$$\text{LMod}_A(\mathcal{C}) \leftarrow \text{BMod}_B(\mathcal{C}) \to \text{RMod}_B(\mathcal{C}).$$

We will show that there is a canonical equivalence of $\infty$-categories $\theta : \text{Mod}^\text{Ass}_A(\mathcal{C}) \simeq \text{BMod}_A(\mathcal{C})$ (Theorem 4.4.1.28). In fact, we will prove something a little stronger: under some mild hypotheses, the functor $\theta$ is an equivalence of monoidal categories. Here the tensor product on $\text{Mod}^\text{Ass}_A(\mathcal{C})$ is determined by the general formalism of Chapter 3, and the tensor product on $\text{BMod}_A(\mathcal{C})$ is given as a special case of a more general relative tensor product

$$\text{BMod}_B(\mathcal{C}) \times_B \text{BMod}_C(\mathcal{C}) \to \text{BMod}_C(\mathcal{C})$$

which we will study in §4.4. In §4.6, we will use relative tensor products to develop a theory of duality for bimodule objects of $\mathcal{C}$.

Suppose now that $A$ is a commutative algebra object of $\mathcal{C}$. In this case, the general formalism of Chapter 3 determines an $\infty$-category $\text{Mod}_A(\mathcal{C}) = \text{Mod}^\text{Comm}_A(\mathcal{C})$ of Comm-modules over $A$. The map of $\infty$-operads $\text{Ass}^\otimes \to \text{Comm}^\otimes$ determines a forgetful functor $\text{Mod}_A(\mathcal{C}) \to \text{Mod}^\text{Ass}_A(\mathcal{C})$, which fits into a commutative
In §4.5, we will show that the diagonal arrows in this diagram are categorical equivalences (Proposition 4.5.1.4). In other words, if \( A \) is a commutative algebra object of \( \mathcal{C} \), then the \( \infty \)-categories of left, right, and Comm modules over \( A \) are canonically equivalent. Under some mild hypotheses, each of these \( \infty \)-categories admits a symmetric monoidal structure, given by the relative tensor product over \( A \) (Theorem 4.5.2.1).

Let \( \mathcal{C} \) be a monoidal category containing an object \( X \). We say that \( X \) is right dualizable if there exists another object \( X^\vee \) (called the right dual of \( X \)) and a pair of maps
\[
c : 1 \to X \otimes X^\vee \
e : X^\vee \otimes X \to 1
\]
(where \( 1 \) denotes the unit object of \( \mathcal{C} \)) for which the composite maps
\[
X \xrightarrow{c \otimes \text{id}} X \otimes X^\vee \otimes X \xrightarrow{\text{id} \otimes e} X
\]
\[
X^\vee \xrightarrow{\text{id} \otimes e} X^\vee \otimes X \otimes X^\vee \xrightarrow{e \otimes \text{id}} X^\vee
\]
are the identity on \( X \) and \( X^\vee \), respectively. If \( \mathcal{C} \) is a monoidal \( \infty \)-category, then we say that an object \( X \in \mathcal{C} \) is right dualizable if it is right dualizable when regarded as an object of the homotopy category \( \text{hC} \). In §4.6, we will make a detailed study of duality in the setting of monoidal \( \infty \)-categories (and, more generally, duality for bimodule objects of monoidal \( \infty \)-categories).

For any \( \infty \)-category \( \mathcal{E} \), the \( \infty \)-category of functors \( \text{Fun}(\mathcal{E}, \mathcal{E}) \) admits a monoidal structure (given by composition of functors). For every algebra object \( T \in \text{Alg}(\text{Fun}(\mathcal{E}, \mathcal{E})) \), one can consider an \( \infty \)-category \( \text{LMod}_T(\mathcal{E}) \) of left \( T \)-modules in \( \mathcal{E} \). This \( \infty \)-category is related to \( \mathcal{E} \) by a pair of adjoint functors
\[
\mathcal{E} \xleftarrow{F} \text{LMod}_T(\mathcal{E}).
\]
We will say that an adjunction is monadic if it is of this form. In §4.7, we will prove an \( \infty \)-categorical version of the Barr-Beck monadicity theorem, which gives necessary and sufficient conditions for an arbitrary adjunction
\[
\mathcal{E} \xleftarrow{F} \mathcal{D}
\]
to be monadic.

Let \( \mathcal{C} \) be a monoidal \( \infty \)-category, which we will regard as an associative algebra object of \( \text{Cat}_\infty \). For every associative algebra object \( A \in \text{Alg}(\mathcal{C}) \), the \( \infty \)-category \( \text{RMod}_A(\mathcal{C}) \) of right \( A \)-modules can be regarded as a left \( \mathcal{C} \)-module in \( \text{Cat}_\infty \). In §4.8, we make a detailed study of the construction
\[
\text{Alg}(\mathcal{C}) \to \text{LMod}_C(\text{Cat}_\infty) \\
A \mapsto \text{RMod}_A(\mathcal{C}),
\]
which will play an important role in our analysis of the little cubes \( \infty \)-operads \( \mathcal{E}_k^\circ \) of Chapter 5.
4.1 Associative Algebras

Let \( \mathcal{C} \) be a monoidal category. Then one can consider *associative algebra objects* of \( \mathcal{C} \): that is, objects \( A \in \mathcal{C} \) equipped with a unit map \( u : 1 \to A \) and a multiplication map \( m : A \times A \to A \) such that the diagrams

\[
\begin{array}{ccc}
1 \otimes A & \xrightarrow{u \otimes \text{id}} & A \otimes A \\
\downarrow m & & \downarrow m \\
A & & A
\end{array}
\]

\[
\begin{array}{ccc}
A \otimes 1 & \xrightarrow{\text{id} \otimes u} & A \otimes A \\
\downarrow m & & \downarrow m \\
A & & A
\end{array}
\]

\[
\begin{array}{ccc}
A \otimes A \otimes A & \xrightarrow{m \otimes \text{id}} & A \otimes A \\
\downarrow \text{id} \otimes m & & \downarrow m \\
A \otimes A & & A
\end{array}
\]

commute. Our goal in this section is to generalize the theory of associative algebras to the \( \infty \)-categorical setting.

The theory of associative algebras has a natural formulation in the language of operads. If \( \mathcal{C} \) is a symmetric monoidal category, then giving an associative algebra object of \( \mathcal{C} \) is equivalent to giving a map of colored operads \( \text{Ass} \to \mathcal{C} \), where \( \text{Ass} \) is the associative operad (Definition 4.1.1.1). In §4.1.1, we will obtain a theory of associative algebras in the \( \infty \)-categorical setting by using the construction of Example 2.1.1.21 to convert \( \text{Ass} \) into an \( \infty \)-operad \( \text{Ass}^\otimes \). We can then define an associative algebra object of a symmetric monoidal \( \infty \)-category \( \mathcal{C}^\otimes \) to be a map of \( \infty \)-operads \( \text{Ass}^\otimes \to \mathcal{C}^\otimes \).

The advantage of the approach taken in §4.1.1 is that it allows us to apply the general theory developed in Chapters 2 and 3 to the study of associative algebras. One disadvantage is that the simplicial set \( \text{Ass}^\otimes \) is somewhat complicated. In §4.1.2, we will remedy the situation by showing that, for many purposes, the \( \infty \)-operad \( \text{Ass}^\otimes \) can be replaced by the \( \infty \)-category \( N(\Delta)^{op} \): that is, associative algebras can be efficiently encoded as certain kinds of simplicial objects.

The theory of model categories provides a rich source of examples of monoidal \( \infty \)-categories. In §4.1.3, we will show that every monoidal model category \( A \) determines a monoidal \( \infty \)-category whose underlying \( \infty \)-category (if \( A \) is simplicial) can be identified with \( N(A^\circ) \). In this context, there is a close relationship between associative algebra objects of the \( \infty \)-category \( N(A^\circ) \) and (strict) associative algebra objects of the ordinary category \( A \), which we will discuss in §4.1.4.

4.1.1 The \( \infty \)-Operad \( \text{Ass}^\otimes \)

As a first step towards building an \( \infty \)-categorical theory of associative algebras, let us recast the classical theory of associative algebras in the language of operads.

**Definition 4.1.1.1.** We define a colored operad \( \text{Ass} \) (see Definition 2.1.1.1) as follows:

- The colored operad \( \text{Ass} \) has a single object, which we will denote by \(*\).

- For every finite set \( I \), the set \( \text{Mul}_{\text{Ass}}(\{*\}_{i \in I},*) \) can be identified with the set of linear orderings on \( I \).

- Suppose we are given a map of finite sets \( \alpha : I \to J \) together with operations \( \phi_j \in \text{Mul}_{\text{Ass}}(\{*\}_{\alpha(i)=j},*) \) and \( \psi \in \text{Mul}_{\text{Ass}}(\{*\}_{j \in J},*) \). We will identify each \( \phi_j \) with a linear ordering \( \preceq_j \) on \( \alpha^{-1}(j) \) and \( \psi \) with a linear ordering \( \preceq' \) on \( J \). The composition of \( \psi \) with \( \{\phi_j\} \) corresponds to the linear ordering \( \preceq \) on \( I \) which is defined as follows: \( i \preceq i' \) if either \( \alpha(i) \sim' \alpha(i') \) or \( \alpha(i) = j = \alpha(i') \) and \( i \preceq_j i' \).

We will refer to \( \text{Ass} \) as the *associative operad.*
Remark 4.1.1.2. Let $C$ be a symmetric monoidal category, and let $F : \text{Ass} \to C$ be a map of colored operads. Then $F(*)$ is an object $A \in C$. Given any linear ordering of a finite set $I$, the corresponding element of $\text{Mul}_{\text{Ass}}(\{\ast\}_i \in I, \ast)$ determines a map $A^{\otimes I} \to A$ in $C$. In particular, taking $I$ to be empty, we obtain a map $u : 1 \to A$ (where 1 denotes the unit object of $C$), and taking $I = \{1, 2\}$ (with its usual ordering) we obtain a map $m : A \otimes A \to A$. It is not difficult to see that these maps exhibit $A$ as an associative algebra in $C$. Conversely, if $A$ is any associative algebra in $C$, then we can associate to every finite linearly ordered set $I$ a map $A^{\otimes I} \to A$: this construction determines a map of colored operads $\text{Ass} \to C$. We can informally summarize the above discussion by saying that the theory of associative algebras is controlled by the colored operad $\text{Ass}$.

Definition 4.1.1.3. We let $\text{Ass}^\circ$ denote the category obtained by applying Construction 2.1.1.7 to the colored operad $\text{Ass}$, and $\text{Ass}^\circ$ denote the $\infty$-operad $N(\text{Ass}^\circ)$ (see Example 2.1.1.21). We will refer to $\text{Ass}^\circ$ as the associative $\infty$-operad.

Remark 4.1.1.4. Unwinding the definitions, we can describe $\text{Ass}^\circ$ as follows:

- The objects of $\text{Ass}^\circ$ are the objects of $\text{Fin}_*$.
- Given a pair of objects $\langle m \rangle, \langle n \rangle \in \text{Fin}_*$, a morphism from $\langle m \rangle$ to $\langle n \rangle$ in $\text{Ass}^\circ$ consists of a pair $(\alpha, \{\preceq_i\}_{1 \leq i \leq n})$, where $\alpha : \langle m \rangle \to \langle n \rangle$ is a map of pointed finite sets and $\preceq_i$ is a linear ordering on the inverse image $f^{-1}(i) \subseteq \langle m \rangle$ for $1 \leq i \leq n$.

- The composition of a pair of morphisms

$$
(f, \{\preceq_i\}_{1 \leq i \leq n}) : \langle m \rangle \to \langle n \rangle, \quad (g, \{\preceq'_j\}_{1 \leq j \leq p}) : \langle n \rangle \to \langle p \rangle
$$

is the pair $(g \circ f, \{\preceq''_j\}_{1 \leq j \leq p})$, where each $\preceq''_j$ is the lexicographical ordering characterized by the property that for $a, b \in \langle m \rangle$, such that $(g \circ f)(a) = (g \circ f)(b) = j$, we have $a \preceq''_j b$ if and only if $f(a) \preceq'_j f(b)$ and $a \preceq_i b$ if $f(a) = f(b) = i$.

Remark 4.1.1.5. Following the conventions of Chapter 2, we let $\text{Ass}$ denote the fiber $\text{Ass}^\circ \times_{N(\text{Fin}_*)}\{1\}$. As a simplicial set, $\text{Ass}$ is isomorphic to the 0-simplex $\Delta^0$. However, the notation $\text{Ass}$ emphasizes the role of this simplicial set as the underlying $\infty$-category for the $\infty$-operad $\text{Ass}^\circ$.

Definition 4.1.1.6. A planar $\infty$-operad is a fibration of $\infty$-operads $\mathcal{C}^\circ \to \text{Ass}^\circ$. If $\mathcal{C}^\circ \to \text{Ass}^\circ$ is a planar $\infty$-operad, we will often denote the $\infty$-category $\text{Alg}/_{\text{Ass}}(\mathcal{C})$ by $\text{Alg}(\mathcal{C})$; we will refer to $\text{Alg}(\mathcal{C})$ as the $\infty$-category of associative algebra objects of $\mathcal{C}$.

Remark 4.1.1.7. In the situation of Definition 4.1.1.6, we will often abuse terminology and simply refer to $\mathcal{C}^\circ$ as a planar $\infty$-operad. However, there is some danger of ambiguity: see Remark 4.1.1.8 below.

Remark 4.1.1.8. The colored operad $\text{Ass}$ is equipped with a canonical involution $\sigma$, which carries the unique object $\ast \in \text{Ass}$ to itself and carries an operation $\phi \in \text{Mul}_{\text{Ass}}(\{\ast\}_i \in I, \ast)$ corresponding to a linear order $\preceq$ on $I$ to the operation $\phi''$ which corresponds to the opposite ordering $\succeq$. This involution $\sigma$ induces an involution on the $\infty$-operad $\text{Ass}^\circ$.

If $\mathcal{C}^\circ \to \text{Ass}^\circ$ is a planar $\infty$-operad, then the composite map $\mathcal{C}^\circ \to \text{Ass}^\circ \xrightarrow{\sigma} \text{Ass}^\circ$ is another planar $\infty$-operad, which we will denote by $\mathcal{C}^\circ_{rev}$. We will refer to $\mathcal{C}^\circ_{rev}$ as the reverse of $\mathcal{C}^\circ$; note that the underlying $\infty$-category $\mathcal{C}^\circ_{rev}$ of $\mathcal{C}^\circ_{rev}$ is canonically isomorphic with $\mathcal{C}$. Composition with $\sigma$ induces an isomorphism $\text{Alg}(\mathcal{C}) \simeq \text{Alg}(\mathcal{C}^\circ_{rev})$. If $A \in \text{Alg}(\mathcal{C})$, we will denote to the image of $A$ under this isomorphism by $A^\circ_{rev}$, and refer to it as the opposite algebra of $A$.

If $\mathcal{D}^\circ$ is an $\infty$-operad and $\mathcal{C}^\circ = \mathcal{D}^\circ \times_{\text{Comm}^\circ \text{Ass}^\circ}$ is the underlying planar $\infty$-operad, then there is a canonical isomorphism $\mathcal{C}^\circ_{rev} \simeq \mathcal{C}^\circ$. It follows that passage to the opposite algebra can be regarded as a functor from the $\infty$-category $\text{Alg}/_{\text{Ass}}(\mathcal{C}) = \text{Alg}_{\text{Ass}}(\mathcal{D})$ to itself.
4.1. ASSOCIATIVE ALGEBRAS

**Notation 4.1.1.9.** Let $\mathcal{C}^\otimes$ be a generalized $\infty$-operad. We let $\text{Alg}(\mathcal{C})$ denote the $\infty$-category $\text{Alg}_{\text{Ass}}(\mathcal{C})$ of Ass-algebra objects of $\mathcal{C}$. If $\mathcal{C}^\otimes$ is an $\infty$-operad, then $\text{Alg}(\mathcal{C})$ can be identified with $\text{Alg}(\mathcal{D})$, where $\mathcal{D}^\otimes \simeq \mathcal{C}^\otimes \times_{\text{N}(\text{Fin},_n)} \text{Ass}^\otimes$ is the planar $\infty$-operad associated to $\mathcal{C}^\otimes$. This notation is potentially ambiguous: if $\mathcal{C}^\otimes$ is already equipped with a fibration of $\infty$-operads $q : \mathcal{C}^\otimes \to \text{Ass}^\otimes$, then the notation $\text{Alg}(\mathcal{C})$ has two different meanings, depending on whether we regard $\mathcal{C}^\otimes$ as a planar $\infty$-operad via $q$, or we ignore $q$ and simply regard $\mathcal{C}^\otimes$ as an $\infty$-operad. However, the ambiguity is slight: the $\infty$-category $\text{Alg}_{\text{Ass}}(\text{Ass})$ has only two objects, corresponding to the identity map $\text{Ass}^\otimes \to \text{Ass}^\otimes$ and the reversal involution of Remark 4.1.1.8. Consequently, if $\mathcal{C}^\otimes$ is a planar $\infty$-operad with an underlying $\infty$-operad which we denote by $\mathcal{C}_0^\otimes$, then $\text{Alg}(\mathcal{C}_0) \simeq \text{Alg}(\mathcal{C}) \coprod \text{Alg}(\mathcal{C}_{\text{rev}})$.

**Definition 4.1.1.10.** A monoidal $\infty$-category is a coCartesian fibration of $\infty$-operads $\mathcal{C}^\otimes \to \text{Ass}^\otimes$.

**Remark 4.1.1.11.** In the situation of Definition 4.1.1.10, we will often abuse terminology by referring to $\mathcal{C}^\otimes$ or the fiber $\mathcal{C} = \mathcal{C}^\otimes \times_{\text{Ass}^\otimes} \{1\}$ as a monoidal $\infty$-category.

**Remark 4.1.1.12.** Let $\mathcal{C}^\otimes \to \text{Ass}^\otimes$ be a monoidal $\infty$-category. For each $n \geq 0$, the fiber $\mathcal{C}^\otimes (n) \simeq \mathcal{C}^\otimes \times_{\text{Ass}^\otimes} \{n\}$ is canonically equivalent to $\mathcal{C}^\otimes \times_{\text{Ass}^\otimes} \{1\}$ up to homotopy; in particular, taking $n = 0$ we obtain an object $1 \in \mathcal{C}$, which we call the unit object, and taking $n = 2$ (and the ordering on $\{1,2\}$ to be the standard ordering) we obtain a functor $\mathcal{C} \times \mathcal{C} \to \mathcal{C}$. It is not difficult to see that the tensor product $\otimes$ is associative (with unit $1$) up to homotopy; in particular, the homotopy category $\text{hC}$ inherits a monoidal structure (in the usual sense).

**Remark 4.1.1.13.** Let $\mathcal{C}$ be a monoidal $\infty$-category. Evaluation on the object $\{1\} \in \text{Ass}^\otimes$ determines a forgetful functor $\theta : \text{Alg}(\mathcal{C}) \to \mathcal{C}$. We will often abuse notation by identifying an algebra object $A \in \text{Alg}(\mathcal{C})$ with its image $\theta(A) \in \mathcal{C}$. For each $n \geq 0$, every choice of ordering on the set $\{1,\ldots,n\}$ determines a map $\langle n \rangle \to \{1\}$ in $\text{Ass}^\otimes$, which induces a morphism $\theta(A)^{\otimes n} \to \theta(A)$ in $\mathcal{C}$. In particular, taking $n = 2$ and the standard ordering of the set $\{1,2\}$, we obtain a multiplication $m : \theta(A) \otimes \theta(A) \to \theta(A)$. It is not difficult to see that this multiplication map is associative and unital up to homotopy; in particular, it endows $\theta(A)$ with the structure of an associative algebra object of the monoidal category $\text{hC}$.

Recall that if $V$ is a vector space over a field $k$, then the free associative $k$-algebra generated by $V$ can be identified with the tensor algebra $\bigoplus_{n \geq 0} V^{\otimes n}$. Using the results of §3.1, we can obtain an analogous description of free associative algebras in a general monoidal $\infty$-category $\mathcal{C}$. Note that $\text{Ass}$ has a unique object $(1)$, and that the spaces $\mathcal{P}(n)$ appearing in Construction 3.1.3.9 are contractible. It follows that for each $C \in \mathcal{C}$, the objects $\text{Sym}^n_{\text{Ass}}(C)$ are automatically well-defined and given by the tensor power $C^{\otimes n}$. Applying Proposition 3.1.3.13 to this situation, we obtain:

**Proposition 4.1.1.14.** Let $\mathcal{C}$ be a monoidal $\infty$-category. Assume that $\mathcal{C}$ admits countable colimits and that the tensor product $\mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves countable colimits separately in each variable. Then the forgetful functor $\theta : \text{Alg}(\mathcal{C}) \to \mathcal{C}$ admits a left adjoint Fr. Moreover, given an object $A \in \text{Alg}(\mathcal{C})$ and an object $C \in \mathcal{C}$, a morphism $u : C \to \theta(A)$ is adjoint to an equivalence $\text{Fr}(C) \to A$ if and only if the maps $C^{\otimes n} \to \theta(A)^{\otimes n} \to \theta(A)$ determined by $u$ and the multiplication on $A$ induce an equivalence $\coprod_{n \geq 0} C^{\otimes n} \to \theta(A)$.

**Remark 4.1.1.15.** Proposition 4.1.1.14 admits a slight refinement: it is sufficient to assume that $\mathcal{C}$ admits countable coproducts (and that the tensor product functor $\mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves countable coproducts separately in each variable), rather than arbitrary countable colimits.

**Proposition 4.1.1.16.** The $\infty$-operad $\text{Ass}^\otimes$ is coherent (see Definition 3.3.1.9).

Consequently, to every associative algebra object $A$ of a monoidal $\infty$-category $\mathcal{C}$, we can associate an $\infty$-category of modules $\text{Mod}_{A}^{\otimes}(\mathcal{C})$. In §4.4, we will show that the objects of $\text{Mod}_{A}^{\otimes}(\mathcal{C})$ can be understood as $A$-$A$ bimodule objects of $\mathcal{C}$ (Theorem 4.4.1.28).
Definition 4.1.1.17. Let $\mathcal{C}$ be a monoidal $\infty$-category. We will say that $\mathcal{C}$ is left closed if, for each $C \in \mathcal{C}$, the functor $D \mapsto C \otimes D$ admits a right adjoint. Similarly, we will say that $\mathcal{C}$ is right closed if, for each $C \in \mathcal{C}$, the functor $D \mapsto D \otimes C$ admits a right adjoint. We will say that $\mathcal{C}$ is closed if it is both left closed and right closed.
4.1. ASSOCIATIVE ALGEBRAS

Remark 4.1.1.18. In view of Proposition T.5.2.2.12, the condition that a monoidal \( C \)-category \( \mathfrak{C} \) be closed can be checked at the level of the \((\mathfrak{C}\text{-enriched})\) homotopy category of \( \mathfrak{C} \), with its induced monoidal structure. More precisely, \( \mathfrak{C} \) is right closed if and only if, for every pair of objects \( C, D \in \mathfrak{C} \), there exists another object \( D^C \) and a map \( D^C \otimes C \to D \) with the following universal property: for every \( E \in \mathfrak{C} \), the induced map \( \text{Map}_\mathfrak{C}(E, D^C) \to \text{Map}_\mathfrak{C}(E \otimes C, D) \) is a homotopy equivalence. In this case, the construction \( D \mapsto D^C \) determines a right adjoint to the functor \( E \mapsto E \otimes C \).

Remark 4.1.1.19. Let \( \mathfrak{C} \) monoidal \( \infty \)-category. We say that an object \( C \in \mathfrak{C} \) is invertible if it is an invertible object of the homotopy category \( h\mathfrak{C} \): that is, if there exists an object \( D \in \mathfrak{C} \) and equivalences
\[
C \otimes D \simeq 1_{\mathfrak{C}} \simeq D \otimes C.
\]
Let \( \mathfrak{C}^0 \subseteq \mathfrak{C} \) denote the full subcategory spanned by the invertible objects. It is easy to see that the hypotheses of Proposition 2.2.1.1 are satisfied, so that \( \mathfrak{C}^0 \) inherits the structure of a monoidal \( \infty \)-category.

We conclude this section with the following observation:

Proposition 4.1.1.20. Let \( p : \mathfrak{C}^\circ \to \text{N}(\text{Fin}_n) \) be an \( \infty \)-operad. Then \( \mathfrak{C}^\circ \) is a symmetric monoidal \( \infty \)-category if and only if the induced map \( p' : \text{Ass}\circ \times_{\text{N}(\text{Fin}_n)} \mathfrak{C}^\circ \to \text{Ass}^\circ \) is a monoidal \( \infty \)-category.

Proof. The “only if” direction is obvious. For the converse, suppose that \( p' \) is a coCartesian fibration; we wish to prove that \( p \) is a coCartesian fibration. According to Corollary T.2.4.2.10, it will suffice to show that for every 2-simplex \( \sigma : \Delta^2 \to \text{N}(\text{Fin}_n) \), the pullback map \( \Delta^2 \times_{\text{N}(\text{Fin}_n)} \mathfrak{C}^\circ \to \Delta^2 \) is a coCartesian fibration. Since \( p' \) is a coCartesian fibration, it will suffice to show that \( \sigma \) factors through \( \text{Ass}^\circ \). This is clear: if \( \sigma \) corresponds to a pair of maps \( \langle l \rangle \to \langle m \rangle \xrightarrow{\beta} \langle n \rangle \), then a lifting of \( \sigma \) is determined by a choice of linear ordering on each of the fibers \( \alpha^{-1}\{i\} \) and each of the fibers \( \beta^{-1}\{j\} \).

4.1.2 Simplicial Models for Associative Algebras

Let \( \mathfrak{C} \) be an ordinary category which admits finite products. A monoid object of \( \mathfrak{C} \) is an object \( M \in \mathfrak{C} \), equipped with maps
\[
* \to M, \quad M \times M \to M
\]
which satisfy the usual associativity and unit conditions; here \( * \) denotes a final object of \( \mathfrak{C} \). Equivalently, we can define a monoid object of \( \mathfrak{C} \) to be a contravariant functor from \( \mathfrak{C} \) to the category of monoids, such that the underlying functor \( \mathfrak{C}^{\text{op}} \to \text{Set} \) is representable by an object \( M \in \mathfrak{C} \).

Example 4.1.2.1. If \( \mathfrak{C} \) is the category of sets, then a monoid object of \( \mathfrak{C} \) is simply a monoid \( M \). We can identify the monoid \( M \) with a category \( \mathcal{D}_M \), having only a single object \( E \) with \( \text{Hom}_{\mathcal{D}_M}(E, E) = M \). The nerve \( \text{N}(\mathcal{D}_M) \) is a simplicial set, which is typically denoted by \( BM \) and called the classifying space of \( M \). Concretely, the set of \( n \)-simplices of \( BM \) can be identified with an \( n \)-fold product of \( M \) with itself, and the face and degeneracy operations on \( BM \) encode the multiplication and unit operations on \( M \). The functor \( M \mapsto BM \) is a fully faithful embedding of the category of monoids into the category of simplicial sets. Moreover, a simplicial set \( X \) is isomorphic to the classifying space of a monoid if and only if, for each \( n \geq 0 \), the natural map \( X([n]) \to X(\{0,1\}) \times \ldots \times X(\{n-1,n\}) \) is a bijection. In this case, the underlying monoid is given by \( X([1]) \), with unit determined by the degeneracy map \( * \simeq X([0]) \to X([1]) \) and multiplication by the face map \( X([1]) \times X([1]) \simeq X([2]) \xrightarrow{\Delta} X([1]) \).

It follows from Example 4.1.2.1 that we can identify monoids in an arbitrary category \( \mathfrak{C} \) with certain simplicial objects of \( \mathfrak{C} \). This observation allows us to generalize the notion of a monoid to higher category theory.

Definition 4.1.2.2. Let \( \mathfrak{C} \) be an \( \infty \)-category. A monoid object of \( \mathfrak{C} \) is a simplicial object \( X : \text{N}(\Delta)^{\text{op}} \to \mathfrak{C} \) with the property that, for each \( n \geq 0 \), the collection of maps \( X([n]) \to X(\{i,i+1\}) \) exhibits \( X([n]) \) as a product \( X(\{0,1\}) \times \ldots \times X(\{n-1,n\}) \). We let \( \text{Mon}(\mathfrak{C}) \) denote the full subcategory of \( \text{Fun}(\text{N}(\Delta)^{\text{op}}, \mathfrak{C}) \) spanned by the monoid objects of \( \mathfrak{C} \).
Remark 4.1.2.3. Let $X$ be a monoid object of an $\infty$-category $\mathcal{C}$. We will sometimes abuse terminology and refer to $X([1]) \in \mathcal{C}$ as a monoid object of $\mathcal{C}$; note that $X([1])$ “controls” the simplicial object $X$ in the sense that $X([n]) \simeq X([1])^n$.

Example 4.1.2.4. Let $\mathcal{C}$ be an $\infty$-category. Every group object of $\mathcal{C}$ (see Definition T.7.2.2.1) is a monoid object of $\mathcal{C}$.

In §2.4.2, we introduced the notion of a $0$-monoid object of an $\infty$-category $\mathcal{C}$, where $\mathcal{O}^\otimes$ is an arbitrary $\infty$-operad (Definition 2.4.2.1). Our next goal is to show that when $\mathcal{O}^\otimes = \text{Ass}^\otimes$, then this recovers the theory of monoids given by Definition 4.1.2.2. To formulate this more precisely, we need to introduce a bit of notation.

Construction 4.1.2.5. Let $\Delta$ denote the category of combinatorial simplices. Given an object $[n] \in \Delta$, we define a cut in $[n]$ to be an equivalence relation on $[n]$ with at most two equivalence classes, each of which is a convex subset of $[n]$. The collection of all cuts in $[n]$ forms a set $\text{Cut}([n])$. There is a canonical bijection $\langle n \rangle \simeq \text{Cut}([n])$, which carries the base point $* \in \langle n \rangle$ to the trivial equivalence relation on $[n]$ (that is, the equivalence relation with only one equivalence class) and an element $i \in \langle n \rangle$ to the equivalence relation given by the partition $[n] = \{0, \ldots, i - 1\} \cup \{i, i + 1, \ldots, n\}$.

We can regard the construction $[n] \mapsto \text{Cut}([n])$ as a functor $\text{Cut} : \Delta^{op} \to \text{Ass}^\otimes$, where $\text{Ass}^\otimes$ is the functor defined in Definition 4.1.1.3. Namely, if we are given a map $\alpha : [m] \to [n]$ in $\Delta$, then there is an induced map $\alpha' : \text{Cut}([m]) \to \text{Cut}([n])$, which obviously preserves base points. Moreover, if $x \in \text{Cut}([m])$ is an equivalence relation with two equivalence classes, then every element of $\alpha'^{-1}(x)$ corresponds to a decomposition $[n] = S \cup T$ of $[n]$ into nonempty subsets $S, T \subseteq [n]$ such that $s < t$ for $s \in S, t \in T$. We therefore obtain a linear ordering on $\alpha'^{-1}(x)$, with $(S, T) \leq (S', T')$ if $S \subseteq S'$.

In more explicit terms, the functor $\text{Cut} : \Delta^{op} \to \text{Ass}^\otimes$ can be described as follows:

1. For each $n \geq 0$, we have $\text{Cut}([n]) = \langle n \rangle$.

2. Given a morphism $\alpha : [n] \to [m]$ in $\Delta$, the associated morphism $\text{Cut}(\alpha) : \langle m \rangle \to \langle n \rangle$ is given by the formula

$$\text{Cut}(\alpha)(i) = \begin{cases} j & \text{if } (\exists j)[\alpha(j - 1) < i \leq \alpha(j)] \\ * & \text{otherwise.} \end{cases}$$

where we endow each $\text{Cut}(\alpha)^{-1}\langle j \rangle$ with the linear ordering induced by its inclusion into $\langle n \rangle^\circ$.

The functor $\text{Cut}$ induces a map of simplicial sets $\text{N}(\Delta)^{op} \to \text{N}(\text{Ass}^\otimes) = \text{Ass}^\otimes$, which we will also denote by $\text{Cut}$.

Our comparison result can now be stated as follows:

Proposition 4.1.2.6. For every $\infty$-category $\mathcal{C}$ which admits finite products, composition with the functor $\text{Cut} : \text{N}(\Delta)^{op} \to \text{Ass}^\otimes$ of Construction 4.1.2.5 induces an equivalence of $\infty$-categories $\theta : \text{Mon}_{\text{Ass}}(\mathcal{C}) \to \text{Mon}(\mathcal{C})$.

We will deduce Proposition 4.1.2.6 from a much more general comparison result. To state it, we need a definition:

Definition 4.1.2.7. Let $p : \mathcal{O}^\otimes \to \text{N}(\text{Fin}_*)$ be an $\infty$-operad, let $f : \mathcal{E} \to \mathcal{O}^\otimes$ be a weak approximation to $\mathcal{O}^\otimes$ (see Definition 2.3.3.6). Choose a factorization of $f$ as a composition

$$\mathcal{E} \overset{f'}{\to} \mathcal{E}' \overset{f''}{\to} \mathcal{O}^\otimes$$

where $f'$ is a categorical equivalence and $f''$ is a categorical fibration. Let $\mathcal{C}$ be an arbitrary $\infty$-category. We will say that a functor $M : \mathcal{E} \to \mathcal{C}$ is a $\mathcal{E}$-monoid object of $\mathcal{C}$ if it satisfies the following condition:
4.1. ASSOCIATIVE ALGEBRAS

(*) Let \( E \in \mathcal{E} \) be an object with \((p \circ f)(E) = \langle n \rangle\), and choose maps \( \alpha_i : E \to E_i \) covering the maps \( \rho^i : \langle n \rangle \to \langle 1 \rangle \) such that such that \( f' \alpha_i \) is locally \((p \circ f'' \circ f')\)-coCartesian for \( 1 \leq i \leq n \). Then the maps \( M(\alpha_i) \) exhibit \( M(E) \) as a product \( \prod_{1 \leq i \leq n} M(E_i) \) in the \( \infty \)-category \( \mathcal{C} \).

We let \( \text{Mon}_\mathcal{E}(\mathcal{C}) \) denote the full subcategory of \( \text{Fun}(\mathcal{E}, \mathcal{C}) \) spanned by the \( \mathcal{C} \)-monoid objects.

**Remark 4.1.2.8.** In the situation of Definition 4.1.2.7, the condition that a functor \( M : \mathcal{E} \to \mathcal{C} \) be a \( \mathcal{C} \)-monoid depends only on the underlying map \( p' : \mathcal{E} \to N(\text{Fin}_*) \), and not on the particular presentation of \( \mathcal{E} \) as an approximation to an \( \infty \)-operad \( \mathcal{O} \otimes \) or on the factorization \( f \simeq f'' \circ f' \).

**Remark 4.1.2.9.** In the situation of Definition 4.1.2.7, assume that \( \mathcal{E} = {}^\text{op} \mathcal{O} \) is an \( \infty \)-operad. It follows from Remark 2.1.2.9 that \( \text{Mon}_\mathcal{E}(\mathcal{C}) \) and \( \text{Mon}_\mathcal{O}(\mathcal{C}) \) coincide (as subsets of \( \text{Fun}(\mathcal{E}, \mathcal{C}) \)).

We will deduce Proposition 4.1.2.6 from the following pair of assertions (see also Remark 4.1.2.12):

**Proposition 4.1.2.10.** The functor \( \text{Cut} : N(\Delta)^{\text{op}} \to \text{Ass} \) is an approximation to \( \text{Ass}^{\otimes} \).

**Proposition 4.1.2.11.** Let \( p : \mathcal{O} \to N(\text{Fin}_*) \) be an \( \infty \)-operad and let \( f : \mathcal{E} \to \mathcal{O}^{\otimes} \) be a weak approximation to \( \mathcal{O}^{\otimes} \). Assume that the induced map \( \mathcal{E} \times_{N(\text{Fin}_*)} \{1\} \to \mathcal{O} \) is an equivalence of \( \infty \)-categories. Then, for any \( \infty \)-category \( \mathcal{C} \) which admits finite products, composition with \( f \) induces an equivalence of \( \infty \)-categories \( \text{Mon}_\mathcal{E}(\mathcal{C}) \to \text{Mon}_\mathcal{O}(\mathcal{C}) \).

**Proof of Proposition 4.1.2.10.** We define a category \( \overline{\Delta}^{\text{op}} \) as follows: the objects of \( \overline{\Delta}^{\text{op}} \) are triples \((\{n\}, \{m\}, \alpha)\) where \( \{n\} \in \Delta^{\text{op}} \), \( \{m\} \in \text{Ass}^{\otimes} \), \( \alpha : \text{Cut}(\{n\}) \simeq \{m\} \) is an isomorphism in \( \text{Ass}^{\otimes} \) (the existence of which implies that \( m = n \)). The construction \( \{n\} \mapsto (\{n\}, \text{Cut}(\{n\}), \text{id}) \) determines an equivalence of categories \( \Delta^{\text{op}} \to \overline{\Delta}^{\text{op}} \), and the construction \((\{n\}, \{m\}, \alpha) \mapsto (\{m\})\) determines a categorical fibration \( \theta : N(\overline{\Delta})^{\text{op}} \to \text{Ass}^{\otimes} \). We will show that \( \theta \) is approximation to \( \text{Ass}^{\otimes} \).

Let \( \theta_0 \) denote the composite map \( N(\overline{\Delta})^{\text{op}} \to \text{Ass}^{\otimes} \to N(\text{Fin}_*) \). Note that the fiber \( \theta_0^{-1}(\{1\}) \) is isomorphic to \( \Delta^0 \); in particular, it contains a single vertex \((\{1\}, \{1\}, \text{id})\). For every object \((\{n\}, \{m\}, \alpha)\) in \( N(\overline{\Delta})^{\text{op}} \), the map

\[ \text{Hom}(\overline{\Delta}, \{1\}) \simeq \text{Hom}(\overline{\Delta}^{\text{op}}, \{\{n\}, \{m\}, \alpha\}) \to \text{Hom}_{\text{Fin}_*}(\{m\}, \{1\}) \]

is injective. It follows that every morphism \((\{n\}, \{m\}, \alpha) \to (\{1\}, \{1\}, \text{id})\) in \( N(\overline{\Delta})^{\text{op}} \) is locally \( \theta_0 \)-coCartesian. Moreover, for each \( 1 \leq i \leq m \), there is a unique morphism \((\{n\}, \{m\}, \alpha) \to (\{1\}, \{1\}, \text{id})\) covering the map \( \rho^i : \langle m \rangle \to \langle 1 \rangle \), which induces the map of linearly ordered sets \( [1] \simeq \{\alpha^{-1}(i) - 1, \alpha^{-1}(i)\} \subseteq \{n\} \). It follows that condition (1) of Definition 2.3.3.6 is satisfied.

To verify condition (2) of Definition 2.3.3.6, let us suppose we are given an object \((\{m\}, \{\alpha\}) \in N(\overline{\Delta})^{\text{op}} \) and an active morphism \( \beta : (\{m\}) \to (\{m\}) \) in \( \text{Ass}^{\otimes} \); we wish to show that \( \beta \) can be lifted to a \( \theta \)-Cartesian morphism \( \overline{\beta} \) in \( N(\overline{\Delta})^{\text{op}} \). Permuting the elements of \( \{m\} \) if necessary, we may suppose that \( \alpha = \text{id} \). For \( 1 \leq i \leq m \), let \( k_i \) be the cardinality of \( \beta^{-1}(i) \). Permuting the elements of \( \{m\} \) if necessary, we may assume that \( \beta^{-1}(i) = \{k_1 + \cdots + k_{i-1} + 1, k_1 + \cdots + k_{i-1} + 2, \ldots, k_1 + \cdots + k_{i-1} + k_i\} \) equipped with its usual ordering. In this case, the map of linearly ordered sets \( [m] \to [m'] \) given by \( i \mapsto k_1 + \cdots + k_i \) determines a map \( \overline{\beta} : (\{m'\}, \{\alpha\}, \text{id}) \to (\{m\}, \{\alpha\}, \text{id}) \) lifting the map \( \beta \). A simple calculation shows that \( \overline{\beta} \) is \( \theta \)-Cartesian. \( \square \)

**Remark 4.1.2.12.** Let \( \text{Cut} : N(\Delta)^{\text{op}} \to \text{Ass}^{\otimes} \) be the approximation of Proposition 4.1.2.10. The proof given above shows that the morphisms \( \alpha_i : E \to E_i \) appearing in condition (\*) of Definition 4.1.2.7 are precisely those maps of \( N(\Delta)^{\otimes} \) which correspond to inclusions \( [1] \simeq \{i, i + 1\} \hookrightarrow \{n\} \in \Delta \). It follows that for any \( \infty \)-category \( \mathcal{C} \), the \( \infty \)-categories \( \text{Mon}(\mathcal{C}) \) and \( \text{Mon}(N(\Delta)^{\otimes}) \) coincide (as full subcategories of \( \text{Fun}(N(\Delta)^{\otimes}, \mathcal{C}) \)). Consequently, Proposition 4.1.2.6 is an immediate consequence of Propositions 4.1.2.10 and 4.1.2.11.

**Proof of Proposition 4.1.2.11.** We employ the same strategy as in the proof of Theorem 2.3.3.23, but the details are slightly easier. We may assume without of generality that the weak approximation \( \mathcal{E} \to \mathcal{O}^{\otimes} \) is a categorical fibration. Choose a Cartesian fibration \( u : M \to \Delta^1 \) associated to the functor \( f \), so that we have isomorphisms \( \mathcal{O}^{\otimes} \simeq M \times \Delta^1 \{0\}, \mathcal{C} \simeq M \times \Delta^1 \{1\} \), and choose a retraction \( r \) from \( M \) onto \( \mathcal{O}^{\otimes} \) such that \( r|\mathcal{C} = f \). Let \( \mathcal{X} \) denote the full subcategory of \( \text{Fun}(M, \mathcal{C}) \) spanned by those functors \( F : M \to \mathcal{C} \) satisfying the following conditions:
(i) The restriction $F|\mathcal{O}^\otimes$ belongs to $\mathrm{Mon}_\mathcal{O}(\mathcal{C})$.

(ii) For every $u$-Cartesian morphism $\alpha$ in $\mathcal{M}$, the image $F(\alpha)$ is an equivalence in $\mathcal{C}$.

Condition (ii) is equivalent to the requirement that $F$ be a left Kan extension of $F|\mathcal{O}^\otimes$. Using Proposition T.4.3.2.15, we conclude that the restriction functor $\mathcal{X} \to \mathrm{Mon}_\mathcal{O}(\mathcal{C})$ is a trivial Kan fibration. Composition with $r$ determines a section $s$ of this trivial Kan fibration. Let $\psi: \mathcal{X} \to \mathrm{Fun}(\mathcal{E}, \mathcal{C})$ be the other restriction functor. Then the forgetful functor $\mathrm{Mon}_\mathcal{O}(\mathcal{C}) \to \mathrm{Fun}(\mathcal{E}, \mathcal{C})$ is given by the composition $\psi \circ s$. It will therefore suffice to show that $\psi$ determines an equivalence from $\mathcal{X}$ onto $\mathrm{Mon}_\mathcal{E}(\mathcal{C})$. In view of Proposition T.4.3.2.15, it will suffice to verify the following:

(a) Let $F_0 \in \mathrm{Mon}_\mathcal{E}(\mathcal{C})$. Then there exists a functor $F \in \mathrm{Fun}(\mathcal{M}, \mathcal{C})$ which is a right Kan extension of $F_0$.

(b) A functor $F \in \mathrm{Fun}(\mathcal{M}, \mathcal{C})$ belongs to $\mathcal{X}$ if and only if $F$ is a right Kan extension of $F_0 = F|\mathcal{E}$, and $F_0 \in \mathrm{Mon}_\mathcal{E}(\mathcal{C})$.

We begin by proving (a). Fix an object $X \in \mathcal{O}^\otimes$, let $\mathcal{E}_{X/}$ denote the fiber product $\mathcal{M}_{X/} \times_{\mathcal{M}} \mathcal{E}$, and let $F_X = F_0|\mathcal{E}_{X/}$. According to Lemma T.4.3.2.13, it will suffice to show that the functor $F_X$ can be extended to a limit diagram $\mathcal{E}_{X/}^q \to \mathcal{C}$. Let $\mathcal{E}_{X/}'$ denote the full subcategory of $\mathcal{E}_{X/}$ spanned by those morphisms $X \to C$ in $\mathcal{M}$ which correspond to inert morphisms $X \to f(C)$ in $\mathcal{O}^\otimes$. Since $f$ is a weak approximation to $\mathcal{O}^\otimes$, Theorem T.4.1.3.1 implies that the inclusion $\mathcal{E}_{X/}' \hookrightarrow \mathcal{E}_{X/}$ is right cofinal. It will therefore suffice to show that the restriction $F_X' = F_X|\mathcal{E}_{X/}'$ can be extended to a limit diagram $\mathcal{E}_{X/}' \to \mathcal{C}$.

Let $\langle n \rangle = p(X)$, and let $\mathcal{E}_{X/}''$ denote the full subcategory of $\mathcal{E}_{X/}'$ corresponding to inert morphisms $X \to f(C)$ for which $(p \circ f)(C) = \langle 1 \rangle$. We claim that $F_X'$ is a right Kan extension of $F_X'' = F|\mathcal{E}_{X/}''$. To prove this, let us choose an arbitrary object of $\mathcal{E}_{X/}'$, given by a map $\alpha: X \to C$ in $\mathcal{M}$. The fiber product $\mathcal{E}_{X/}'' \times_{\mathcal{E}_{X/}'} (\mathcal{E}_{X/}'|\alpha)$ can be identified with the full subcategory of $\mathcal{M}_\alpha$ spanned by those diagrams $X \alpha \to C C$ such that $(p \circ f)(\beta)$ has the form $\rho^i: \langle n \rangle \to \langle 1 \rangle$, for some $1 \leq i \leq n$. In particular, this $\infty$-category is a disjoint union of full subcategories $\{\mathcal{D}(i)\}_{1 \leq i \leq n}$, where each $\mathcal{D}(i)$ is equivalent to the full subcategory of $\mathcal{E}_C$ spanned by morphisms $C \to C'$ covering the map $\rho^i$. Our assumption that $f$ is a weak approximation to $\mathcal{O}^\otimes$ guarantees that each of these $\infty$-categories has a final object, given by a locally $(p \circ f)$-coCartesian morphism $C \to C_i$ in $\mathcal{C}$. It will therefore suffice to show that $F_0(C_i)$ is a product of the objects $\{F_0(C_i)\}_{1 \leq i \leq n}$. Since $\mathcal{C}$ is an $\infty$-operad, we are reduced to proving that each of the maps $F_0(C_i) \to F_0(C_i)$ is inert, which follows from our assumption that $F_0 \in \mathrm{Mon}_\mathcal{E}(\mathcal{C})$.

Using Lemma T.4.3.2.7, we are reduced to proving that the diagram $F_X''$ can be extended to a limit diagram $\mathcal{E}_{X/}'' \to \mathcal{C}$. For $1 \leq i \leq n$, let $\mathcal{E}(i)^{\mathcal{M}_{X/}}_{X/}$ denote the full subcategory of $\mathcal{E}_{X/}$ spanned by those objects for which the underlying morphism $X \to C$ covers $\rho^i: p(X) \simeq \langle n \rangle \to \langle 1 \rangle$. Then $\mathcal{E}_{X/}''$ is the disjoint union of the full subcategories $\{\mathcal{E}(i)^{\mathcal{M}_{X/}}_{X/}\}$. Let $\mathcal{O}(i)$ denote the full subcategory of $\mathcal{O}_{X/}^{\otimes} \times_{\mathcal{N}(\mathcal{O}_{\mathcal{M}_{i/}})} \{\rho^i\}$, so that we have a left fibration of simplicial sets $\mathcal{O}(i) \to \emptyset$ and a categorical equivalence $\mathcal{E}(i)^{\mathcal{M}_{X/}}_{X/} \simeq \mathcal{O}(i) \times_{\emptyset} \mathcal{E}$. Choose inert morphisms $X \to X_i$ in $\mathcal{O}^\otimes$ for $1 \leq i \leq n$, so that each $X_i$ determines an initial object of $\mathcal{O}(i)$. If $f$ induces a categorical equivalence $\mathcal{E} \times_{\mathcal{N}(\mathcal{O}_{\mathcal{M}_{i/}})} \{\langle 1 \rangle\} \to \emptyset$, then we can write $X_i \simeq f(C_i)$ for some $C_i \in \mathcal{C}$, and that the induced map $X \to C_i$ can be identified with a final object of $\mathcal{O}(i)^{\mathcal{M}_{X/}}_{X/}$. Consequently, we are reduced to proving the existence of a product for the set of objects $\{F_0(C_i)\}_{1 \leq i \leq n}$, which follows from our assumption that $\mathcal{C}$ admits finite products. This completes the proof of (a). Moreover, it yields the following version of (b):

(b') Let $F \in \mathrm{Fun}(\mathcal{M}, \mathcal{C})$ be such that $F_0 = F|\mathcal{E} \in \mathrm{Mon}_\mathcal{E}(\mathcal{C})$. Then $F$ is a right Kan extension of $F_0$ if and only if, for every object $X \in \mathcal{O}^\otimes_{\langle n \rangle}$, if we choose $C_i \in \mathcal{C}$ and maps $\alpha_i: X \to C_i$ in $\mathcal{M}$ corresponding to inert morphisms $X \to f(C_i)$ in $\mathcal{O}^\otimes$ covering $\rho^i: \langle n \rangle \to \langle 1 \rangle$ for $1 \leq i \leq n$, then the induced map $F(X) \to \prod_{1 \leq i \leq n} F_0(C_i)$ is an equivalence in $\mathcal{C}$. 
4.1. ASSOCIATIVE ALGEBRAS

We now prove (b). Assume first that $F \in \mathcal{X}$. Then $F_0 = F|\mathcal{E}$ is equivalent to the functor $(F|\mathcal{O}^\otimes) \circ f$. It follows immediately that $F_0 \in \text{Mon}_\mathcal{E}(\mathcal{C})$. Criterion (b') immediately implies that $F$ is a right Kan extension of $F_0$. This proves the “only if” direction.

For the converse, assume that $F_0 \in \text{Mon}_\mathcal{E}(\mathcal{C})$ and that $F$ is a right Kan extension of $F_0$. We wish to prove that $F \in \mathcal{X}$. We first verify that $F$ satisfies (ii). Pick an object $C \in \mathcal{E}$ and choose locally $(p \circ f)$-coCartesian morphisms $\alpha_i : C \to C_i$ for $1 \leq i \leq n$. Let $X = f(C)$; we wish to show that the induced map $F(X) \to F(C)$ is an equivalence in $\mathcal{C}$. Since $F_0 \in \text{Mon}_\mathcal{E}(\mathcal{C})$, we can identify $F(C)$ with the product $\prod_{1 \leq i \leq n} F(C_i)$, so that the desired assertion follows immediately from (b').

To complete the proof, we must show that $F|\mathcal{O}^\otimes$ belongs to $\text{Mon}_\mathcal{O}(\mathcal{C})$. Let $X \in \mathcal{O}^\otimes_{(n)}$ and choose inert morphisms $\alpha_i : X \to X_i$ covering $\rho^i : \{n\} \to \{1\}$ for $1 \leq i \leq n$; we wish to show that the induced map $F(X) \to \prod_{1 \leq i \leq n} F(C_i)$ is an equivalence. We may assume without loss of generality that $X_i = f(C_i)$ for some objects $\{C_i \in \mathcal{E}\}_{1 \leq i \leq n}$. Condition (ii) implies that $F$ induces an equivalence $F(X_i) \to F(C_i)$ for $1 \leq i \leq n$. We are therefore reduced to showing that the map $F(X) \to \prod_{1 \leq i \leq n} F(C_i)$ is an equivalence in $\mathcal{C}$, which follows from criterion (b').

Combining Proposition 4.1.2.6 with Proposition 2.4.2.5, we conclude that if $\mathcal{C}$ is an $\infty$-category equipped with a Cartesian symmetric monoidal structure, then there is a canonical equivalence $\text{Alg}_{\text{Ass}}(\mathcal{C}) \to \text{Mon}(\mathcal{C})$. Using Theorem 2.3.3.23, we can obtain an analogous statement for an arbitrary monoidal $\infty$-category $\mathcal{C}$. To formulate it, we need a bit of notation.

**Definition 4.1.2.13.** We will say that a morphism $\alpha : [m] \to [n]$ in $\Delta$ is inert if the induced map $\text{Cut}([m]) \to \text{Cut}([n])$ is an inert morphism in $\text{Ass}^\otimes$. More directly, $\alpha : [m] \to [n]$ is inert if it induces an isomorphism from $[m]$ onto a convex subset $\{i, i + 1, \ldots, j - 1, j\} \subseteq [n]$.

**Definition 4.1.2.14.** Let $\mathcal{C}^\otimes \to \text{Ass}^\otimes$ be a planar $\infty$-operad. We let $\Delta^\text{Alg}(\mathcal{C})$ denote the full subcategory of $\text{Fun}_{\text{Ass}^\otimes}(\text{N}(\Delta)^{op}, \mathcal{C}^\otimes)$ spanned by those functors $F : \text{N}(\Delta)^{op} \to \mathcal{C}^\otimes$ which carry inert morphisms of $\text{N}(\Delta)^{op}$ to inert morphisms of $\mathcal{C}^\otimes$.

The following result is an immediate consequence of Theorem 2.3.3.23 and Proposition 4.1.2.10:

**Proposition 4.1.2.15.** Let $\mathcal{C}^\otimes$ be a planar $\infty$-operad. Then composition with the functor $\text{Cut} : \text{N}(\Delta)^{op} \to \text{Ass}^\otimes$ of Construction 4.1.2.5 induces an equivalence of $\infty$-categories $\text{Alg}(\mathcal{C}) \to \Delta^\text{Alg}(\mathcal{C})$.

**Remark 4.1.2.16.** We will generally abuse terminology by referring to objects of $\Delta^\text{Alg}(\mathcal{C})$ as associative algebra objects of $\mathcal{C}$. This abuse is justified by Proposition 4.1.2.15.

4.1.3 Monoidal Model Categories

Let $\mathbf{A}$ be a monoidal category which is equipped with a model structure. Recall that $\mathbf{A}$ is said to be a monoidal model category if the unit object $1 \in \mathbf{A}$ is cofibrant, the monoidal structure on $\mathbf{A}$ is closed, and the tensor product functor $\otimes : \mathbf{A} \times \mathbf{A} \to \mathbf{A}$ is a left Quillen bifunctor. (For a more leisurely introduction to the theory of monoidal model categories, we refer the reader to [72] or to the appendix of [97]). Our goal in this section is to extract from $\mathbf{A}$ a monoidal $\infty$-category $\mathcal{C}^\otimes$. In the case where $\mathbf{A}$ is simplicial, the $\infty$-category $\mathcal{C}$ can be described as the homotopy coherent nerve $\text{N}(\mathbf{A}^\circ)$, where $\mathbf{A}^\circ$ is the collection of fibrant-cofibrant objects of $\mathbf{A}$. However, the assumption that $\mathbf{A}$ is simplicial is inconvenient for many applications (for example, in the case where $\mathbf{A}$ is the category of chain complexes of vector spaces over some field $k$). In the general case, we can describe $\mathcal{C}$ instead as the the $\infty$-category obtained from $\mathbf{A}$ by formally inverting the collection of weak equivalences. We begin with a few general remarks about this procedure.

**Construction 4.1.3.1.** Let $\mathcal{C}$ be an $\infty$-category. We define a system on $\mathcal{C}$ to be a collection of morphisms $W \subseteq \text{Hom}_{\text{set}}(\Delta^1, \mathcal{C})$ which is stable under homotopy, composition, and contains all equivalences. In other words, a system on $\mathcal{C}$ is a subcategory of the homotopy category $\text{hC}$, which contains all objects and isomorphisms in $\text{hC}$. The collection of systems on $\mathcal{C}$ forms a partially ordered set $\text{Sys}(\mathcal{C})$. We regard the construction $\mathcal{C} \mapsto \text{N}(\text{Sys}(\mathcal{C}))$ as a functor $\text{Cat}^{op}_\infty \to \text{Cat}_\infty$, which classifies a Cartesian fibration $q :$
\( \mathcal{W}\text{Cat}_\infty \to \mathcal{C}\text{at}_\infty \). Unwinding the definitions, we can identify the objects of \( \mathcal{W}\text{Cat}_\infty \) with pairs \((\mathcal{C}, W)\), where \( \mathcal{C} \) is an \( \infty \)-category and \( W \) is a system on \( \mathcal{C} \). Unwinding the definitions, we see that for objects \((\mathcal{C}, W), (\mathcal{C}', W') \in \mathcal{W}\text{Cat}_\infty \), the mapping space

\[
\text{Map}_{\mathcal{W}\text{Cat}_\infty}((\mathcal{C}, W), (\mathcal{C}', W'))
\]

can be described as the summand of \( \text{Map}_{\mathcal{C}\text{at}_\infty}(\mathcal{C}, \mathcal{C}') \) spanned by those functors \( f : \mathcal{C} \to \mathcal{C}' \) such that \( f(W) \subseteq W' \).

The Cartesian fibration \( q \) admits a section \( G \), given by the formula \( G(\mathcal{C}) = (\mathcal{C}, W) \) where \( W \) is the collection of all equivalences in \( \mathcal{C} \).

**Proposition 4.1.3.2.** Let \( G : \mathcal{C}\text{at}_\infty \to \mathcal{W}\text{Cat}_\infty \) be the functor described in Construction 4.1.3.1. Then \( G \) admits a left adjoint. Moreover, this left adjoint commutes with finite products.

**Notation 4.1.3.3.** In the situation of Proposition 4.1.3.2, we will denote the left adjoint to \( G \) by \((\mathcal{C}, W) \to \mathcal{C}[W^{-1}]\).

**Proof.** Let \((\mathcal{C}, W)\) be an object of \( \mathcal{W}\text{Cat}_\infty \), and regard \((\mathcal{C}, W)\) as an object of the category \( \text{Set}^\Delta_+ \) of marked simplicial sets. Choose a marked equivalence \( i : (\mathcal{C}, W) \to (\mathcal{C}', W') \), where \((\mathcal{C}', W')\) is a fibrant object of \( \text{Set}^\Delta_+ \). Then \((\mathcal{C}', W') = G(\mathcal{C}')\). It follows immediately from the definitions that for any \( \infty \)-category \( \mathcal{D} \), composition with \( i \) induces a homotopy equivalence \( \text{Map}_{\mathcal{C}\text{at}_\infty}(\mathcal{C}', \mathcal{D}) \to \text{Map}_{\mathcal{W}\text{Cat}_\infty}((\mathcal{C}, W), G(\mathcal{D})) \). The assertion regarding products follows from Proposition T.3.1.4.2.

In what follows, let us regard \( \mathcal{W}\text{Cat}_\infty \) and \( \mathcal{C}\text{at}_\infty \) as endowed with the Cartesian symmetric monoidal structures. For any \( \infty \)-operad \( \mathcal{O} \), composition with the functor \( G \) induces a fully faithful embedding \( \text{Alg}_\mathcal{O}(\mathcal{C}\text{at}_\infty) \simeq \text{Mon}_\mathcal{O}(\mathcal{C}\text{at}_\infty) \to \text{Mon}_\mathcal{O}(\mathcal{W}\text{Cat}_\infty) \simeq \text{Alg}_\mathcal{O}(\mathcal{W}\text{Cat}_\infty) \). It follows from Propositions 4.1.3.2 and 2.2.1.9 that this fully faithful embedding admits a left adjoint. Combining this observation with Example 2.4.2.4, we obtain the following result:

**Proposition 4.1.3.4.** Let \( \mathcal{C}^\otimes \) be a (symmetric) monoidal \( \infty \)-category, and let \( W \) be a collection of morphisms in \( \mathcal{C} \). Assume that for every object \( C \in \mathcal{C} \) and every morphism \( f : D \to D' \) in \( W \), the induced maps

\[
C \otimes D \to C \otimes D' \quad D \otimes C \to D' \otimes C
\]

also belong to \( W \), so that \((\mathcal{C}, W)\) can be regarded as a (commutative) monoid object of \( \mathcal{W}\text{Cat}_\infty \).

1. There exists a (symmetric) monoidal \( \infty \)-category \( \mathcal{D}^\otimes \), with the following universal property: for every (symmetric) monoidal \( \infty \)-category \( \mathcal{D}^\otimes \), composition with \( F \) induces a fully faithful embedding from the \( \infty \)-category of (symmetric) monoidal functors \( \mathcal{C}^\otimes \to \mathcal{D}^\otimes \) to the \( \infty \)-category of (symmetric) monoidal functors \( \mathcal{C}^\otimes \to \mathcal{D}^\otimes \). Moreover, the essential image of this embedding consists of those symmetric monoidal functors \( \mathcal{C}^\otimes \to \mathcal{D}^\otimes \) which carry each morphism in \( W \) to an equivalence in \( \mathcal{D} \).

2. The underlying \( \infty \)-category of \( \mathcal{C}^\otimes \) can be identified with the \( \infty \)-category \( \mathcal{C}[W^{-1}] \) of Notation 4.1.3.3.

**Remark 4.1.3.5.** In the situation of Proposition 4.1.3.4, the (symmetric) monoidal functor \( F : \mathcal{C}^\otimes \to \mathcal{C}'^\otimes \) is characterized up to equivalence by property (2). Indeed, suppose we are given another symmetric monoidal functor \( G : \mathcal{C}^\otimes \to \mathcal{C}''^\otimes \) satisfying (2). Using (1), we conclude that \( G \) is equivalent to a composition

\[
\mathcal{C}^\otimes \xrightarrow{F} \mathcal{C}'^\otimes \xrightarrow{\iota} \mathcal{C}''^\otimes.
\]

Then \( G' \) induces an equivalence \( \mathcal{C}' \simeq \mathcal{C}'' \) (both are equivalent to \( \mathcal{C}[W^{-1}] \)), so that \( G' \) is an equivalence of (symmetric) monoidal \( \infty \)-categories by Remark 2.1.3.8.
4.1. ASSOCIATIVE ALGEBRAS

Example 4.1.3.6. Let $A$ be a (symmetric) monoidal model category. Then the full subcategory $A^c \subseteq A$ inherits a (symmetric) monoidal structure. Moreover, the collection $W$ of weak equivalences in $A^c$ is stable under (left and right) tensor product by objects of $A^c$. It follows that the underlying $\infty$-category $N(A^c)[W^{-1}]$ of $A$ inherits a (symmetric) monoidal structure. We will refer to the (symmetric) monoidal $\infty$-category $N(A^c)[W^{-1}]$ as the underlying (symmetric) monoidal $\infty$-category of $A$.

Our final goal in this section is to give an explicit description of the monoidal structure on the underlying $\infty$-category of a monoidal model category $A$, in the special case where $A$ is equipped with a simplicial structure.

Definition 4.1.3.7. Let $\mathcal{C}$ be simplicial category. We will say that a monoidal structure on $\mathcal{C}$ is weakly compatible with the simplicial structure on $\mathcal{C}$ provided that the operation $\otimes: \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ is endowed with the structure of a simplicial functor, which is compatible with associativity and unit constraints of $\mathcal{C}$. We will say that a symmetric monoidal structure on $\mathcal{C}$ is weakly compatible with the simplicial structure on $\mathcal{C}$ if the underlying monoidal category is weakly compatible with the simplicial structure on $\mathcal{C}$ and, in addition, the symmetry constraint $\eta_{X,Y} : X \otimes Y \to Y \otimes X$ is a natural transformation of simplicial functors.

Suppose furthermore that the monoidal structure on $\mathcal{C}$ is closed: that is, for every pair objects $X, Y \in \mathcal{C}$, there exist an exponential objects $X^Y, Y^X \in \mathcal{C}$ and evaluation map

$$e : X^Y \otimes Y \to X \quad e' : Y \otimes Y^X \to X$$

which induce bijections

$$\text{Hom}_\mathcal{C}(Z, X^Y) \to \text{Hom}_\mathcal{C}(Z \otimes Y \to X) \quad \text{Hom}_\mathcal{C}(Z, Y^X) \to \text{Hom}_\mathcal{C}(Y \otimes Z, X)$$

for every object $Z \in \mathcal{C}$. We will say that a (symmetric) monoidal structure on $\mathcal{C}$ is compatible with a simplicial structure on $\mathcal{C}$ if it is weakly compatible, and the maps $e$ and $e'$ induce isomorphisms of simplicial sets

$$\text{Map}_\mathcal{C}(Z, X^Y) \to \text{Map}_\mathcal{C}(Z \otimes Y, X) \quad \text{Map}_\mathcal{C}(Z, Y^X) \to \text{Map}_\mathcal{C}(Y \otimes Z, X)$$

for every $Z \in \mathcal{C}$.

Definition 4.1.3.8. A simplicial (symmetric) monoidal model category is a (symmetric) monoidal model category which is also equipped with the structure of a simplicial model category, where the simplicial structure and the (symmetric) monoidal structure are compatible in the sense of Definition 4.1.3.7.

Remark 4.1.3.9. In the symmetric case, one can reformulate Definition 4.1.3.8 as follows. Let $A$ be a symmetric monoidal model category. Then a compatible simplicial structure on $A$ can be identified with symmetric monoidal left Quillen functor $\psi : \text{Set}_\Delta \to A$. Given such a functor, $A$ inherits the structure of a simplicial category, where the mapping spaces are characterized by the existence of a natural bijection

$$\text{Hom}_{\text{Set}_\Delta}(K, \text{Map}_A(A, B)) \simeq \text{Hom}_A(\psi(K) \otimes A, B).$$

Proposition 4.1.3.10. Let $A$ be a simplicial symmetric monoidal model category, and let $A^o$ denote the full subcategory spanned by the fibrant-cofibrant objects. We regard $A^o$ as a simplicial colored operad via the formula

$$\text{Mul}_{A^o}({X_i}, Y) = \text{Map}_A(\bigotimes_i X_i, Y).$$

Then the operadic nerve $N^\otimes(A^o)$ is a symmetric monoidal $\infty$-category.

Remark 4.1.3.11. In the situation of Proposition 4.1.3.10, the simplicial colored operad $A^o$ is fibrant: that is, each of the mapping spaces $\text{Mul}_{A^o}({X_i}, Y) = \text{Map}_A(\bigotimes_i X_i, Y)$ is a Kan complex. This follows from the fact that $Y$ is fibrant and $\bigotimes_i X_i$ is cofibrant (being a tensor product of cofibrant objects of $A$). Invoking Proposition 2.1.1.27, we deduce that $p : N^\otimes(A^o) \to N(\text{Fin}_*)$ is an $\infty$-operad.
Remark 4.1.3.13. Let \( \mathcal{M} \) be a simplicial symmetric monoidal model category. We define a simplicial category \( \mathcal{M}^\otimes \) as follows:

1. An object of \( \mathcal{M}^\otimes \) is a sequence \((i, A_1, \ldots, A_n)\), where \((A_1, \ldots, A_n)\) is a finite sequence of cofibrant objects of \( \mathcal{A} \) and \( i \in \{0, 1\} \). We further assume that if \( i = 1 \), then each \( A_j \) is a fibrant object of \( \mathcal{A} \).

2. Suppose we are given objects \((i_A, A_1, \ldots, A_n)\) and \((i_A', A_1', \ldots, A_n')\) in \( \mathcal{M}^\otimes \). Then
   \[
   \text{Map}_\mathcal{M}((i_A, A_1, \ldots, A_n), (i_A', A_1', \ldots, A_n')) = \begin{cases} 
   \prod_{\alpha} \prod_{1 \leq j' \leq n'} \text{Map}_\mathcal{A}(\bigotimes_{\alpha(j') = j'} A_j, A_{j'}) & \text{if } i_A' = 1 \\
   \prod_{\alpha} \prod_{1 \leq j' \leq n'} \text{Hom}_\mathcal{A}(\bigotimes_{\alpha(j') = j'} A_j, A_{j'}) & \text{if } i_A = i_A' = 0 \\
   \emptyset & \text{if } i_A' < i_A.
   \end{cases}
   \]

Here the disjoint unions are taken over all morphisms \( \alpha : \langle n \rangle \to \langle n' \rangle \) in the category \( \text{N}(\text{Fin}_*) \).

Remark 4.1.3.14. Let \( \mathcal{A} \) be a simplicial symmetric monoidal model category, and let \( \mathcal{M}^\otimes \) be as in Construction 4.1.3.12. The construction \((i_A, A_1, \ldots, A_n) \mapsto (i, \langle n \rangle)\) determines a forgetful functor \( N(\mathcal{M}) \to \Delta^1 \times \text{N}(\text{Fin}_*) \). We have canonical isomorphisms
   \[
   N(\mathcal{M}) \times_{\Delta^1} \{0\} \simeq N^\otimes(\mathcal{A}^c) \quad N(\mathcal{M}) \times_{\Delta^1} \{1\} \simeq N^\otimes(\mathcal{A}^o).
   \]

Proposition 4.1.3.15. Let \( \mathcal{A} \) be a simplicial symmetric monoidal model category, and let \( \mathcal{M}^\otimes \) be defined as in Construction 4.1.3.12. Then the induced map \( p : N(\mathcal{M}) \to \Delta^1 \times \text{N}(\text{Fin}_*) \) is a coCartesian fibration.

Proposition 4.1.3.15 immediately implies Proposition 4.1.3.10 (by passing to the fiber over \( \{1\} \in \Delta^1 \) and invoking Remark 4.1.3.14). Moreover, it shows that \( N(\mathcal{M}) \) is the correspondence associated to a symmetric monoidal functor \( N^\otimes(\mathcal{A}^c) \to N^\otimes(\mathcal{A}^o) \). Combining this observation with Remark 4.1.3.5 and Theorem 1.3.4.20, we obtain the following:

Corollary 4.1.3.16. Let \( \mathcal{A} \) be a simplicial symmetric monoidal model category. Then the symmetric monoidal functor \( N^\otimes(\mathcal{A}^c) \to N^\otimes(\mathcal{A}^o) \) constructed above exhibits \( N^\otimes(\mathcal{A}^o) \) as the underlying symmetric monoidal \( \infty \)-category of \( \mathcal{A} \), in the sense of Example 4.1.3.6.

Proof of Proposition 4.1.3.15. Let \((i, C_1, \ldots, C_n)\) be an object of \( \mathcal{M}^\otimes \), and let \( \alpha : \langle i, \langle n \rangle \rangle \to \langle i', \langle n' \rangle \rangle \) be a morphism in \( \Delta^1 \times \text{N}(\text{Fin}_*) \). Fix \( j' \in \langle n' \rangle \). If \( i = i' = 0 \), let \( \eta_{j'} \) be the identity map from \( D_{j'} = \bigotimes_{\alpha(j') = j'} C_j \) to itself. Otherwise, choose a trivial cofibration
   \[
   \eta_{j'} : \bigotimes_{\alpha(j') = j'} C_j \to D_{j'},
   \]
where \( D_{j'} \in \mathcal{A} \) is fibrant. Together these determine a map \( \overline{\alpha} : \langle i, C_1, \ldots, C_n \rangle \to \langle i', D_1, \ldots, D_{n'} \rangle \) in \( \mathcal{M}^\otimes \) lying over \( \alpha \). We claim that \( \overline{\alpha} \) is \( p \)-coCartesian. To prove this, we must show that for every morphism \( \beta : \langle n' \rangle \to \langle n'' \rangle \) in \( \text{Ass}^\otimes \), every \( i' \leq i'' \leq 1 \), and every object \((i'', E_1, \ldots, E_{n''}) \in \mathcal{M}^\otimes \), the induced map
   \[
   \text{Map}_{\mathcal{M}^\otimes}((i', D_1, \ldots, D_{n'}), (i'', E_1, \ldots, E_{n''})) \times_{\text{Hom}_{\text{Fin}_*} \{\langle n' \rangle, \langle n'' \rangle\}} \{\beta\}
   \]
   \[
   \text{Map}_{\mathcal{M}^\otimes}((i, C_1, \ldots, C_n), (i'', E_1, \ldots, E_{n''}))
   \]
4.1. ASSOCIATIVE ALGEBRAS

4.1.3.15 yields the following:

\[ \text{N}_{\text{Ass}}(\mathbf{A}^\infty) \rightarrow \mathbf{Ass}^\infty \]

\[ \text{is a homotopy equivalence of Kan complexes. Since each } E_{j''} \text{ is a fibrant object of } \mathbf{A}, \text{ it will suffice to show that the map} \]

\[ \eta : \bigotimes_{\beta(j')=j''} C_i \rightarrow \bigotimes_{(\beta \circ \alpha)(j)=j''} D'_j \]

\[ \text{is a weak equivalence of cofibrant in } \mathbf{A}. \text{ This follows from the observation that } \eta \text{ can be identified with the tensor product of the maps } \eta_{j''}, \text{ each of which is a weak equivalence between cofibrant objects of } \mathbf{A}. \]

**Variant 4.1.3.17.** Suppose that \( \mathbf{A} \) is a simplicial monoidal model category. Let \( \mathbf{A}^\infty \) denote the full subcategory of \( \mathbf{A} \) spanned by the fibrant-cofibrant objects. We regard \( \mathbf{A}^\infty \) as a simplicial colored operad as follows: given a finite set \( I \) of cardinality \( n \), we set

\[ \text{Mul}^\infty_{\mathbf{A}^\infty}(\{X_i\}_{i \in I}, Y) = \prod_{\alpha} \text{Map}_{\mathbf{A}}(\otimes_{1 \leq j \leq n} X_{\alpha(j)}, Y), \]

where the coproduct is taken over all bijective maps \( \alpha : \{1, \ldots, n\} \rightarrow I \) (equivalently, over all linear orders of \( I \)). We let \( \text{N}^\infty_{\text{Ass}}(\mathbf{A}^\infty) \) denote the operadic nerve of this simplicial colored operad. The proof of Proposition 4.1.3.15 yields the following:

1. The map \( \text{N}^\infty_{\text{Ass}}(\mathbf{A}^\infty) \rightarrow \mathbf{Ass}^\infty \) exhibits \( \text{N}^\infty_{\text{Ass}}(\mathbf{A}^\infty) \) as a monoidal \( \infty \)-category.

2. Let \( \text{N}^\infty_{\text{Ass}}(\mathbf{A}^c) \) denote the monoidal \( \infty \)-category associated to the discrete monoidal category \( \mathbf{A}^c \). Then there exists a monoidal functor \( \theta : \text{N}^\infty_{\text{Ass}}(\mathbf{A}^c) \rightarrow \text{N}^\infty_{\text{Ass}}(\mathbf{A}^\infty) \) which induces an equivalence of \( \infty \)-categories \( \text{N}(\mathbf{A}^c)[W^{-1}] \simeq \text{N}(\mathbf{A}^\infty) \), where \( W \) is the collection of weak equivalences in \( \mathbf{A}^c \) (in other words, the monoidal functor \( \theta \) exhibits \( \text{N}(\mathbf{A}^\infty) \) as the underlying \( \infty \)-category of \( \mathbf{A} \)).

We now describe an application of Variant 4.1.3.17:

**Example 4.1.3.18.** Let \( \mathbf{Op}_{\infty}^\infty \) denote the category of \( \infty \)-preoperads, endowed with the monoidal model structure of Proposition 2.2.5.7. It is easy to see that this monoidal structure is compatible with the simplicial structure on \( \mathbf{Op}_{\infty}^\infty \) (in the sense of Definition 4.1.3.8), so that \( \mathbf{Op}_{\infty}^\infty \) is a simplicial monoidal model category. Applying Variant 4.1.3.17, we obtain a coCartesian fibration of \( \infty \)-operads \( \text{N}^\infty_{\text{Ass}}(\mathbf{Op}_{\infty}^\infty) \rightarrow \mathbf{Ass}^\infty \). There is an obvious map from the simplicial colored operad \( \mathbf{Op}_{\infty}^\infty \) of Construction 2.2.5.12 to the simplicial colored operad \( \mathbf{Op}^\infty_{\mathbf{A}^\infty} \) of Construction 2.2.5.12, which determines a commutative diagram

\[ \begin{array}{ccc} \text{N}^\infty_{\text{Ass}}(\mathbf{Op}_{\infty}^\infty) & \longrightarrow & \mathbf{Ass}^\infty \\ \downarrow & & \downarrow \\ \mathbf{Op}(\infty)^\circ & \longrightarrow & \mathbf{N}(\text{Fin}^\ast). \end{array} \]

In fact, this is a homotopy pullback diagram: that is, it induces an equivalence of \( \infty \)-operads \( \text{N}^\infty_{\text{Ass}}(\mathbf{Op}_{\infty}^\infty) \rightarrow \mathbf{Ass}^\infty \times_{\mathbf{N}(\text{Fin}^\ast)} \mathbf{Op}(\infty)^\circ \). To see this, it suffices to observe that for any sequence of \( \infty \)-operads \( \{O_i^\circ\}_{1 \leq i \leq n} \) and any other \( \infty \)-operad \( O^\circ \), the canonical map

\[ \text{Mul}^F_{\mathbf{Op}^\infty_{\mathbf{A}^\infty}}(\{O_i^\circ\}, O^\circ) \rightarrow \text{Mul}^F_{\mathbf{Op}^\infty_{\mathbf{A}^\infty}}(\{O_i^\circ\}, O^\circ) \]

is a homotopy equivalence. In fact, this map is the inclusion of a fiber of the Kan fibration

\[ \text{Mul}^F_{\mathbf{Op}^\infty_{\mathbf{A}^\infty}}(\{O_i\}, O^\circ) \rightarrow \mathbf{N}(\mathcal{S}(\{1, \ldots, n\})) \]

and the base \( \mathbf{N}(\mathcal{S}(\{1, \ldots, n\})) \) is a contractible Kan complex.
Remark 4.1.3.19. The underlying ∞-category of the ∞-operad $N_{\text{Ass}}(\mathcal{P} \mathcal{O}_{\infty}^c)$ can be identified with $N(\mathcal{P} \mathcal{O}_{\infty}^c) \simeq \mathcal{O}_{\infty}$.

### 4.1.4 Rectification of Associative Algebras

Let $A$ be a monoidal model category. In §4.1.3, we saw that the underlying ∞-category $N(A^c) [W^{-1}]$ of $A$ admits a monoidal structure, so it makes sense to consider algebra objects $A \in \text{Alg}(N(A^c) [W^{-1}])$. In this case, we can think of $A$ as an object of $A$ equipped with a multiplication $m : A \otimes A \to A$ which is unital and associative up to coherent homotopy.

Our goal in this section is to prove a rectification result which asserts (under some mild hypotheses on $A$) that $A$ is equivalent to a strictly unital and associative algebra in the ordinary category $A$. More precisely, we will show that $\text{Alg}(N(A^c) [W^{-1}])$ is equivalent to the underlying ∞-category of a simplicial model category $\text{Alg}(A)$ whose objects are associative algebras in $A$. Our first step is to describe a model structure on the ordinary category $\text{Alg}(A)$. Here we adopt the convention that if $C$ is any monoidal category, then $\text{Alg}(C)$ denotes the category of associative algebra objects of $C$. Note that there is a canonical equivalence $N(\text{Alg}(C)) \simeq \text{Alg}(N(C))$.

In the arguments which follow, we will need to invoke the following hypothesis (formulated originally by Schwede and Shipley; see [127]):

**Definition 4.1.4.1 (Monoid Axiom).** Let $A$ be a combinatorial symmetric monoidal model category. Let $U$ be the collection of all morphisms of $A$ having the form $X \otimes \text{id}_X \otimes f \to X \otimes Y'$, where $f$ is a trivial cofibration, and let $\mathcal{U}$ denote the weakly saturated class of morphisms generated by $U$ (Definition T.A.1.2.2). We will say that $A$ satisfies the monoid axiom if every morphism of $\mathcal{U}$ is a weak equivalence in $A$.

**Remark 4.1.4.2.** Let $A$ be a combinatorial symmetric monoidal model category in which every object is cofibrant, and let $U$ and $\mathcal{U}$ be as in Definition 4.1.4.1. Then every morphism belonging to $U$ is a trivial cofibration. Since the collection of trivial cofibrations in $A$ is weakly saturated, we conclude that $A$ satisfies the monoid axiom.

We will need the following result of [127]:

**Proposition 4.1.4.3.** [Schwede-Shipley] Let $A$ be a combinatorial monoidal model category. Assume that either every object of $A$ is cofibrant, or that $A$ is a symmetric monoidal model category which satisfies the monoid axiom. Then:

1. The category $\text{Alg}(A)$ admits a combinatorial model structure, where:
   - $(W)$ A morphism $f : A \to B$ of algebra objects of $A$ is a weak equivalence if it is a weak equivalence when regarded as a morphism in $A$.
   - $(F)$ A morphism $f : A \to B$ of algebra objects of $A$ is a fibration if it is a fibration when regarded as a morphism in $A$.

2. The forgetful functor $\theta : \text{Alg}(A) \to A$ is a right Quillen functor.

3. If $A$ is equipped with a compatible simplicial structure, then $\text{Alg}(A)$ inherits the structure of a simplicial model category.

4. Suppose that every object of $A$ is cofibrant and that the collection of weak equivalences in $A$ is stable under filtered colimits. Then $\text{Alg}(A)$ is left proper.

Assuming Proposition 4.1.4.3 for the moment, we can now state our main result:
4.1. ASSOCIATIVE ALGEBRAS

Theorem 4.1.4.4. Let $A$ be a combinatorial monoidal model category. Assume either:

(A) Every object of $A$ is cofibrant.

(B) The model category $A$ is left proper, the class of cofibrations in $A$ is generated by cofibrations between cofibrant objects, the monoidal structure on $A$ is symmetric, and $A$ satisfies the monoid axiom.

Let $W$ be the collection of weak equivalences in $A^e$, and $W'$ the collection of weak equivalences in $\text{Alg}(A)^e$. Then the canonical map

$$N(\text{Alg}(A)^e)[W'^{-1}] \to \text{Alg}(N(A^e))[W^{-1}]$$

is an equivalence of $\infty$-categories.

Remark 4.1.4.5. In the situation of Proposition 4.1.4.3, assume that $A$ is a simplicial monoidal model category (in the sense of Definition 4.1.3.8). Then $\text{Alg}(A)$ inherits the structure of a simplicial model category. The simplicial structure on $\text{Alg}(A)$ can be described as follows: for any pair of algebras $A, B \in \text{Alg}(A)$, the mapping space $\text{Map}_{\text{Alg}(A)}(A, B)$ is the simplicial subset of $\text{Map}_A(A, B)$ characterized by the following property: a map of simplicial sets $K \to \text{Map}_A(A, B)$ factors through $\text{Map}_{\text{Alg}(A)}(A, B)$ if and only if the diagrams

$$\Delta^0 \times K \to \text{Map}_A(1, A) \times \text{Map}_e(A, B)$$

$$\text{Map}_A(A, B) \to \text{Map}_A(1, B)$$

$$K \to K \times K \to \text{Map}_A(A, B) \times \text{Map}_A(A, B) \to \text{Map}_A(A \otimes A, B \otimes B)$$

$$\Delta^0 \times K \to \text{Map}_A(A \otimes A, A) \times \text{Map}_A(A, B) \to \text{Map}_A(A \otimes A, B)$$

commute.

Example 4.1.4.6. Let $A$ be the category of symmetric spectra, as defined in [73]. Then $A$ admits several model structures which satisfy assumption (B) of Theorem 4.1.4.4. It follows that $N(A^e)$ is equivalent, as a monoidal $\infty$-category, to the $\infty$-category $\text{Sp}$ of spectra (endowed with the smash product monoidal structure; see §4.8.2). Using Theorem 4.1.4.4, we deduce that the $\infty$-category $\text{Alg}(\text{Sp})$ of associative algebra objects of $\text{Sp}$ is equivalent to the underlying $\infty$-category of $\text{Alg}(A)$.

Example 4.1.4.7. [\$\infty$-Categorical MacLane Coherence Theorem] Let $A$ be the category of marked simplicial sets (see §T.3.1). Then $A$ is a simplicial model category, which satisfies the hypotheses of Example 2.4.1.10. Using Theorem 1.3.4.20, we can identify the underlying $\infty$-category of $A$ with $N(A^e) \simeq \text{Cat}_\infty$, the $\infty$-category of $\infty$-categories. Proposition 2.4.2.5 implies that composition with the evident Cartesian structure $N^\otimes(A^e) \to N(A^e)$ induces an equivalence of $\infty$-categories $\text{Alg}(N(A^e)) \to \text{Mon}_{A^e}(\text{Cat}_\infty)$. Combining this observation with Theorem 4.1.4.4, we conclude that the $\infty$-category of monoid objects of $\text{Cat}_\infty$ is equivalent to the $\infty$-category underlying the category of strictly associative monoids in $A$. In other words, every monoidal $\infty$-category $\mathcal{C}$ is equivalent (as a monoidal $\infty$-category) to an $\infty$-category $\mathcal{C}'$ equipped with a strictly associative multiplication $\mathcal{C}' \times \mathcal{C}' \to \mathcal{C}'$ (so that we can regard $\mathcal{C}'$ as a simplicial monoid). We regard this assertion as an $\infty$-categorical analogue of MacLane’s coherence theorem, which asserts that every monoidal category is equivalent to a strict monoidal category (that is, a monoidal category in which the tensor product operation $\otimes$ is associative up to equality, and the associativity isomorphisms are simply the identity maps).

We now turn to the proof of Proposition 4.1.4.3.
Lemma 4.1.4.8. Let $A$ be a combinatorial monoidal model category, and let $N(A^e)[W^{-1}]$ be its underlying $\infty$-category. Then the induced tensor product on $N(A^e)[W^{-1}]$ preserves small colimits separately in each variable.

Proof. For each object $A \in A$, the operation of tensor product with $A$ (either on the left or on the right) determines a left Quillen functor from $A$ to itself. The desired result now follows from Corollary 1.3.4.26. □

Remark 4.1.4.9. Lemma 4.1.4.8 admits a converse. Suppose that $\mathcal{C}$ is a presentable $\infty$-category endowed with a monoidal structure, and that the associated bifunctor $\otimes: \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves small colimits separately in each variable. Then $\mathcal{C}$ is equivalent (as a monoidal $\infty$-category) to the underlying $\infty$-category of a combinatorial simplicial monoidal model category $A$. Since we will not need this fact, we will only give a sketch of proof.

First, we apply Example 4.1.4.7 to reduce to the case where $\mathcal{C}$ is a strict monoidal $\infty$-category; that is, $\mathcal{C}$ is a simplicial monoid. Now choose a regular cardinal $\kappa$ such that $\mathcal{C}$ is $\kappa$-accessible. Enlarging $\kappa$ if necessary, we may suppose that the full subcategory $\mathcal{C}^\kappa \subseteq \mathcal{C}$ spanned by the $\kappa$-compact objects contains the unit object of $\mathcal{C}$ and is stable under tensor products.

The $\infty$-category $\mathcal{C}^\kappa$ is essentially small. We define a sequence of simplicial subsets

$$\mathcal{D}(0) \subseteq \mathcal{D}(1) \subseteq \ldots \subseteq \mathcal{C}^\kappa$$

as follows. Let $\mathcal{D}(0) = \emptyset$, and for $i \geq 0$ let $\mathcal{D}(i + 1)$ be a small simplicial subcategory of $\mathcal{C}^\kappa$ which is categorically equivalent to $\mathcal{C}^\kappa$ and contains the submonoid of $\mathcal{C}^\kappa$ generated by $\mathcal{D}(i)$. Let $\mathcal{D} = \bigcup \mathcal{D}(i)$, so that $\mathcal{D}$ is a small simplicial submonoid of $\mathcal{C}^\kappa$ such that the inclusion $\mathcal{D} \subseteq \mathcal{C}^\kappa$ is a categorical equivalence.

The proof of Theorem T.5.5.1.1 shows that $\mathcal{C}$ can be identified with an accessible localization of $\mathcal{P}(\mathcal{D})$. According to Proposition T.5.1.1.1, we can identify $\mathcal{P}(\mathcal{D})$ with $N(A^o)$, where $A$ denotes the category $\mathcal{S}(\Delta)/\mathcal{P}$ endowed with the contravariant model structure (see §T.2.1.4). Let $L: \mathcal{P}(\mathcal{D}) \to \mathcal{C}$ be a localization functor, and let $\mathcal{B}$ be the category $\mathcal{S}(\Delta)/\mathcal{P}$ endowed with the following localized model structure:

(C) A morphism $\alpha: X \to Y$ in $\mathcal{S}(\Delta)/\mathcal{P}$ is a cofibration in $\mathcal{B}$ if and only if $\alpha$ is a monomorphism of simplicial sets.

(W) A morphism $\alpha: X \to Y$ in $\mathcal{S}(\Delta)/\mathcal{P}$ is a weak equivalence in $\mathcal{B}$ if and only if the $L(\beta)$ is an isomorphism in the homotopy category $h\mathcal{C}$, where $\beta$ denotes the corresponding morphism in $h\mathcal{P}(\mathcal{D}) \simeq hA$.

(F) A morphism $\alpha: X \to Y$ in $\mathcal{S}(\Delta)/\mathcal{P}$ is a fibration in $\mathcal{B}$ if and only if it has the right lifting property with respect to every morphism which is simultaneously a cofibration and a weak equivalence in $\mathcal{B}$.

Proposition T.A.3.7.3 implies that $\mathcal{B}$ is a (combinatorial) simplicial model category, and that the underlying $\infty$-category $N(B^o)$ is equivalent to $\mathcal{C}$.

The category $\mathcal{S}(\Delta)/\mathcal{P}$ is endowed with a monoidal structure, which may be described as follows: given a finite collection of objects $X_1, \ldots, X_n \in \mathcal{S}/\mathcal{P}$, we let $X_1 \otimes \ldots \otimes X_n$ denote the product $X_1 \times \ldots \times X_n$ of the underlying simplicial sets, mapping to $\mathcal{P}$ via the composition $X_1 \times \ldots \times X_n \to \mathcal{P}^n \to \mathcal{P}$, where the second map is given by the monoid structure on $\mathcal{P}$. It is not difficult to verify that this monoidal structure is compatible with the model structure on $\mathcal{B}$. Applying Variant 4.1.3.17, we deduce that $N(B^{o\otimes})$ determines a monoidal structure on $N(B^o) \simeq \mathcal{C}$. One can show that this monoidal structure coincides (up to equivalence) with the free monoidal structure on $\mathcal{C}$.

We now turn to the proof of Proposition 4.1.4.3.

Notation 4.1.4.10. Let $f: X \to X'$ and $g: Y \to Y'$ be morphisms in a monoidal category $A$ which admits pushouts. We define the pushout product of $i$ and $j$ to be the induced map

$$f \wedge g: (X \otimes Y') \coprod_{X \otimes Y} (X' \otimes Y) \to X' \otimes Y'.$$

The operation $\wedge$ endows the category $\text{Fun}([1], A)$ with a monoidal structure, which is symmetric if the monoidal structure on $A$ is symmetric.
Lemma 4.1.4.11. Let A be a combinatorial symmetric monoidal model category which satisfies the monoid axiom, and let $\overline{U}$ be as in Definition 4.1.4.1. Then:

1. If $f : X \to X'$ belongs to $\overline{U}$ and $Y$ is an object of $A$, then $f \otimes \text{id}_Y : X \otimes Y \to X' \otimes Y$ belongs to $\overline{U}$.

2. If $f, g \in \overline{U}$, then $f \wedge g \in \overline{U}$.

Proof. To prove (1), let $S$ denote the collection of all morphisms $f$ in $A$ such that $f \otimes \text{id}_Y$ belongs to $\overline{U}$. It is easy to see that $S$ is weakly saturated. It will therefore suffice to show that $U \subseteq S$, which is obvious.

To prove (2), we use the same argument. Fix $g$, and let $S'$ be the set of all morphisms $f \in A$ such that $f \wedge g$ belongs to $\overline{U}$. We wish to prove that $U \subseteq S'$. Since $S'$ is weakly saturated, it will suffice to show that $U \subseteq S'$. In other words, we may assume that $f$ is of the form $f_0 \otimes \text{id}_A$, where $f_0$ is a trivial cofibration in $A$. Similarly, we may assume that $g = g_0 \otimes \text{id}_B$. Then $f \wedge g = (f_0 \wedge g_0) \otimes (\text{id}_A \otimes \text{id}_B)$, which belongs to $U$ since $f_0 \wedge g_0$ is a trivial cofibration in $A$.

Lemma 4.1.4.12. Let $A$ be a monoidal model category. Suppose given commutative diagrams

$$
\begin{array}{ccc}
A & \to & B \\
\downarrow & & \downarrow \\
A' & \to & B'
\end{array}
\quad
\begin{array}{ccc}
X & \to & Y \\
\downarrow & & \downarrow \\
X' & \to & Y'
\end{array}
$$

where every object is cofibrant, the horizontal arrows are cofibrations, and the vertical arrows are weak equivalences. Then in the induced diagram

$$
(A \otimes Y) \coprod_{A \otimes X} (B \otimes X) \to B \otimes Y
$$

$$
(A' \otimes Y') \coprod_{A' \otimes X'} (B' \otimes X') \to B' \otimes Y'
$$

has the same properties.

Proof. The assertion that the horizontal arrows are cofibrations follows immediately from the definition of a monoidal model category. Since every object appearing in either of the original diagrams, we deduce that each of the morphisms

$$
\begin{array}{ccc}
A \otimes X & \to & A' \otimes X' \\
B \otimes X & \to & B' \otimes X'
\end{array}
\quad
\begin{array}{ccc}
A \otimes Y & \to & A' \otimes Y' \\
B \otimes Y & \to & B' \otimes Y'
\end{array}
$$

is a weak equivalence between cofibrant objects. We obtain a weak equivalence of cofibrant diagrams

$$
\begin{array}{ccc}
A \otimes Y & \leftrightarrow & A \otimes X & \to & B \otimes X \\
\downarrow & & \downarrow & & \downarrow \\
A' \otimes Y' & \leftrightarrow & A' \otimes X' & \to & B' \otimes X',
\end{array}
$$

from which we obtain (by passing to the colimit) a weak equivalence of cofibrant objects $(A \otimes Y) \coprod_{A \otimes X} (B \otimes X) \to (A' \otimes Y') \coprod_{A' \otimes X'} (B' \otimes X')$ as desired. \hfill \square

Proof of Proposition 4.1.4.3. We first observe that the category $\text{Alg}(A)$ is presentable (this follows, for example, from Corollary 3.2.3.5). Recall that a collection $S$ of morphisms in a presentable category $\mathcal{C}$ is weakly saturated if it is stable under pushouts, retracts, and transfinite composition (see Definition T.A.1.2.2); we will say that $S$ is generated by a subset $S_0 \subseteq S$ if $S$ is the smallest weakly saturated collection of morphisms containing $S_0$. 

Since \( \mathcal{C} \) is combinatorial, there exists a (small) collection of morphisms \( I = \{ i_\alpha : C \to C' \} \) which generates the class of cofibrations in \( \mathbf{A} \), and a (small) collection of morphisms \( J = \{ j_\alpha : D \to D' \} \) which generates the class of trivial cofibrations in \( \mathbf{A} \).

Let \( F : \mathbf{A} \to \text{Alg}(\mathbf{A}) \) be a left adjoint to the forgetful functor. Let \( \overline{F(I)} \) be the weakly saturated class of morphisms in \( \text{Alg}(\mathbf{A}) \) generated by \( \{ F(i) : i \in I \} \), and let \( \overline{F(J)} \) be defined similarly. Unwinding the definitions, we see that a morphism in \( \text{Alg}(\mathbf{A}) \) is a trivial fibration if and only if it has the right lifting property with respect to \( F(i) \), for every \( i \in I \). Invoking the small object argument, we deduce that every morphism \( f : A \to C \) in \( \text{Alg}(\mathbf{A}) \) admits a factorization \( A \xrightarrow{f_i} B \xrightarrow{f''} C \) where \( f' \in \overline{F(I)} \) and \( f'' \) is a trivial fibration. Similarly, we can find an analogous factorization where \( f' \in \overline{F(J)} \) and \( f'' \) is a fibration.

Using a standard argument, we may reduce the proof of (1) to the problem of showing that every morphism belonging to \( \overline{F(J)} \) is a weak equivalence in \( \text{Alg}(\mathbf{A}) \). If \( \mathbf{A} \) is symmetric and satisfies the monoid axiom, then let \( \overline{\mathcal{U}} \) be as in Definition 4.1.4.1; otherwise let \( \overline{\mathcal{U}} \) be the collection of all trivial cofibrations in \( \mathbf{A} \). Let \( S \) be the collection of all morphisms in \( \text{Alg}(\mathbf{A}) \) such that the induced map in \( \mathbf{A} \) belongs to \( \overline{\mathcal{U}} \). Then \( S \) is weakly saturated, and every element of \( S \) is a weak equivalence. To complete the proof, it will suffice to show that \( F(J) \subseteq S \). In other words, we must prove:

\[
(*) \text{ Let } \quad \begin{array}{ccc}
F(C) & \xrightarrow{F(i)} & F(C') \\
\downarrow & & \downarrow \\
A & \xrightarrow{f} & A'
\end{array}
\]

be a pushout diagram in \( \text{Alg}(\mathbf{A}) \). If \( i \) is a trivial cofibration in \( \mathbf{A} \), then \( f \in S \).

Let \( \emptyset \) be an initial object of \( \mathbf{A} \), and let \( j : \emptyset \to A \) be the unique morphism. We now observe that \( A' \) can be obtained as the direct limit of a sequence

\[
A = A^{(0)} \xrightarrow{f_1} A^{(1)} \xrightarrow{f_2} \ldots
\]

of objects of \( \mathbf{A} \), where each \( f_n \) is a pushout of \( j \wedge i \wedge j \wedge \ldots \wedge i \wedge j \); here the factor \( i \) appears \( n \) times. If every object of \( \mathbf{A} \) is cofibrant, then we conclude that \( f_n \) is a trivial cofibration using the definition of a monoidal model category. If the monoidal structure on \( \mathbf{A} \) is symmetric and satisfies the monoid axiom, then repeated application of Lemma 4.1.4.11 shows that \( f_n \in \overline{\mathcal{U}} \). Since \( \overline{\mathcal{U}} \) is weakly saturated, it follows that \( f \in S \) as desired. This completes the proof of (1).

Assertion (2) is obvious. To prove (3), we observe both \( \mathbf{A} \) and \( \text{Alg}(\mathbf{A}) \) are cotensored over simplicial sets, and that we have canonical isomorphisms \( \theta(A^K) \simeq \theta(A)^K \) for \( A \in \text{Alg}(\mathbf{A}) \), \( K \in \text{Set}_{\Delta} \). To prove that \( \text{Alg}(\mathbf{A}) \) is a simplicial model category, it will suffice to show that \( \text{Alg}(\mathbf{A}) \) is cotensored over simplicial sets, and that given a fibration \( i : A \to A' \) in \( \text{Alg}(\mathbf{A}) \) and a cofibration \( j : K \to K' \) in \( \text{Set}_{\Delta} \), the induced map \( A^K \to A^K \times_{A^K} A'^K \) is a fibration, trivial if either \( i \) or \( j \) is a fibration. The second claim follows from the fact that \( \theta \) detects fibrations and trivial fibrations. For the first, it suffices to prove that for \( K \in \text{Set}_{\Delta} \), the functor \( A \to A^K \) has a left adjoint; this follows from the adjoint functor theorem.

We now prove (4). Let \( T \) be the collection of all morphisms \( \alpha : X \to Y \) in \( \text{Alg}(\mathbf{A}) \) with the following property: for every pushout diagram

\[
\begin{array}{ccc}
X & \xrightarrow{\alpha} & Y \\
\downarrow & & \downarrow \\
A & \xrightarrow{\beta} & A' \\
\downarrow & & \downarrow \\
B & \xrightarrow{\beta'} & B'
\end{array}
\]
4.1. ASSOCIATIVE ALGEBRAS

if \( \beta \) is a weak equivalence, then \( \beta' \) is a weak equivalence. To prove that \( \mathbf{A} \) is left proper, it will suffice to show that every fibration belongs to \( T \). Using the assumption that the collection of weak equivalences in \( \mathbf{A} \) is stable under filtered colimits, we deduce that \( T \) is a weakly saturated class of morphisms. It will therefore suffice to show that \( T \) contains every generating fibration of the form \( F(i) : F(x) \to F(y) \), where \( i : x \to y \) is a fibration in \( \mathbf{A} \). The algebra objects \( A' \) and \( B' \) can be defined as the direct limit of sequences

\[
A = A^{(0)} \xrightarrow{f_1} A^{(1)} \xrightarrow{f_2} \ldots
\]

\[
B = B^{(0)} \xrightarrow{g_1} B^{(1)} \xrightarrow{g_2} \ldots
\]
as in the proof of \("\). Since the collection of weak equivalences in \( \mathbf{A} \) is stable under filtered colimits, it will suffice to show that each of the maps \( \beta_k : A^{(k)} \to B^{(k)} \) is a weak equivalence. For \( k = 0 \) there is nothing to prove; in the general case we work by induction on \( k \). We have a map between the homotopy pushout diagrams

\[
\begin{array}{ccc}
K & \xrightarrow{f'_k} & A \otimes y \otimes \ldots \otimes y \otimes A \\
\downarrow f_k & & \downarrow \\
A^{(k-1)} & \xrightarrow{f_k} & A^{(k)}
\end{array}
\quad \quad \quad
\begin{array}{ccc}
L & \xrightarrow{g'_k} & B \otimes y \otimes \ldots \otimes y \otimes B \\
\downarrow g_k & & \downarrow \\
B^{(k-1)} & \xrightarrow{g_k} & B^{(k)}
\end{array}
\]

Consequently, to prove that \( \beta_k \) is a weak equivalence, it will suffice to show that \( \beta_{k-1} \) is a weak equivalence (which follows from the inductive hypothesis) and that the maps

\[
K \to L \quad A \otimes y \otimes \ldots \otimes y \otimes A \to B \otimes y \otimes \ldots \otimes y \otimes B
\]

are weak equivalences, which follows from Lemma 4.1.4.12. \( \square \)

We now turn to the proof of Theorem 4.1.4.4. The main point is to establish the following:

**Lemma 4.1.4.13.** Let \( \mathbf{A} \) be a combinatorial monoidal model category and let \( \mathcal{C} \) be a small category such that \( N(\mathcal{C}) \) is sifted (Definition T.5.5.8.1). Assume either that every object of \( \mathbf{A} \) is cofibrant, or that \( \mathbf{A} \) satisfies the following pair of conditions:

(A) The monoidal structure on \( \mathbf{A} \) is symmetric, and \( \mathbf{A} \) satisfies the monoid axiom.

(B) The model category \( \mathbf{A} \) is left proper and the class of cofibrations in \( \mathbf{A} \) is generated by cofibrations between cofibrant objects (this is automatic if every object of \( \mathbf{A} \) is cofibrant).

Let \( W \) be the collection of weak equivalences in \( \mathbf{A}^c \) and \( W' \) the collection of weak equivalences in \( \text{Alg}(\mathbf{A})^c \). Then the forgetful functor \( N(\text{Alg}(\mathbf{A})^c)[W'^{-1}] \to N(\mathbf{A}^c)[W^{-1}] \) preserves \( N(\mathcal{C}) \)-indexed colimits.

**Proof.** In view of Propositions 1.3.4.24 and 1.3.4.25, it will suffice to show that the forgetful functor \( \theta : \text{Alg}(\mathbf{A}) \to \mathbf{A} \) preserves homotopy colimits indexed by \( \mathcal{C} \). Let us regard \( \text{Alg}(\mathbf{A})^c \) and \( \mathbf{A}^c \) as endowed with the projective model structure (see §T.A.3.3). Let \( F : \mathbf{A}^c \to \mathbf{A} \) and \( \text{Alg}(\mathbf{A})^c \to \text{Alg}(\mathbf{A}) \) be cofibrant functors, and let \( \theta^c : \text{Alg}(\mathbf{A})^c \to \mathbf{A}^c \) be given by composition with \( \theta \). Since \( N(\mathcal{C}) \) is sifted, there is a canonical isomorphism of functors \( \alpha : F \circ \theta^c \simeq \theta \circ \text{Alg} \). We wish to prove that this isomorphism persists after deriving all of the relevant functors. Since \( \theta \) and \( \theta^c \) preserve weak equivalences, they can be identified with their right derived functors. Let \( LF \) and \( LF_{\text{Alg}} \) be the left derived functors of \( F \) and \( \text{Alg} \), respectively. Then \( \alpha \) induces a natural transformation \( \theta^c \circ LF \to LF_{\text{Alg}} \); we wish to show that \( \alpha \) is an isomorphism.

Let \( A : \mathcal{C} \to \text{Alg}(\mathbf{A}) \) be a projectively cofibrant object of \( \text{Alg}(\mathbf{A})^c \); we must show that the natural map

\[
LF(\theta^c(A)) \to \theta(LF_{\text{Alg}}(A)) \simeq \theta(F_{\text{Alg}}(A)) \simeq F(\theta^c(A))
\]

is a weak equivalence in \( \mathbf{A} \).

Let us say that an object \( X \in \mathbf{A}^c \) is good if each of the objects \( X(C) \in \mathbf{A} \) is cofibrant, the object \( F(X) \in \mathbf{A} \) is cofibrant, and the natural map \( LF(X) \to F(X) \) is a weak equivalence in \( \mathbf{A} \); in other words, if
the colimit of $X$ is also a homotopy colimit of $X$. To complete the proof, it will suffice to show that $\theta^c(A)$ is good, whenever $A$ is a projectively cofibrant object of $\text{Alg}(A)^c$. This is not obvious, since $\theta^c$ is a right Quillen functor and does not preserve projectively cofibrant objects in general (note that we have not yet used the full strength of our assumption that $N(\mathcal{C})$ is sifted). To continue the proof, we will need a relative version of the preceding condition. We will say that a morphism $f : X \to Y$ in $A^c$ is good if the following conditions are satisfied:

(i) The objects $X, Y \in A^c$ are good.

(ii) For each $C \in \mathcal{C}$, the induced map $X(C) \to Y(C)$ is a cofibration in $A$.

(iii) The map $F(X) \to F(Y)$ is a cofibration in $A$.

We now make the following observations:

(1) The collection of good morphisms is stable under transfinite composition. More precisely, suppose given an ordinal $\alpha$ and a direct system of objects $\{X^\beta\}_{\beta < \alpha}$ of $A^c$. Suppose further that for every $0 < \beta < \alpha$, the map $\lim\{X^\gamma\}_{\gamma < \beta} \to X^\beta$ is good. Then the induced map $X^0 \to \lim\{X^\beta\}_{\beta < \alpha}$ is good. The only nontrivial point is to verify that the object $X = \lim\{X^\beta\}_{\beta < \alpha}$ is good. For this, we observe $X$ is a homotopy colimit of the system $\{X^\beta\}$ (in virtue of (ii)), while $F(X)$ is a homotopy colimit of the system $\{F(X^\beta)\}$ (in virtue of (iii)), and that the collection of homotopy colimit diagrams is stable under homotopy colimits.

(2) Suppose given a pushout diagram

$$
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow & & \downarrow \\
X' & \xrightarrow{f'} & Y'
\end{array}
$$

in $A^c$. If $f$ is good and $X'$ is good, then $f'$ is good. Once again, the only nontrivial point is to show that $Y'$ is good. To see this, we observe that our hypothesis imply that $Y'$ is homotopy pushout of $Y$ with $X'$ over $X$. Similarly, $F(Y')$ is a homotopy pushout of $F(Y)$ with $F(X')$ over $F(X)$. We now invoke once again the fact that the class of homotopy colimit diagrams is stable under homotopy colimits.

(3) Let $F : \mathcal{C} \to A$ be a constant functor whose value is a cofibrant object of $A$. Then $F$ is good. This follows from the fact that $N(\mathcal{C})$ is weakly contractible (use Propositions 1.3.4.24 and T.5.5.8.7).

(4) Every projectively cofibrant object of $A^c$ is good. Every projective cofibration between projectively cofibrant objects of $A^c$ is good.

(5) If $X$ and $Y$ are good objects of $A^c$, then $X \otimes Y$ is good. To prove this, we first observe that the collection of cofibrant objects of $A$ is stable under tensor products. Because $N(\mathcal{C})$ is sifted, Proposition 1.3.4.24 supplies a chain of isomorphisms in $hA$:

$$LF(X \otimes Y) \simeq LF(X) \otimes LF(Y) \simeq F(X) \otimes F(Y) \simeq F(X \otimes Y).$$

(6) Let $f : X \to X'$ be a good morphism in $A^c$, and let $Y$ be a good object of $A^c$. Then the morphism $f \otimes 1_Y$ is good. Condition (i) follows from (5), condition (ii) follows from the fact that tensoring with each $Y(C)$ preserves cofibrations (since $Y(C)$ is cofibrant), and condition (iii) follows by applying the same argument to $F(Y)$ (and invoking the fact that $F$ commutes with tensor products).
Let $f : X \to X'$ and $g : Y \to Y'$ be good morphisms in $\mathbf{A}^c$. Then

$$f \land g : (X \otimes Y') \coprod_{X \otimes Y} (X' \otimes Y) \to X' \otimes Y'$$

is good. Condition (ii) follows immediately from the fact that $\mathbf{A}$ is a monoidal model category. Condition (iii) follows from the same argument, together with the observation that $F$ commutes with pushouts and tensor products. Condition (i) follows by combining (5), (6), and (2).

We observe that our assumption (B) implies an analogous result for $\mathbf{A}^c$:

(B') The collection of all projective cofibrations in $\mathbf{A}^c$ is generated by projective cofibrations between projectively cofibrant objects.

Let $T : \mathbf{A}^c \to \text{Alg}(\mathbf{A})^c$ be a left adjoint to $\theta^c$. Using the small object argument and (B'), we conclude that for every projectively cofibrant object $A \in \text{Alg}(\mathbf{A})^c$ there exists a transfinite sequence $\{A^\beta\}_{\beta \leq \alpha}$ in $\text{Alg}(\mathbf{A})^c$ with the following properties:

(a) The object $A^0$ is initial in $\text{Alg}(\mathbf{A})^c$.

(b) The object $A$ is a retract of $A^\alpha$.

(c) If $\lambda \leq \alpha$ is a limit ordinal, then $A^\lambda \simeq \text{colim}\{A^\beta\}_{\beta \leq \lambda}$.

(d) For each $\beta < \alpha$, there is a pushout diagram

$$
\begin{array}{ccc}
T(X') & \xrightarrow{T(f)} & T(X) \\
\downarrow & & \downarrow \\
A^\beta & \xrightarrow{v} & A^{\beta+1}
\end{array}
$$

where $f$ is a projective cofibration between projectively cofibrant objects of $\mathbf{A}^c$.

We wish to prove that $\theta^c(A)$ is good. In view of (b), it will suffice to show that $\theta^c(A^\alpha)$ is good. We will prove a more general assertion: for every $\gamma \leq \beta \leq \alpha$, the induced morphism $u_{\gamma, \beta} : \theta^c(A^\gamma) \to \theta^c(A^\beta)$ is good. The proof is by induction on $\beta$. If $\beta = 0$, then we are reduced to proving that $\theta^c(A^0)$ is good. This follows from (a) and (3). If $\beta$ is a nonzero limit ordinal, then the desired result follows from (c) and (1). It therefore suffices to treat the case where $\beta = \beta' + 1$ is a successor ordinal. Moreover, we may suppose that $\gamma = \beta'$: if $\gamma < \beta'$, then we observe that $u_{\gamma, \beta} = u_{\beta', \beta} \circ u_{\gamma, \beta'}$ and invoke (1), while if $\gamma > \beta'$, then $\gamma = \beta$ and we are reduced to proving that $\theta^c(A^\beta)$ is good, which follows from the assertion that $u_{\beta', \beta}$ is good. We are now reduced to proving the following:

(*) Let

$$
\begin{array}{ccc}
T(X') & \xrightarrow{T(f)} & T(X) \\
\downarrow & & \downarrow \\
B' & \xrightarrow{v} & B
\end{array}
$$

be a pushout diagram in $\text{Alg}(\mathbf{A})^c$, where $f : X' \to X$ is a projective cofibration between projectively cofibrant objects of $\mathbf{A}^c$. If $\theta^c(B')$ is good, then $\theta^c(v)$ is good.

To prove (*), we set $Y = \theta^c(B) \in \mathbf{A}^c$, $Y' = \theta^c(B') \in \mathbf{A}^c$. Let $g : \emptyset \to Y'$ the unique morphism, where $\emptyset$ denotes an initial object of $\mathbf{A}^c$. As in the proof of Proposition 4.1.4.3, $Y$ can be identified with the colimit of a sequence

$$Y^{(0)} \xrightarrow{w_1} Y^{(1)} \xrightarrow{w_2} \ldots$$
where $Y^{(0)} = Y'$, and $w_k$ is a pushout of the morphism $f^{(k)} = g \wedge f \wedge g \ldots \wedge f \wedge g$, where the factor $f$ appears $k$ times. In view of (1) and (2), it will suffice to prove that each $f^{(k)}$ is a good morphism. Since $Y'$ is good, we conclude immediately that $g$ is good. It follows from (4) that $f$ is good. Repeated application of (7) allows us to deduce that $f^{(k)}$ is good, and to conclude the proof.

We are now ready to prove our main result.

**Proof of Theorem 4.1.4.4.** Consider the diagram

\[
\begin{array}{ccc}
N(\text{Alg}(A)^c)[W^{-1}] & \longrightarrow & \text{Alg}(N(A)[W^{-1}]) \\
G & & \downarrow G'
\end{array}
\]

It will suffice to show that this diagram satisfies the hypotheses of Corollary 4.7.4.16:

(a) The $\infty$-categories $N(\text{Alg}(A)^c)[W^{-1}]$ and $\text{Alg}(N(A)^c)[W^{-1}]$ admit geometric realizations of simplicial objects. In fact, both of these $\infty$-categories are presentable. For $N(\text{Alg}(A)^c)[W^{-1}]$, this follows from Proposition 1.3.4.22. For $\text{Alg}(N(A)^c)$, we first observe that $N(A)^c)[W^{-1}]$ is presentable (Proposition 1.3.4.22) and that the tensor product preserves colimits separately in each variable (Lemma 4.1.4.8), and apply Corollary 3.2.3.5.

(b) The functors $G$ and $G'$ admit left adjoints $F$ and $F'$. The existence of a left adjoint to $G$ is clear, and the existence of a left adjoint to $G'$ follows from Corollary 3.1.3.5.

(c) The functor $G'$ is conservative and preserves geometric realizations of simplicial objects. This follows from Proposition 3.2.3.1 and Lemma 3.2.2.6.

(d) The functor $G$ is conservative and preserves geometric realizations of simplicial objects. The first assertion is immediate from the definition of the weak equivalences in $\text{Alg}(A)$, and the second follows from Lemma 4.1.4.13.

(e) The canonical map $G' \circ F' \to G \circ F$ is an equivalence of functors. This follows from the observation that both sides induce, on the level of homotopy categories, the free algebra functor $C \mapsto \coprod_{n \geq 0} C \otimes^n$ (Proposition 4.1.1.14).

---

**Corollary 4.1.4.14.** Let $A$ be combinatorial model category. Assume that:

(i) The Cartesian product functor endows $A$ with the structure of a monoidal model category.

(ii) The model category $A$ is left proper and the class of cofibrations is generated by cofibrations between cofibrant objects.

(iii) The Cartesian product functor on $A$ satisfies the monoid axiom.

Let $G : \text{Alg}(A) \to A^\Delta^{op}$ be the functor which assigns to each algebra object of $A$ the corresponding monoid object. Then:

1. The functor $G$ admits a left adjoint $F$.

2. The functors $F$ and $G$ determine a Quillen adjunction between $\text{Alg}(A)$ and $A^\Delta^{op}$, where the latter category is endowed with the projective model structure.
4.2. LEFT AND RIGHT MODULES

(3) The right derived functor $RG$ is fully faithful, and its essential image in the homotopy category of $A\Delta^{op}$ consists of those simplicial objects $A_\bullet$ of $A$ which determine monoid objects of the homotopy category $hA$.

**Remark 4.1.4.15.** Conditions (ii) and (iii) in the statement of Corollary 4.1.4.14 are automatic if we assume that every object of $A$ is cofibrant.

**Proof.** Assertion (1) follows from the adjoint functor theorem, since $G$ is an accessible functor which commutes with small limits. Assertion (2) is clear, since $G$ preserves weak equivalences and fibrations. To prove (3), it will suffice to show that the induced map of $\infty$-categories $F' : N((A\Delta^{op})^e)[W^{-1}] \to N(\text{Alg}(A)^e)[W'^{-1}]$ admits a fully faithful right adjoint $G''$, whose essential image is the collection of diagrams $\Delta^{op} \to A$ which determine monoid objects in the homotopy category $hA$. Here $W$ and $W'$ denote the collections of weak equivalences between cofibrant objects in $A\Delta^{op}$ and $\text{Alg}(A)$, respectively.

We have a homotopy commutative diagram

$$
\begin{array}{ccc}
N(\text{Alg}(A)^e)[W'^{-1}] & \to & N((A\Delta^{op})^e)[W^{-1}] \\
\downarrow p & & \downarrow q \\
\text{Alg}(N(A^e)[V^{-1}]) & \to & \text{Fun}(N(\Delta^{op}), N(A^e)[V^{-1}]),
\end{array}
$$

where $V$ is the collection of weak equivalences in $A^e$, the map $p$ is the categorical equivalence of Theorem 4.1.4.4, and $q$ is the categorical equivalence supplied by Proposition 1.3.4.25. It will therefore suffice to show that $G''$ is fully faithful, and that its essential image is the class of monoid objects of $N(A^e)[W^{-1}]$. This follows immediately Propositions 4.1.2.6 and 2.4.2.5.

### 4.2 Left and Right Modules

Let $\mathcal{C}$ be a monoidal category with unit object $1$ and let $A$ be an associative algebra object of $\mathcal{C}$. A *left $A$-module* in $\mathcal{C}$ is an object $M \in \mathcal{C}$ equipped with an action map $a : A \otimes M \to M$ such that the following diagrams commute

$$
\begin{array}{ccc}
A \otimes A \otimes M & \xrightarrow{m \otimes \text{id}} & A \otimes M \\
\downarrow \text{id} \otimes a & & \downarrow a \\
A \otimes M & \xrightarrow{a} & M
\end{array}
\quad
\begin{array}{ccc}
1 \otimes M & \xrightarrow{u \otimes \text{id}} & A \otimes M \\
\downarrow a & & \downarrow M
\end{array}
$$

where $m : A \otimes A \to A$ and $u : 1 \to A$ denote the multiplication and unit of $A$, respectively. The collection of all left $A$-modules can be organized into a category $\text{LMod}_A(\mathcal{C})$.

Our goal in this section is to generalize the theory of left modules to the $\infty$-categorical setting. Recall that if $\mathcal{C}^\otimes$ is a symmetric monoidal $\infty$-category (with underlying $\infty$-category $\mathcal{C}$), then an associative algebra object of $\mathcal{C}$ is defined to be a map of $\infty$-operads $\text{Ass}^\otimes \to \mathcal{C}^\otimes$ (Definition 4.1.1.10). In §4.2.1, we will introduce a larger $\infty$-operad $\mathcal{L}M^\otimes$, which contains $\text{Ass}^\otimes$ as a full subcategory. If $A : \text{Ass}^\otimes \to \mathcal{C}^\otimes$ is an associative algebra object of $\mathcal{C}$, then we can define a left $A$-module to be a map of $\infty$-operads $M : \mathcal{L}M^\otimes \to \mathcal{C}^\otimes$ such that $M|_\text{Ass}^\otimes = A$.

If $A$ is an associative algebra of a symmetric monoidal $\infty$-category $\mathcal{C}^\otimes$, then the collection of all left $A$-module objects of $\mathcal{C}$ can be organized into an $\infty$-category, which we will denote by $\text{LMod}_A(\mathcal{C})$. In practice, it is often useful to know that $A$-module structures survive as we perform various categorical constructions in $\mathcal{C}$. In §4.2.3, we will describe several instances of this phenomenon, by showing that (under some mild hypotheses) the $\infty$-category $\text{LMod}_A(\mathcal{C})$ admits limits and colimits which are preserved by the forgetful functor $\text{LMod}_A(\mathcal{C}) \to \mathcal{C}$. To prove assertions of this type, it will be useful to adopt an alternative definition of left module (Definition 4.2.2.10) which we describe in §4.2.2, building on the ideas of §4.1.2.
The theory of left modules developed in this section can be regarded as a generalization of the classical theory of left modules in the following sense: if \( \mathcal{C} \) is a symmetric monoidal category and \( A \) is an associative algebra object of \( \mathcal{C} \), then we have an equivalence of \( \infty \)-categories

\[
\theta : N(\text{LMod}_A(\mathcal{C})) \to \text{LMod}_A(N(\mathcal{C})).
\]

where the \( \infty \)-category \( N(\mathcal{C}) \) inherits a symmetric monoidal structure from \( \mathcal{C} \) (see Example 2.1.2.21) and we identify \( A \) with the corresponding associative algebra object of \( N(\mathcal{C}) \). More generally, if \( \mathcal{C} \) is a fibrant simplicial category, then we can define a functor \( \theta \) as indicated above (where \( N(\mathcal{C}) \) now denotes the homotopy coherent nerve of \( \mathcal{C} \)), but it need not be an equivalence: objects of \( \text{LMod}_A(N(\mathcal{C})) \) can be thought of as objects \( M \in \mathcal{C} \) together with a coherently associative left action of \( A \) on \( M \), which cannot always be rectified to a strictly associative action of \( A \) on \( M \). In §4.3.3, we will see that this rectification can often be achieved when \( \mathcal{C} \) is the underlying \( \infty \)-category of a monoidal model category; in these cases, \( \theta \) is an equivalence when restricted to the subcategory of cofibrant objects of \( \text{LMod}_A(\mathcal{C}) \) (see Theorem 4.3.3.17 for a precise statement). The key to the proof is a structure theorem for free modules (Proposition 4.2.4.2) which we will prove in §4.2.4, using the general machinery developed in Chapter 3.

### 4.2.1 The \( \infty \)-Operad \( \text{LM}^\otimes \)

Our goal in this section is to lay the foundations for an \( \infty \)-categorical theory of left modules over associative algebras. As a first step, we recast the classical theory of left modules using the language of colored operads.

**Definition 4.2.1.1.** We define a colored operad \( \text{LM} \) as follows:

(i) The set of objects of \( \text{LM} \) has two elements, which we will denote by \( a \) and \( m \).

(ii) Let \( \{X_i\}_{i \in I} \) be a finite collection of objects of \( \text{LM} \) and let \( Y \) be another object of \( \text{LM} \). If \( Y = a \), then \( \text{Mul}_{\text{LM}}(\{X_i\}, Y) \) is the collection of all linear orderings of \( I \) provided that each \( X_i = a \), and is empty otherwise. If \( Y = m \), then \( \text{Mul}_{\text{LM}}(\{X_i\}, Y) \) is the collection of all linear orderings \( \{i_1 < \cdots < i_n\} \) on the set \( I \) such that \( X_{i_n} = m \) and \( X_{i_j} = a \) for \( j < n \) (by convention, we agree that this set is empty if \( I \) is empty).

(iii) The composition law on \( \text{LM} \) is determined by the composition of linear orderings, as described in Definition 4.1.1.1.

**Remark 4.2.1.2.** Restricting our attention to the object \( a \in \text{LM} \), we obtain a sub-colored operad of \( \text{LM} \), which is isomorphic to the colored operad \( \text{Ass} \) of Definition 4.1.1.1. We will often abuse notation by identifying \( \text{Ass} \) with this sub-colored operad of \( \text{LM} \).

**Remark 4.2.1.3.** If \( \mathcal{C} \) is a symmetric monoidal category and \( F : \text{LM} \to \mathcal{C} \) is a map of colored operads, then \( F|_{\text{Ass}} \) is a map of colored operads \( \text{Ass} \to \mathcal{C} \), which we can identify with an associative algebra object \( F(a) = A \in \mathcal{C} \) (see Remark 4.1.1.2). Let \( M = F(m) \in \mathcal{C} \). The unique operation \( \phi \in \text{Mul}_{\text{LM}}(\{a, m\}, m) \) determines a map \( F(\phi) : A \otimes M \to M \). It is not difficult to see that \( F(\phi) \) exhibit \( M \) as a left \( A \)-module.

Conversely, suppose we are given a map of colored operads \( F_0 : \text{Ass} \to \mathcal{C} \) corresponding to an associative algebra object \( A \in \mathcal{C} \), and \( a : A \otimes M \to M \) be a map which exhibits \( M \) as a left \( A \)-module. To every finite linearly ordered set \( I \), we can associate a map

\[
A^\otimes I \otimes M \to A \otimes M \xrightarrow{a} M,
\]

where the first map is given by the associative algebra structure on \( A \). This construction determines a map of colored operads \( F : \text{LM} \to \mathcal{C} \) extending \( F_0 \), such that \( F(m) = M \).

We can summarize the above discussion as follows: if \( F_0 : \text{Ass} \to \mathcal{C} \) classifies an associative algebra object \( A \in \mathcal{C} \), then giving a left \( A \)-module is equivalent to giving a map of colored operads \( F : \text{LM} \to \mathcal{C} \) which extends \( F_0 \).
Remark 4.2.1.4. Our notation for the objects of \( \text{LM} \) is motivated by Remark 4.2.1.3: a map of colored operads from \( \text{LM} \) to a symmetric monoidal category \( \mathcal{C} \) carries \( a \) to an associative algebra in \( \mathcal{C} \), and \( m \) to a left module over that algebra.

Remark 4.2.1.5. Every operation \( \phi \in \text{Mul}_{\text{LM}}(\{X_i\}_{i \in I}, Y) \) determines a linear ordering on the set \( I \). Passage from \( \phi \) to this linear ordering determines a map of colored operads \( \text{LM} \to \text{Ass} \). This map can be understood as follows: for every symmetric monoidal category \( \mathcal{C} \) and every map of colored operads \( F : \text{Ass} \to \mathcal{C} \), the composite map \( \text{LM} \to \text{Ass} \to \mathcal{C} \) corresponds to the pair \((A, M)\), where \( A \) is the associative algebra object of \( \mathcal{C} \) determined by \( F \) and \( M = A \), regarded as a left module over itself.

Notation 4.2.1.6. We let \( \text{LM}^\circ \) denote the category obtained by applying Construction 2.1.1.7 to the colored operad \( \text{LM} \). We can describe this category more concretely as follows (see Remark 4.1.4):

1. The objects of \( \text{LM}^\circ \) are pairs \((\langle n \rangle, S)\), where \( \langle n \rangle \) is an object of \( \text{Fin}_n \) and \( S \) is a subset of \( \langle n \rangle^\circ \).

2. A morphism from \((\langle n \rangle, S)\) to \((\langle n' \rangle, S')\) in \( \text{LM}^\circ \) consists of a morphism \( \alpha : \langle n \rangle \to \langle n' \rangle \) in \( \text{Ass}^\circ \) satisfying the following conditions:
   - (i) The map \( \alpha \) carries \( S \cup \{\ast\} \) into \( S' \cup \{\ast\} \).
   - (ii) If \( s' \in S' \), then \( \alpha^{-1}\{s'\} \) contains exactly one element of \( S \), and that element is maximal with respect to the linear ordering of \( \alpha^{-1}\{s'\} \).

In terms of this description, the object \( a \in \text{LM} \) corresponds to the object \((\langle 1 \rangle, \emptyset) \in \text{LM}^\circ \), while the object \( m \in \text{LM} \) corresponds to \((\langle 1 \rangle, 1^\circ) \).

We now introduce the \( \infty \)-categorical analogue of Definition 4.2.1.1.

Definition 4.2.1.7. We let \( \mathcal{LM}^\circ \) denote the nerve of the category \( \text{LM}^\circ \). We regard \( \mathcal{LM}^\circ \) as an \( \infty \)-operad via the forgetful functor \( \mathcal{LM}^\circ \to N(\text{Fin}_n) \) (see Example 2.1.21).

Remark 4.2.1.8. The underlying \( \infty \)-category \( \mathcal{LM} \) of \( \mathcal{LM}^\circ \) is isomorphic to the discrete simplicial set \( \Delta^0 \coprod \Delta^0 \) with two vertices, corresponding to the objects \( a, m \in \text{LM} \).

Remark 4.2.1.9. The assertion that the forgetful functor \( \mathcal{LM}^\circ \to N(\text{Fin}_n) \) exhibits \( \mathcal{LM}^\circ \) as an \( \infty \)-operad admits the following refinement: the map of colored operads \( \text{LM} \to \text{Ass} \) appearing in Remark 4.2.1.5 induces a fibration of \( \infty \)-operads \( \mathcal{LM}^\circ \to \text{Ass}^\circ \).

Remark 4.2.1.10. The inclusion of colored operads \( \text{Ass} \hookrightarrow \text{LM} \) of Remark 4.2.1.2 determines a map \( \text{Ass}^\circ \hookrightarrow \mathcal{LM}^\circ \), which is an isomorphism from \( \text{Ass}^\circ \) onto the full subcategory of \( \mathcal{LM}^\circ \) spanned by objects of the form \((\langle n \rangle, \emptyset)\). We will generally abuse notation and identify \( \text{Ass}^\circ \) with its image in \( \mathcal{LM}^\circ \).

Notation 4.2.1.11. Let \( \mathcal{C}^\circ \to \mathcal{LM}^\circ \) be a fibration of \( \infty \)-operads. We let \( \mathcal{C}_a^\circ \) denote the fiber product \( \mathcal{C}^\circ \times_{\mathcal{LM}^\circ} \text{Ass}^\circ \) (so that \( \mathcal{C}_a^\circ \) is a planar \( \infty \)-operad, in the sense of Definition 4.1.1.6). We will denote the underlying \( \infty \)-category of \( \mathcal{C}_a^\circ \) by \( \mathcal{C}_a = \mathcal{C}^\circ \times_{\mathcal{LM}^\circ} \{a\} \). We let \( \mathcal{C}_m \) denote the fiber product \( \mathcal{C}^\circ \times_{\mathcal{LM}^\circ} \{m\} \).

Definition 4.2.1.12. Let \( \mathcal{C}^\circ \to \text{Ass}^\circ \) be a planar \( \infty \)-operad and let \( \mathcal{M} \) be an \( \infty \)-category. A weak enrichment of \( \mathcal{M} \) over \( \mathcal{C}^\circ \) is a fibration of \( \infty \)-operads \( q : \mathcal{C}^\circ \to \mathcal{LM}^\circ \) together with isomorphisms \( \mathcal{C}_a^\circ \simeq \mathcal{C}^\circ \) and \( \mathcal{C}_m^\circ \simeq \mathcal{M} \). In this situation, we will say that \( q \) exhibits \( \mathcal{M} \) as weakly enriched over \( \mathcal{C}^\circ \).

Definition 4.2.1.13. Let \( \mathcal{C}^\circ \to \text{Ass}^\circ \) be a planar \( \infty \)-operad, \( \mathcal{M} \) an \( \infty \)-category, and let \( q : \mathcal{C}^\circ \to \mathcal{LM}^\circ \) exhibit \( \mathcal{M} \) as weakly enriched over \( \mathcal{C}^\circ \). We let \( \text{LMod}(\mathcal{M}) \) denote the \( \infty \)-category \( \text{Alg}_{/\mathcal{LM}^\circ}(\mathcal{O}) \). We will refer to \( \text{LMod}(\mathcal{M}) \) as the \( \infty \)-category of left module objects of \( \mathcal{M} \). Composition with the inclusion \( \text{Ass}^\circ \hookrightarrow \mathcal{LM}^\circ \) determines a categorical fibration

\[
\text{LMod}(\mathcal{M}) = \text{Alg}_{/\mathcal{LM}^\circ}(\mathcal{O}) \to \text{Alg}_{/\text{Ass}^\circ}(\mathcal{C}) = \text{Alg}(\mathcal{C}).
\]

If \( A \) is an algebra object of \( \mathcal{C} \), we let \( \text{LMod}_A(\mathcal{M}) \) denote the fiber \( \text{LMod}(\mathcal{M}) \times_{\text{Alg}(\mathcal{C})} \{A\} \); we will refer to \( \text{LMod}_A(\mathcal{M}) \) as the \( \infty \)-category of left \( A \)-module objects of \( \mathcal{M} \).
Remark 4.2.1.14. The notation of Definition 4.2.1.13 is somewhat abusive: the ∞-category LMod(M) depends not only on the ∞-category M, but also on the planar ∞-operad C∞ and on the weak enrichment of M over C∞.

Remark 4.2.1.15. Let M be an ∞-category which is weakly enriched over a planar ∞-operad C∞. We can think of the objects of LMod(M) as given by pairs (A, M), where A is an associative algebra object of C and M is a left A-module in M.

Example 4.2.1.16. Let C∞ → Ass∞ be a planar ∞-operad. Form the fiber product O∞ = C∞ × Ass∞ LM∞ using the fibration of ∞-operads LM∞ → Ass∞ of Remark 4.2.1.9. Then O∞ exhibits the ∞-category C as weakly enriched over C∞. We can therefore consider the ∞-category LMod(C) = AlgLM/M/Ass(C).

Example 4.2.1.17. Let C∞ → Ass∞ be a planar ∞-operad. Composition with the forgetful functor LM∞ → Ass∞ of Remark 4.2.1.9 determines a map s : Alg(C) → LMod(C), which is a section of the projection map LMod(C) → Alg(C). This section can be interpreted as follows: for every algebra object A ∈ Alg(C), the object s(A) ∈ LModLM(A) can be identified with A, regarded as a left module over itself. For this reason, we will often not distinguish in notation between A and s(A).

Example 4.2.1.18. Let C∞ → Ass∞ be a monoidal ∞-category. The objects of LMod(C) = AlgLM/M/Ass(C) are given by functors F : LM∞ → C∞. Then F|Ass∞ is an algebra object of C which we will identify with its underlying object F(a) = A ∈ C. We also have an object F(M) = M ∈ C. As in Remark 4.2.1.3, we see that the unique operation φ ∈ MulLM(A, m) determines a map a : A ⊗ M → M in C, which is well-defined up to homotopy. The requirement that F be defined on the entirety of the ∞-operad LM∞ guarantees that the action map a is compatible with the associative multiplication on A, up to coherent homotopy. In particular, if m : A ⊗ A → A and u : 1 → A denote the multiplication and unit map on A, then the diagrams

\[
\begin{array}{ccc}
A \otimes A \otimes M & \xrightarrow{m \otimes \text{id}} & A \otimes M \\
\downarrow \text{id} \otimes a & & \downarrow a \\
A \otimes M & \xrightarrow{a} & M
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
1 \otimes M & \xrightarrow{u \otimes \text{id}} & A \otimes M \\
\downarrow a & & \downarrow a \\
M & & M
\end{array}
\]

commute up to homotopy.

Definition 4.2.1.19. Let q : C∞ → LM∞ be a fibration of ∞-operads. We will say that q exhibits Cm as left-tensored over Cn if q is a coCartesian fibration of ∞-operads.

Remark 4.2.1.20. Let C∞ → LM∞ be a coCartesian fibration of ∞-operads. Then the induced map Cn → Ass is also a coCartesian fibration of ∞-operads, so that Cn is a monoidal ∞-category.

Remark 4.2.1.21. Let q : C∞ → LM∞ be a coCartesian fibration of ∞-operads. Then q is classified by a map χ : LM∞ → Cat∞ which is an LM-monoid object of Cat∞ (Example 4.2.4.2). We can identify χ with an object of MonLM(Cat∞) ⊆ AlgLM(Cat∞) = LMod(Cat∞) (Proposition 2.4.2.5). More informally: q can be thought of as giving an associative algebra Cn in Cat∞, together with a left module Cm over Cn. In particular, q determines an action map

\[ \otimes : C_n \times C_m \rightarrow C_m \]

which is well-defined up to homotopy (and compatible with the monoidal structure on Cn up to homotopy).

Notation 4.2.1.22. Let q : C∞ → LM∞ be a fibration of ∞-operads, so that q exhibits Cm as weakly enriched over the planar operad C∞. Given an ordered sequence of objects C1, \ldots, Cn ∈ Cn and a pair of objects M, N ∈ Cm, we let MapCm((C1, \ldots, Cn) × M, N) denote the summand of the mapping space MulC((C1, \ldots, Cn, M), \{N\}) corresponding to the linear ordering \{1 < 2 < \cdots < n\} of the set (n).

Remark 4.2.1.23. In the special case n = 0, the mapping space MapCm((C1, \ldots, Cn) × M, N) can be identified with the usual mapping space MapCm(M, N) in the ∞-category Cm.
Example 4.2.1.24. Suppose that $q : \mathcal{C}^\otimes \to \mathcal{LM}^\otimes$ is a coCartesian fibration of $\infty$-operads, so that $q$ determines tensor product functors

$$\otimes : \mathcal{C}_a \times \mathcal{C}_a \to \mathcal{C}_a \quad \otimes : \mathcal{C}_a \times \mathcal{C}_m \to \mathcal{C}_m.$$ 

Unwinding the definitions, we obtain a homotopy equivalence

$$\text{Map}_{\mathcal{C}_m} \{\{C_1, \ldots, C_n\} \otimes M, N\} \simeq \text{Map}_{\mathcal{C}_n} \{C_1 \otimes \cdots \otimes C_n \otimes M, N\},$$

generalizing the homotopy equivalence of Remark 4.2.1.23 to the case $n > 0$.

Our next goal is to give a criterion for testing if a fibration of $\infty$-operads $\mathcal{C}^\otimes \to \mathcal{LM}^\otimes$ is a coCartesian fibration.

Definition 4.2.1.25. Let $q : \mathcal{C}^\otimes \to \mathcal{LM}^\otimes$ be a fibration of $\infty$-operads. We will say that $\mathcal{C}_m$ is pseudo-enriched over $\mathcal{C}_a^\otimes$ if the following conditions are satisfied:

1. The planar $\infty$-operad $\mathcal{C}_a^\otimes$ is a monoidal $\infty$-category.
2. For every sequence of objects $C_1, \ldots, C_n \in \mathcal{C}_a$ and every pair of objects $M, N \in \mathcal{C}_m$, the canonical map

$$\text{Map}_{\mathcal{C}_m} \{\{C_1 \otimes \cdots \otimes C_n\} \otimes M, N\} \to \text{Map}_{\mathcal{C}_n} \{\{C_1, \ldots, C_n\} \otimes M, N\}$$

is a homotopy equivalence.

Proposition 4.2.1.26. Let $q : \mathcal{C}^\otimes \to \mathcal{LM}^\otimes$ be a fibration of $\infty$-operads. Then $q$ is a coCartesian fibration if and only if the following conditions are satisfied:

1. The map $q$ exhibits $\mathcal{C}_m$ as pseudo-enriched over $\mathcal{C}_a^\otimes$.
2. For every object $M \in \mathcal{C}_m$ and every object $C \in \mathcal{C}_a$, there exists a morphism $\phi \in \text{Map}_{\mathcal{C}_n} \{\{C\} \otimes M, M'\}$ with the following universal property: for every pair of objects $C' \in \mathcal{C}_a$, $N \in \mathcal{C}_m$, composition with $\phi$ induces a homotopy equivalence

$$\text{Map}_{\mathcal{C}_m} \{\{C'\} \otimes M', N\} \to \text{Map}_{\mathcal{C}_m} \{\{C', C\} \otimes M, N\}.$$ 

Remark 4.2.1.27. If the hypotheses of Proposition 4.2.1.26 are satisfied, then the object $M'$ appearing in hypothesis (2) can be identified with $C \otimes M$, where $\otimes : \mathcal{C}_a \times \mathcal{C}_m \to \mathcal{C}_m$ is the tensor product functor of Remark 4.2.1.21.

Proof. The necessity of conditions (1) and (2) is obvious. We will prove the sufficiency. Assume that conditions (1) and (2) are satisfied. Fix an object $X \in \mathcal{C}^\otimes$ lying over an object $\langle n \rangle, S \rangle \in \mathcal{LM}^\otimes$, and let $\alpha : \langle n \rangle, S \rangle \to \langle n', S' \rangle$ be a morphism in $\mathcal{LM}^\otimes$; we wish to show that $\alpha$ can be lifted to a $q$-coCartesian morphism $X \to X''$ in $\mathcal{C}^\otimes$. We may assume without loss of generality that $\alpha$ is active. We observe that $\alpha$ admits a canonical factorization

$$\langle n \rangle, S \rangle \xrightarrow{\alpha'} \langle n', S' \rangle \xrightarrow{\alpha''} \langle n'', S'' \rangle$$

with the following properties:

1. The map $\alpha'$ induces a bijection $S \simeq S'$.
2. For each $i \in \langle n'' \rangle^\circ$, the inverse image $\alpha''^{-1} \{i\}$ contains exactly only element of $\langle n' \rangle^\circ - S'$.

According to Proposition T.2.4.1.7, it will suffice to show that $\alpha'$ can be lifted to a $q$-coCartesian morphism $\overline{\alpha} : X \to X'$ and that $\alpha''$ can be lifted to a $q$-coCartesian morphism $\overline{\alpha} : X \to X''$. We first use assumption
(1) to choose a locally \( q \)-coCartesian morphism \( \alpha' : X \to X' \). We claim that \( \alpha' \) is \( q \)-coCartesian. Using Proposition T.2.4.1.43, we are reduced to proving that a product of maps of the form
\[
\text{Map}_e_m\left(\{C_1 \otimes \cdots \otimes C_{k_1}, C_{k_1+1} \otimes \cdots \otimes C_{k_2}, \ldots, C_{k_n-1+1} \otimes \cdots \otimes C_{k_n}\} \otimes M, N\right) \to \text{Map}_e_m\left(\{C_1, \ldots, C_{k_1}\} \otimes M, N\right)
\]
is a homotopy equivalence. This follows from (1), which implies that both sides are homotopy equivalent to \( \text{Map}_e_m\left(\{C_1 \otimes \cdots \otimes C_{k_n}\} \otimes M, N\right) \).

We next use (2) to deduce the existence of a locally \( q \)-coCartesian morphism \( \alpha'' \) lifting \( \alpha'' \). Once again, we prove that \( \alpha'' \) is \( q \)-coCartesian using the criterion of Proposition T.2.4.43. Unwinding the definitions, we must show that if \( \phi \in \text{Map}_e_m\left(\{C\} \otimes M, M'\right) \) is as in (3) and we are given a finite sequence of objects \( C_1, \ldots, C_n \in e_a \), then for each \( N \in e_m \) the induced map
\[
\psi : \text{Map}_e_m\left(\{C_1, \ldots, C_n\} \otimes M', N\right) \to \text{Map}_e_m\left(\{C_1, \ldots, C_n, C\} \otimes M, N\right)
\]
is a homotopy equivalence. This follows from our assumption on \( M' \), since condition (1) allows us to identify \( \psi \) with the homotopy equivalence
\[
\text{Map}_e_m\left(\{C'\} \otimes M', N\right) \to \text{Map}_e_m\left(\{C', C\} \otimes M, N\right) \simeq \text{Map}_e_m\left(\{C' \otimes C\} \otimes M, N\right),
\]
where \( C' = C_1 \otimes \cdots \otimes C_n \).

Motivated by the second hypothesis of Proposition 4.2.1.26, we introduce two variants of Definition 4.2.1.19.

**Definition 4.2.1.28.** Let \( q : \mathcal{C} \to \mathcal{LM}^\otimes \) be a fibration of \( \infty \)-operads which exhibits \( e_m \) as pseudo-enriched over \( e_a^\otimes \).

Let \( M \) and \( N \) be objects of \( \mathcal{M} = e_m \). A morphism object for \( M \) and \( N \) is an object \( \text{Mor}_\mathcal{M}(M, N) \in e_a \) equipped with a map \( \alpha \in \text{Map}_e_m\left(\{\text{Mor}_\mathcal{M}(M, N)\} \otimes M, N\right) \) with the following universal property: for every object \( C \in e_a \), composition with \( \alpha \) induces a homotopy equivalence
\[
\text{Map}_e_m\left(\{C\} \otimes \text{Mor}_\mathcal{M}(M, N)\right) \to \text{Map}_e_m\left(\{C \otimes M\} \otimes N\right).
\]

Let \( N \) be an object of \( e_m \) and \( C \) an object of \( e_a \). An exponential object is an object \( C N \in \mathcal{M} \) together with a map \( \beta \in \text{Map}_e_m\left(\{C\} \otimes C N, N\right) \) with the following universal property: for every pair of objects \( C' \in e_a \) and \( M \in e_m \), composition with \( \beta \) induces a homotopy equivalence \( \text{Map}_e_m\left(\{C'\} \otimes MN, N\right) \to \text{Map}_e_m\left(\{C', C\} \otimes M, N\right) \).

We will say that \( q \) exhibits \( e_m \) as enriched over \( e_a^\otimes \) if, for every pair of objects \( M, N \in e_m \), there exists a morphism object \( \text{Mor}_\mathcal{M}(M, N) \in e_a \). We will say that \( q \) exhibits \( e_m \) as cotensored over \( e_a^\otimes \) if, for every pair of objects \( C \in e_a \), \( N \in e_m \), there exists an exponential object \( C N \in e_m \).

**Remark 4.2.1.29.** In the situation of Definition 4.2.1.28, a morphism object \( \text{Mor}_\mathcal{M}(M, N) \in e_a \) is determined up to canonical equivalence (provided that it exists). Similarly, an exponential object \( C N \) is determined up to equivalence.

**Remark 4.2.1.30.** Suppose that \( q : \mathcal{C} \to \mathcal{LM}^\otimes \) is a coCartesian fibration of \( \infty \)-operads. Then a map \( \beta \in \text{Map}_e_m\left(\{C\} \otimes C N, N\right) \simeq \text{Map}_e_m\left(C \otimes C N, N\right) \) exhibits \( C N \) as an exponential of \( N \) by \( C \) if and only if, for every object \( M \in e_m \), composition with \( \beta \) induces a homotopy equivalence
\[
\text{Map}_e_m\left(M, C N\right) \to \text{Map}_e_m\left(C \otimes M, N\right).
\]

**Remark 4.2.1.31.** Let \( q : \mathcal{C} \to \mathcal{LM}^\otimes \) be a fibration of \( \infty \)-operads which exhibits \( \mathcal{M} = e_m \) as enriched over \( e_a^\otimes \). Then the morphism objects \( \text{Mor}_\mathcal{M}(M, N) \in e_a \) depend functorially on \( M, N \in e_m \). To see this, we observe that we have a trifunctor \( (e_a \times e_m)^{op} \times e_m \to \mathcal{S} \), given informally by the formula \( (C, M, N) \mapsto \text{Map}_e_m\left(\{C\} \otimes M, N\right) \). We may identify this map with a bifunctor \( e : (e_a^{op} \times e_m) \to \text{Fun}(e_a^{op}, \mathcal{S}) \). Since \( e_a \) is enriched over \( e_a \), then the image of \( e \) is contained in the full subcategory \( \text{Fun}(e_a^{op}, \mathcal{S}) \subseteq \text{Fun}(e_a^{op}, \mathcal{S}) \) spanned
by the essential image of the Yoneda embedding \( j : \mathcal{C}_a \to \text{Fun}(\mathcal{C}^{op}_a, S) \). Composing \( e \) with a homotopy inverse to \( j \), we obtain the desired functor \( \text{Mor} : \mathcal{C}^{op}_m \times \mathcal{C}_m \to \mathcal{C}_a \).

Similarly, if \( \mathcal{C}_m \) is cotensored over \( \mathcal{C}_a \), then formation of exponential objects \((C, N) \mapsto C \times N\) can be regarded as a functor \( \mathcal{C}^{op}_m \times \mathcal{C}_m \to \mathcal{C}_m \).

**Example 4.2.1.32.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category, and regard \( \mathcal{C} \) as left-tensored over itself (Example 4.2.1.16). Then \( \mathcal{C} \) is enriched over itself if and only if it is right closed, and cotensored over itself if and only if it is left closed (Definition 4.1.1.17).

The following result provides a large supply of examples of enriched and cotensored \( \infty \)-categories:

**Proposition 4.2.1.33.** Let \( q : \mathcal{C}^{\otimes} \to \mathcal{LM}^{\otimes} \) be a coCartesian fibration of \( \infty \)-operads. Assume that \( \mathcal{C}_m \) and \( \mathcal{C}_a \) are presentable \( \infty \)-categories.

1. If, for every \( C \in \mathcal{C}_a \), the functor \( C \otimes - : \mathcal{C}_m \to \mathcal{C}_m \) preserves small colimits, then \( \mathcal{C}_m \) is cotensored over \( \mathcal{C}_a \).
2. If, for every \( M \in \mathcal{C}_m \), the functor \( - \otimes M : \mathcal{C}_a \to \mathcal{C}_m \) preserves small colimits, then \( \mathcal{C}_m \) is enriched over \( \mathcal{C}_a \).

**Proof.** This follows immediately from the representability criterion of Proposition T.5.5.2.2 (together with Remark 4.2.1.30, in the case of assertion (1)). \( \square \)

**Remark 4.2.1.34.** A much larger class of examples of enriched \( \infty \)-categories can be obtained by combining Proposition 4.2.1.33 with the following observation: if \( \mathcal{C}_m \) is an \( \infty \)-category which is enriched over a monoidal \( \infty \)-category \( \mathcal{C}_a \), then every full subcategory of \( \mathcal{C}_m \) is also enriched over \( \mathcal{C}_a^{\otimes} \).

**Remark 4.2.1.35.** Let \( \mathcal{C}_a^{\otimes} \) be a monoidal \( \infty \)-category. The theory of \( \mathcal{C}_a \)-enriched \( \infty \)-categories is important for many applications of higher category theory. For example, it can be used as the basis for an inductive definition of the notion of \((\infty, n)\)-category for all integers \( n \geq 0 \): an \((\infty, n)\)-category is an \( \infty \)-category which is enriched over \( \text{Cat}(\infty, n-1) \), where \( \text{Cat}(\infty, n-1) \) is the \( \infty \)-category of \((\infty, n-1)\)-categories (endowed with the Cartesian symmetric monoidal structure).

**Variant 4.2.1.36.** By slightly modifying the definitions presented in this section, one can develop an entirely parallel theory of right modules in the \( \infty \)-categorical setting. We define a category \( \mathcal{RM}^{\otimes} \) as follows (compare with Notation 4.2.1.6):

1. The objects of \( \mathcal{RM}^{\otimes} \) are pairs \((\langle n \rangle, S)\), where \( \langle n \rangle \) is an object of \( \mathcal{F}in \) and \( S \) is a subset of \( \langle n \rangle^{\otimes} \).
2. A morphism from \((\langle n \rangle, S)\) to \((\langle n' \rangle, S')\) in \( \mathcal{RM} \) consists of a morphism \( \alpha : \langle n \rangle \to \langle n' \rangle \) in \( \text{Ass}^{\otimes} \) satisfying the following conditions:
   (i) The map \( \alpha \) carries \( S \cup \{\ast\} \) into \( S' \cup \{\ast\} \).
   (ii) If \( m' \in S' \), then \( \alpha^{-1}\{s'\} \) contains exactly one element of \( S \), and that element is minimal with respect to the linear ordering of \( \alpha^{-1}\{s'\} \).

We let \( \mathcal{RM}^{\otimes} \) denote the \( \infty \)-operad \( \mathcal{N}(\mathcal{RM}^{\otimes}) \). We let \( \mathcal{RM} \) denote the underlying \( \infty \)-category of \( \mathcal{RM}^{\otimes} \), which is isomorphic to the discrete simplicial set \( \{a, m\} \). Given a fibration of \( \infty \)-operads \( \mathcal{C}^{\otimes} \to \mathcal{RM}^{\otimes} \), we let \( \text{RMod}(\mathcal{C}_m) \) denote the \( \infty \)-category \( \text{Alg} \text{Mod}(\mathcal{C}_m) \); we will refer to \( \text{RMod}(\mathcal{C}_m) \) as the \( \infty \)-category of right module objects of \( \mathcal{C}_m \). There is an evident forgetful functor \( \text{RMod}(\mathcal{C}_m) \to \text{Alg}(\mathcal{C}_a) \). For every algebra object \( A \in \mathcal{C}_a \), we let \( \text{RMod}_A(\mathcal{C}_m) \) denote the fiber \( \text{RMod}(\mathcal{C}_m) \times_{\text{Alg}(\mathcal{C}_a)} \{A\} \); we refer to \( \text{RMod}_A(\mathcal{C}_m) \) as the \( \infty \)-category of right \( A \)-module objects of \( \mathcal{C}_m \). All of our discussion concerning left modules can be adapted to the case of right modules without any essential changes.

**Remark 4.2.1.37.** If \( \mathcal{O}^{\otimes} \) is a planar \( \infty \)-operad, then the theory of left modules in \( \mathcal{O}^{\otimes} \) is equivalent to the theory of right \( \mathcal{O}^{\otimes}_{\text{rev}} \) modules, where \( \mathcal{O}^{\otimes}_{\text{rev}} \) is the reverse of \( \mathcal{O}^{\otimes} \); see Remark 4.1.1.8.
4.2.2 Simplicial Models for Algebras and Modules

The $\infty$-operad $\mathcal{LM}^{\otimes}$ of Definition 4.2.1.7 gives rise to a good theory of left modules over associative algebras in the $\infty$-categorical setting. However, for many purposes it is inconvenient to work with the entire simplicial set $\mathcal{LM}^{\otimes}$. Our goal in this section is to describe an alternative approach to the theory of left modules, which based on the ideas introduced in §4.1.2. In §4.2.3, we will apply these ideas to the study of limits and colimits in $\infty$-categories of left modules.

We begin by studying left modules in the category of sets. Let $M$ be a monoid with multiplication map $m : M \times M \to M$ and unit element 1, and let $X$ be a set equipped with a left action of $M$: that is, there is a map of sets $M \times X \to X$ such that the diagrams

$$
\begin{align*}
M \times M \times X \xrightarrow{m \otimes \text{id}} M \otimes X & \quad \xrightarrow{\text{id} \otimes a} M \otimes X \\
M \otimes X & \xrightarrow{a} X
\end{align*}
$$

commute. As explained in Example 4.1.2.1, we can associate to the monoid $M$ a category $\mathcal{D}_M$ with a single object $E$, such that $\text{Hom}_{\mathcal{D}_M}(E,E) = M$ and composition of morphisms in $\mathcal{D}_M$ is given by the multiplication $m$. Unwinding the definitions, we see that giving a left action of $M$ on a set $X$ is equivalent to giving a functor $F : \mathcal{D}_M \to \text{Set}$ such that $F(E) = X$: the action of $M$ on $X$ is then encoded by the induced map $M = \text{Hom}_{\mathcal{D}_M}(E,E) \to \text{Hom}_{\text{Set}}(X,X)$. Applying the Grothendieck construction to the functor $F$ (see §T.2.1.1), we can obtain a new category $\mathcal{D}_M$, whose objects are pairs $(e,x)$ where $e$ is an object of $\mathcal{D}_M$ (so that $e = E$, since $\mathcal{D}_M$ has a unique object) and $x$ is an element of $F(e) = F(E) = X$. Finally, we can take the nerve of the category $\mathcal{D}_M$ to obtain a simplicial set, which we will denote by $B_X M$. The forgetful functor $\mathcal{D}_M \to \mathcal{D}_M$ induces a map of simplicial sets $B_X M \to BM$, where $BM$ is the simplicial set described in Example 4.1.2.1.

**Remark 4.2.2.1.** Unwinding the definitions, we can describe the simplicial set $B_X M$ concretely as follows. The collection of $n$-simplices $\text{Hom}_{\text{Set}_\Delta}(\Delta^n, B_X M)$ is isomorphic to $M^n \times X$. Under these isomorphisms, the face and degeneracy maps are given by the formulae

$$
d_i(m_1, \ldots, m_n, x) = \begin{cases} 
(m_2, \ldots, m_n, x) & \text{if } i = 0 \\
(m_1, \ldots, m_i m_{i+1}, m_{i+2}, \ldots, m_n, x) & \text{if } 0 < i < n \\
(m_1, \ldots, m_{n-1}, m_n x) & \text{if } i = n.
\end{cases}
$$

$$
s_i(m_1, \ldots, m_n, x) = (m_1, \ldots, m_i, 1, m_{i+1}, \ldots, m_n, x).
$$

Each step in the construction of $B_X M$ is reversible: the category $\mathcal{D}_M$ can be recovered as the homotopy category of $B_X M \simeq N(\mathcal{D}_M)$, the functor $F : \mathcal{D}_M \to \text{Set}$ can be recovered from the forgetful functor $\mathcal{D}_M \to \mathcal{D}_M$, and $F$ encodes the left action of $M$ on $X$. We can summarize the situation as follows: the construction $X \mapsto B_X M$ determines a fully faithful embedding from the category of left $M$-modules to the category of simplicial sets mapping to $BM$. Moreover, it is easy to describe the essential image of this functor: given a map of simplicial sets $K \to BM$, there exists a left action of $M$ on a set $X$ and an isomorphism $K \simeq B_X M$ if and only if, for every integer $n \geq 0$, the inclusion $\{n\} \to [n]$ induces a bijection

$$
\text{Hom}_{\text{Set}_\Delta}(\Delta^n, K) \to \text{Hom}_{\text{Set}_\Delta}(\Delta^n, BM) \times \text{Hom}_{\text{Set}_\Delta}(\Delta^n, K);
$$

in this case, $X$ can be recovered as the set of vertices of $K$.

Motivated by the above discussion, we introduce the definition of a left action of a monoid in an arbitrary $\infty$-category.

**Definition 4.2.2.2.** Let $\mathcal{C}$ be an $\infty$-category. A left action object of $\mathcal{C}$ is a natural transformation $\alpha : M' \to M$ in $\text{Fun}(N(\Delta)^{op}, \mathcal{C})$ with the following properties:
4.2. LEFT AND RIGHT MODULES

(i) The simplicial object $M \in \text{Fun}(\Delta^{op}, \mathcal{C})$ is a monoid object of $\mathcal{C}$, in the sense of Definition 4.1.2.2.

(ii) For each integer $n \geq 0$, the map $M'([n]) \to M([n])$ and the map $M'([n]) \to M'([n+1])$ exhibit $M'([n])$ as a product of $M'([0])$ with $M([n])$ in $\mathcal{C}$.

We let $\text{LMon}(\mathcal{C})$ denote the full subcategory of $\text{Fun}(\Delta^{op} \times \Delta^1, \mathcal{C})$ spanned by the left action objects of $\mathcal{C}$.

**Remark 4.2.2.3.** Let $\alpha : M' \to M$ be a left action object of an $\infty$-category $\mathcal{C}$. Following the abuse of Remark 4.1.2.3, we will sometimes say that $M([1]) \in \mathcal{C}$ is the underlying monoid object of $\alpha$ and that $M'([0]) \in \mathcal{C}$ is equipped with a left action of $M([1])$. This left action is encoded by the map

$$M([1]) \times M'([0]) = M([1]) \times M'([1]) \to M'([1]) \to M'([0]) = M'([0]).$$

**Example 4.2.2.4.** Let $T : \Delta^{op} \to \Delta^{op}$ be the translation functor given by $[n] \mapsto [n+1]$. The inclusion maps $[n] \to [n+1]$ determine a natural transformation $T \to \text{id}$. This natural transformation gives a map $\text{Fun}(\Delta^{op}, \mathcal{C}) \to \text{Fun}(\Delta^{op} \times \Delta^1, \mathcal{C})$, which carries $\text{Mon}(\mathcal{C})$ into $\text{LMon}(\mathcal{C})$. We can summarize the situation informally as follows: if $M$ is any monoid object of $\mathcal{C}$, then there is a natural left action of $M$ on itself.

**Notation 4.2.2.5.** Let $\mathcal{C}$ be an $\infty$-category. By construction, there is a forgetful functor $\text{LMon}(\mathcal{C}) \to \text{Mon}(\mathcal{C})$, which carries a natural transformation $\alpha : M' \to M$ to the subset $\text{Cut}(\alpha) \subseteq \text{LMon}(\mathcal{C})$.

Our first goal in this section is to prove an analogue of Proposition 4.1.2.6, which compares left action objects of $\mathcal{C}$ with $\mathcal{L}M^{\circ}$-monoid objects of $\mathcal{C}$ (Proposition 4.2.2.9 below). To formulate this result, we need a slightly more elaborate version of Construction 4.1.2.5.

**Construction 4.2.2.6.** For every finite linearly ordered set $[n]$, let $\text{LCut}_0([n])$ denote the collection of all downward-closed subsets $S \subseteq [n]$. There is a canonical bijection $(n+1) \simeq \text{LCut}_0([n])$, which carries the base point $* \in (n+1)$ to the empty subset $\emptyset \subseteq [n]$ and an integer $i \in (n+1)^\circ$ to the subset $\{j \in [n] : j < i\}$. In what follows, we will identify $\text{LCut}_0([n])$ with $(n+1)$ under this bijection.

The construction $[n] \mapsto (\text{LCut}_0([n]), \{[n]\}) \simeq ([n], \{n+1\})$ determines a functor $\text{LCut} : \Delta^{op} \to \text{LM}^{\circ}$. Namely, if we are given a map $\alpha : [m] \to [n]$ in $\Delta$, there is an induced map $\alpha' : \text{LCut}_0([m]) \to \text{LCut}_0([n])$, given by the formula $\alpha'(S) = \alpha^{-1}S$. The map $\alpha'$ preserves base points (since the inverse image of an empty set is empty). Moreover, for each $0 \neq S \in \text{LCut}_0([m])$, the inverse image $\alpha'^{-1}(S) \subseteq \text{LCut}_0([n])$ is linearly ordered by inclusion (under the bijection $\text{LCut}_0([n]) \simeq (n+1)$, this linear ordering is induced by the usual ordering of $(n+1)^\circ = \{1 < \cdots < n+1\}$).

More explicitly, the functor $\text{LCut}$ can be described as follows:

1. For each $n \geq 0$, we have $\text{Cut}([n]) = ([n], \{n+1\})$.

2. Given a morphism $\alpha : [n] \to [m]$ in $\Delta$, the associated morphism $\text{Cut}(\alpha) : (m+1) \to (n+1)$ is given by the formula

$$\text{Cut}(\alpha)(i) = \begin{cases} j & \text{if } (\exists j)[1 \leq j \leq n \land \alpha(j-1) < i \leq \alpha(j)] \\ n+1 & \text{if } \alpha(n) < i \\ * & \text{otherwise.} \end{cases}$$

for $i \in (m+1)^\circ$, where we endow each $\text{Cut}(\alpha)^{-1}\{j\}$ with the linear ordering induced by its inclusion into $(n)^\circ$.

Passing to nerves, the functor $\text{LCut}$ determines a map of simplicial sets $\Delta^{op} \to \text{LM}^{\circ}$, which we will also denote by $\text{LCut}$. 
Remark 4.2.2.7. The functor $LCut_0$ of Construction 4.2.2.6 is almost identical to the functor Cut of Construction 4.1.2.5. Both constructions assign to an object $[n] \in \Delta$ a set which parametrizes decompositions $[n] \simeq S \coprod T$, where $S$ is a downward closed subset of $[n]$ and $T$ its complement. The only difference is that the decompositions $[n] \simeq [n] \coprod \emptyset$ and $[n] \simeq \emptyset \coprod [n]$ are considered to represent the same element of $Cut([n]) \simeq \langle n \rangle$ (namely, the base point of $\langle n \rangle$), but different elements of $LCut_0([n]) \simeq \langle n+1 \rangle$ (the decomposition $[n] \simeq [n] \coprod \emptyset$ corresponds to the element $n+1 \in \langle n+1 \rangle$, while $[n] \simeq \emptyset \coprod [n]$ corresponds to the base point $* \in \langle n+1 \rangle$).

Remark 4.2.2.8. Let us identify $Ass^\otimes$ with the full subcategory of $LM^\otimes$ spanned by objects of the form $\langle (n), T \rangle$ where $T$ is empty, as in Remark 4.2.1.10. We can therefore think of the functor Cut of Construction 4.1.2.5 as a map from $N(\Delta)^{op}$ into $LM^\otimes$. For each $[n] \in \Delta$, there is an evident map of sets $\theta : LCut_0([n]) \to LCut([n])$, which carries a subset $S \subseteq [n]$ to the equivalence relation $\sim$, where $i \sim j$ if either $i, j \in S$ or $i, j \notin S$. More concretely, $\theta : \langle n+1 \rangle \to \langle n \rangle$ is given by the formula

$$\theta(k) = \begin{cases} * & \text{if } k = n+1 \\ k & \text{otherwise.} \end{cases}$$

This construction determines a morphism $\gamma : LCut \to Cut$ in the $\infty$-category $Fun(N(\Delta)^{op}, LM^\otimes)$. When convenient, we will identify $\gamma$ with a map $N(\Delta)^{op} \times \Delta^1 \to LM^\otimes$. It is not difficult to see that this map is an approximation to the $\infty$-operad $LM^\otimes$ (see the proof of Proposition 4.1.2.10).

Combining Remark 4.2.2.8 with Proposition 4.1.2.11, we obtain the following result:

**Proposition 4.2.2.9.** Let $\mathcal{C}$ be an $\infty$-category finite admits finite products. Composition with the functor $\gamma : N(\Delta)^{op} \times \Delta^1 \to LM^\otimes$ induces an equivalence of $\infty$-categories

$$Mon_{LM}(\mathcal{C}) \to LMon(\mathcal{C}).$$

Combining Proposition 4.2.2.9 with Proposition 2.4.2.5, we obtain an efficient description of left module objects in an arbitrary $\infty$-category $\mathcal{C}$ which is equipped with a Cartesian symmetric monoidal structure. Our goal for the remainder of this section is to obtain a generalization of this description which applies to a general fibration of generalized $\infty$-operads $O^\otimes \to LM^\otimes$. First, we need to introduce the analogue of Definition 4.2.2.2.

**Definition 4.2.2.10.** Let $q : O^\otimes \to LM^\otimes$ be a fibration of $\infty$-operads, so that $q$ exhibits the $\infty$-category $M = 0_m$ as weakly enriched over the planar $\infty$-operad $O^\otimes_a$. Let $\gamma : N(\Delta)^{op} \times \Delta^1 \to LM^\otimes$ be as in Remark 4.2.2.8. We let $\Delta LM(\mathcal{M})$ denote the full subcategory of $Fun_{LM^\otimes}(N(\Delta)^{op} \times \Delta^1, O^\otimes)$ spanned by those maps $f : N(\Delta)^{op} \times \Delta^1 \to O^\otimes$ which satisfy the following conditions:

1. The restriction $f|\{N(\Delta)^{op} \times \{1\}\}$ belongs to $\Delta Alg(\mathcal{C}) \subseteq Fun_{Ass^\otimes}(N(\Delta)^{op}, \mathcal{C}^\otimes)$ (see Definition 4.1.2.14).
2. If $\alpha : [m] \to [n]$ is an inert morphism in $\Delta$ such that $\alpha(m) = n$, then the induced map $f([n], 0) \to f([m], 0)$ is an inert morphism in $O^\otimes$.
3. For each $[n] \in \Delta$, the induced map $f([n], 0) \to f([n], 1)$ is an inert morphism in $O^\otimes$.

Combining Remark 4.2.2.8 with Theorem 2.3.3.23, we obtain the following counterpart of Proposition 4.2.2.9:

**Proposition 4.2.2.11.** Let $p : O^\otimes \to LM^\otimes$ be a fibration of $\infty$-operads and let $M = 0_m$. Then composition with the functor $\gamma : N(\Delta)^{op} \times \Delta^1 \to LM^\otimes$ of Remark 4.2.2.8 induces an equivalence of $\infty$-categories

$$\Delta Alg_{LM}(O) \to \Delta LM(\mathcal{M}).$$

Let $M$ be as in Remark 4.2.2.25, so that the functor $\gamma$ of Remark 4.2.2.8 defines a map of $\infty$-preoperads $\pi : (N(\Delta)^{op} \times \Delta^1, M) \to LM^{\otimes, \Delta}$. Note that Proposition 4.2.2.11 is equivalent to the statement that $\pi$ is weak equivalence with respect to the $\infty$-operadic model structure of Proposition 2.1.4.6. For later use, we establish a stronger version of Proposition 4.2.2.11:
Proposition 4.2.2.12. Let $(N(\Delta)^{op} \times \Delta^1, M)$ be the marked simplicial set described in Remark 4.2.2.25. Then the map $\tau: (N(\Delta)^{op} \times \Delta^1, M) \to \mathcal{LM}^{\otimes, \ast}$ is a weak equivalence with respect to the generalized $\infty$-operad model structure described in Remark 2.3.2.4.

The proof is a mild variation on the proof of Theorem 2.3.3.23, and will be given at the end of this section.

Remark 4.2.2.13. Let $p: \mathcal{O}^{\otimes} \to \mathcal{LM}^{\otimes}$ be a fibration of $\infty$-operads, which exhibits the $\infty$-category $\mathcal{M} = \mathcal{O}_m$ as weakly enriched over the planar $\infty$-operad $\mathcal{O}_{\ast}$. We will generally abuse terminology by referring to $\mathcal{LM}(\mathcal{M})$ as the $\infty$-category of left module objects of $\mathcal{M}$. Though this terminology is in conflict with that of Definition 4.2.1.13, our abuse is justified by Proposition 4.2.2.11.

Notation 4.2.2.14. Let $\mathcal{M}$ be an $\infty$-category which is weakly enriched over a planar $\infty$-operad $\mathcal{E}^{\otimes}$. By construction, the inclusion $N(\Delta)^{op} \times \{1\} \hookrightarrow N(\Delta)^{op} \times \Delta^1$ induces a forgetful functor $\mathcal{LM}(\mathcal{M}) \to \mathcal{Alg}(\mathcal{E})$. If $A \in \mathcal{Alg}(\mathcal{E})$, we let $\mathcal{LM}(\mathcal{M})$ denote the fiber $\mathcal{LM}(\mathcal{M}) \times_{\mathcal{Alg}(\mathcal{E})} \{A\}$. Following the abuse of Remark 4.2.2.13, we will refer to $\mathcal{LM}(\mathcal{M})$ as the $\infty$-category of left $A$-module objects of $\mathcal{M}$.

Let $\mathcal{M}$ be an $\infty$-category which is weakly enriched over a planar $\infty$-operad $\mathcal{E}^{\otimes}$. The functor $\mathcal{LM}(\mathcal{M}) \to \mathcal{LM}(\mathcal{M})$ fits into a commutative diagram

$$
\begin{align*}
\mathcal{LM}(\mathcal{M}) & \longrightarrow \mathcal{LM}(\mathcal{M}) \\
\downarrow & \downarrow \\
\mathcal{Alg}(\mathcal{E}) & \longrightarrow \mathcal{LM}(\mathcal{M}).
\end{align*}
$$

Combining Propositions 4.2.2.11 and 4.1.2.15, we obtain:

Corollary 4.2.2.15. Let $\mathcal{M}$ be an $\infty$-category which is weakly enriched over a planar $\infty$-operad $\mathcal{E}^{\otimes}$. Let $A \in \mathcal{Alg}(\mathcal{E})$ be an algebra object of $\mathcal{E}$ and let $A'$ be its image in $\mathcal{LM}$. Then the functor $\mathcal{L}(\mathcal{M})$ induces an equivalence of $\infty$-categories $\mathcal{LM}(\mathcal{M}) \to \mathcal{LM}(\mathcal{M})$.

The remainder of this section is devoted to introducing some notation which will facilitate the application of Proposition 4.2.2.11.

Notation 4.2.2.16. Let $q: \mathcal{O}^{\otimes} \to \mathcal{LM}^{\otimes}$ be a fibration of $\infty$-operads, so that $q$ exhibits the $\infty$-category $\mathcal{M} = \mathcal{O}_m$ as weakly enriched over the planar operad $\mathcal{E}^{\otimes} = \mathcal{O}_m$. We let $\mathcal{Cut}: N(\Delta)^{op} \to \mathcal{Ass}^{\otimes}$ be the functor of Construction 4.1.2.5, and $\mathcal{E}^{\otimes}$ denote the fiber product $\mathcal{E}^{\otimes} \times_{\mathcal{Ass}^{\otimes}} N(\Delta)^{op}$.

We define a simplicial set $\overline{M}^{\otimes}$ together with a map $\overline{M}^{\otimes} \to N(\Delta)^{op}$ so that the following universal property is satisfied: for every simplicial set $K$ equipped with a map $K \to N(\Delta)^{op}$, there is a canonical bijection

$$
\text{Hom}_{(\mathcal{Set}_\Delta)/N(\Delta)^{op}}(K, \overline{M}^{\otimes}) \simeq \text{Hom}_{(\mathcal{Set}_\Delta)/\mathcal{LM}(\Delta)}(K \times \Delta^1, \mathcal{O}^{\otimes}).
$$

Here we regard $K \times \Delta^1$ as an object of $(\mathcal{Set}_\Delta)/\mathcal{LM}$ via the map

$$
K \times \Delta^1 \to N(\Delta)^{op} \times \Delta^1 \to \mathcal{LM},
$$

where $\gamma$ is the functor described in Remark 4.2.2.8.

Unwinding the definitions, we see that a vertex of $\overline{M}^{\otimes}$ lying over an object $[n] \in \Delta^{op}$ corresponds to a morphism $\alpha$ in $\mathcal{O}^{\otimes}$ such that $q(\alpha)$ is the map $\theta: ((n + 1), \{n + 1\}) \to (\{n\}, \emptyset)$ in $\mathcal{LM}^{\otimes}$ which appears in Remark 4.2.2.8. We let $M^{\otimes}$ denote the full simplicial subset of $\overline{M}^{\otimes}$ spanned by those vertices for which $\alpha$ is inert.
**Remark 4.2.2.17.** Let \( q : \mathcal{O}^\otimes \to \mathcal{L}\mathcal{M}^\otimes \) be a fibration of \( \infty \)-operads, so that \( q \) exhibits the \( \infty \)-category \( \mathcal{M} = \mathcal{O}_m \) as weakly enriched over the planar operad \( \mathcal{C}^\otimes = \mathcal{O}_n^\otimes \). Using Proposition T.4.3.2.15, we deduce that composition with the inclusion \( \{0\} \hookrightarrow \Delta^1 \) induces a trivial Kan fibration \( \mathcal{M}^\otimes \to \mathcal{O}^\otimes \times_{\mathcal{L}\mathcal{M}^\otimes} N(\Delta)^{op} \), where \( N(\Delta)^{op} \) maps to \( \mathcal{L}\mathcal{M}^\otimes \) via the functor \( \text{LCut} \) of Construction 4.2.2.6. In particular, the fiber of \( \mathcal{M}^\otimes \) over an object \([n] \in \Delta^{op}\) is canonically equivalent to \( \mathcal{M} \times \mathcal{C}^n \).

**Remark 4.2.2.18.** Let \( \mathcal{M} \) be an \( \infty \)-category which is weakly enriched over a planar \( \infty \)-operad \( \mathcal{C}^\otimes \). We have categorical fibrations

\[
\mathcal{M}^\otimes \xrightarrow{\mathcal{F}} \mathcal{C}^\otimes \xrightarrow{p} N(\Delta)^{op};
\]

in particular, both \( \mathcal{M}^\otimes \) and \( \mathcal{C}^\otimes \) are \( \infty \)-categories.

Let us identify \( \Delta \text{Alg}(\mathcal{C}) \) with a full subcategory of the \( \infty \)-category \( \text{Fun}_{N(\Delta)^{op}}(N(\Delta)^{op}, \mathcal{C}^\otimes) \) of sections of \( p \), and \( \Delta \text{LM}_{\mathcal{M}} \) with a full subcategory of the \( \infty \)-category \( \text{Fun}_{N(\Delta)^{op}}(N(\Delta)^{op}, \mathcal{M}^\otimes) \) of sections of \( p \circ q \).

If \( A \in \Delta \text{Alg}(\mathcal{C}) \), then \( A \) determines a functor \( N(\Delta)^{op} \times \mathcal{C}^\otimes \), and we can identify \( \Delta \text{LM}_{\mathcal{M}} \) with a full subcategory of the \( \infty \)-category \( \text{Fun}_{N(\Delta)^{op}}(N(\Delta)^{op}, \mathcal{M}^\otimes \times_{\mathcal{C}^\otimes} N(\Delta)^{op}) \).

Note that an object \( F \in \text{Fun}_{N(\Delta)^{op}}(N(\Delta)^{op}, \mathcal{M}^\otimes) \) belongs to \( \Delta \text{LM}_{\mathcal{M}} \) if and only if the following conditions are satisfied:

1. The image of \( F \in \text{Fun}_{N(\Delta)^{op}}(N(\Delta)^{op}, \mathcal{C}^\otimes) \) belongs to \( \Delta \text{Alg}(\mathcal{C}) \).
2. If \( \alpha : [m] \to [n] \) is an inert morphism in \( \Delta \) such that \( \alpha(m) = n \), then the induced map \( f([m]) \to f([n]) \) is a \((p \circ q)\)-coCartesian morphism in \( \mathcal{M}^\otimes \).

We now record a few simple properties of the forgetful map \( \mathcal{M}^\otimes \to \mathcal{C}^\otimes \) which will be useful later.

**Lemma 4.2.2.19.** Suppose we are given a coCartesian fibration of \( \infty \)-operads \( \mathcal{O}^\otimes \to \mathcal{L}\mathcal{M}^\otimes \), which exhibits \( \mathcal{M} = \mathcal{O}_m \) as left-tensored over the monoidal \( \infty \)-category \( \mathcal{C}^\otimes = \mathcal{O}_n^\otimes \). Then the associated functor \( \mathcal{M}^\otimes \to \mathcal{C}^\otimes \) is a locally coCartesian fibration.

**Proof.** For each \( n \geq 0 \), the map \( p_{[n]} : \mathcal{M}_{[n]}^\otimes \to \mathcal{C}^\otimes_{[n]} \) is equivalent to the projection \( \mathcal{C}^\otimes_{[n]} \times \mathcal{M} \to \mathcal{C}^\otimes_{[n]} \) (see Remark 4.2.2.17). The desired result now follows from Proposition T.2.4.2.11.

**Remark 4.2.2.20.** In the situation of Lemma 4.2.2.19, suppose we are given a morphism \( \pi : C \to D \) in \( \mathcal{C}^\otimes \), covering a map \( \alpha : [m] \to [n] \) in \( \Delta \). We can identify \( C \) with an \( n \)-tuple of objects \( (C_1, \ldots, C_n) \in \mathcal{C}^n \), and \( \pi \) with a collection of morphisms \( C_{\alpha(i)-1+1} \otimes \ldots \otimes C_{\alpha(i)} \to D_i \). The fibers of the map \( p : \mathcal{M}^\otimes \to \mathcal{C}^\otimes \) over the objects \( C \) and \( D \) are both canonically equivalent to \( \mathcal{M} \), and the induced functor \( \pi : \mathcal{M} \to \mathcal{M} \) is given (up to equivalence) by the formula \( F \mapsto C_{\alpha(m)+1} \otimes \ldots \otimes C_n \otimes M \).

**Remark 4.2.2.21.** Let \( p : \mathcal{M}^\otimes \to \mathcal{C}^\otimes \) be as in Lemma 4.2.2.19, and suppose given a commutative triangle

\[
\begin{array}{ccc}
M' & \xrightarrow{f} & M'' \\
\downarrow & & \downarrow \\
M & \xrightarrow{h} & M''
\end{array}
\]

in \( \mathcal{M}^\otimes \), covering a triangle

\[
\begin{array}{ccc}
[n] & \xrightarrow{\alpha} & [k] \\
\downarrow & \downarrow & \downarrow \\
\{i \in [m] : \beta(i) < i\} & \simeq & \{j \in [n] : \gamma(j) < j \leq \alpha(m)\}
\end{array}
\]

in the category \( \Delta \). Suppose furthermore that \( f \) and \( g \) are locally \( p \)-coCartesian, and that \( \alpha \) induces a bijection

\[
\{i \in [m] : \beta(i) < i\} \simeq \{j \in [n] : \gamma(j) < j \leq \alpha(m)\}
\]

(so that, in particular, \( \beta(i) < i \leq m \) implies \( \gamma(k) < \alpha(i) \)). Then the description given in Remark 4.2.2.20 implies that \( h \) is also locally \( p \)-coCartesian.
4.2. LEFT AND RIGHT MODULES

Remark 4.2.2.22. Let \( p : M^\otimes \to C^\otimes \) be as in Lemma 4.2.2.19, and let \( \pi \) be a morphism in \( M^\otimes \) which covers a map \( \alpha : [m] \to [n] \) in \( \Delta \). Then:

1. Suppose that \( \alpha(m) = n \) and \( \pi \) is locally \( p \)-Cartesian. Then \( \pi \) is \( p \)-Cartesian.

2. Suppose that \( m \leq n \), that \( \alpha : [m] \to [n] \) is the canonical inclusion, and that \( \pi \) is locally \( p \)-coCartesian. Then \( \pi \) is \( p \)-coCartesian.

Assertion (1) follows from Remark 4.2.2.21 and Lemma T.5.2.2.3, while (2) follows from Remark 4.2.2.21 and Lemma T.2.4.2.7.

Proposition 4.2.2.23. Suppose we are given a coCartesian fibration of \( \infty \)-operads \( \mathcal{O}^\otimes \to \mathcal{L}M^\otimes \), which exhibits \( M = \mathcal{O}_m \) as left-tensored over the monoidal \( \infty \)-category \( \mathcal{C}^\otimes = \mathcal{O}_a^\otimes \). Let \( \pi \) be a morphism in \( M^\otimes \) which covers a map \( \alpha : [m] \to [n] \) in \( \Delta \). Then:

1. Suppose that \( \alpha(m) = n \) and \( \pi \) is locally \( p \)-Cartesian. Then \( \pi \) is \( p \)-Cartesian.

2. Suppose that \( m \leq n \), that \( \alpha : [m] \to [n] \) is the canonical inclusion, and that \( \pi \) is locally \( p \)-coCartesian. Then \( \pi \) is \( p \)-coCartesian.

Proof. Assertion (1) follows from Remark 4.2.2.21 and Lemma T.5.2.2.3, while (2) follows from Remark 4.2.2.21 and Lemma T.2.4.2.7. \( \square \)

Remark 4.2.2.24. Let \( q : \mathcal{O}^\otimes \to \mathcal{L}M^\otimes \) be a coCartesian fibration of \( \infty \)-operads. Then \( q \) is classified by a functor \( \mathcal{L}M^\otimes \to \mathcal{C}at_\infty \) which is an \( \mathcal{L}M \)-monoid object of \( \mathcal{C}at_\infty \) (Example 2.4.2.4). According to Proposition 4.2.2.9, this \( \mathcal{L}M \)-monoid object is determined up to equivalence by the induced map \( N(\Delta)^{op} \times \Delta^1 \to \mathcal{C}at_\infty \), which we can view as a morphism in \( \text{Fun}(N(\Delta)^{op}, \mathcal{C}at_\infty) \). This morphism classifies the map \( M^\otimes \to \mathcal{C}^\otimes \) of Notation 4.2.2.16. In other words, the data contained in the coCartesian fibration of \( \infty \)-operads \( q : \mathcal{O}^\otimes \to \mathcal{L}M^\otimes \) is equivalent to the data contained in the diagram

\[
M^\otimes \to \mathcal{C}^\otimes \to N(\Delta)^{op},
\]
either can be reconstructed from the other, up to equivalence.

We now turn to the proof of Proposition 4.2.12.

Remark 4.2.2.25. Let \( \gamma : N(\Delta)^{op} \times \Delta^1 \to \mathcal{L}M^\otimes \) be as in Remark 4.2.2.8, and let \( M \) denote the collection of all morphisms \( f \) in \( N(\Delta)^{op} \times \Delta^1 \) such that \( \gamma(f) \) is an inert morphism in \( \mathcal{L}M^\otimes \). We note that if \( q : \mathcal{O}^\otimes \to \mathcal{L}M^\otimes \) is a fibration of \( \infty \)-operads, then a functor \( F \in \text{Fun}_{LMod}(\mathcal{E}_m) \) belongs to \( ^1\text{LMod}(\mathcal{E}_m) \) if and only if \( F \) carries each morphism in \( M \) to an inert morphism in \( \mathcal{C}^\otimes \). The “if” direction is obvious. For the converse, we note that \( F \in \text{LMod}(\mathcal{E}_m) \) and let \( \alpha : ([m], i) \to ([n], j) \) be a morphism in \( N(\Delta)^{op} \times \Delta^1 \) be such that \( \gamma(\alpha) \) is inert. If \( i = j \), then it follows immediately from the definition that \( F(\alpha) \) is inert. If \( i \neq j \), then \( \alpha \) factors as a composition

\[
([m], 0) \xrightarrow{\alpha'} ([n], 0) \xrightarrow{\alpha''} ([n], 1),
\]
where \( F(\alpha') \) and \( F(\alpha'') \) are inert, so that \( F(\alpha) \) is also inert.

Proof of Proposition 4.2.2.12. Let \( q : \mathcal{O}^\otimes \to N(\mathcal{F}\mathcal{I}n_\ast) \) be a generalized \( \infty \)-operad and let \( \text{Fun}'_{N(\mathcal{F}\mathcal{I}n_\ast)}(N(\Delta)^{op}\times \Delta^1, \mathcal{O}^\otimes) \) be the full subcategory of \( \text{Fun}_{N(\mathcal{F}\mathcal{I}n_\ast)}(N(\Delta)^{op}\times \Delta^1, \mathcal{O}^\otimes) \) spanned by those functors which carry every morphism in \( M \) to an inert morphism in \( \mathcal{O}^\otimes \). We wish to prove that composition with the map \( \gamma : N(\Delta)^{op} \times \Delta^1 \to \mathcal{L}M^\otimes \) induces an equivalence of \( \infty \)-categories \( \theta : \text{Alg}_{\mathcal{L}M}(\mathcal{O}) \to \text{Fun}'_{N(\mathcal{F}\mathcal{I}n_\ast)}(N(\Delta)^{op}\times \Delta^1, \mathcal{O}^\otimes) \).

Using Propositions 2.3.2.9 and 2.3.2.11, we may assume that \( q \) factors as a composition

\[
\mathcal{O}^\otimes \xrightarrow{q'} \mathcal{C} \times N(\mathcal{F}\mathcal{I}n_\ast) \to N(\mathcal{F}\mathcal{I}n_\ast),
\]
where \( q' \) exhibits \( \mathcal{O}^\otimes \) as a \( \mathcal{C} \)-family of \( \infty \)-operads. Let \( q_0' : \mathcal{O}^\otimes \to \mathcal{C} \) be the composition of \( q' \) with the projection to \( \mathcal{C} \).

Let \( J \) denote the categorical mapping cylinder of the functor \( \Delta^{op} \times [1] \to \mathcal{L}M^\otimes \) determined by the map \( \gamma \) appearing in Remark 4.2.2.8. More precisely, we can describe \( J \) as follows:
(1) An object of $\mathcal{J}$ is either an object of $\Delta^{op} \times [1]$ or an object of $\text{LM}$.

(2) Morphisms in $\mathcal{J}$ are given by the formulas

$$\text{Hom}_{\mathcal{J}}([n], i), ([n], j)) = \text{Hom}_{\Delta^{op} \times [1]}([n], i), ([n], j))$$

$$\text{Hom}_{\mathcal{J}}((m), S), ((n), T)) = \text{Hom}_{\text{LM}^{\circ}}((m), S), ((n), T))$$

$$\text{Hom}_{\mathcal{J}}((m), S), ([n], 0)) = \text{Hom}_{\text{LM}}((m), S), \text{LCut}([n]))$$

$$\text{Hom}_{\mathcal{J}}((m), S), ([n], 1)) = \text{Hom}_{\text{LM}}((m), S), \text{Cut}([n]))$$

$$\text{Hom}_{\mathcal{J}}(([n], i), ((m), T)) = \emptyset.$$ 

There is a canonical retraction $r$ from $\mathcal{J}$ onto $\text{LM}^{\circ}$, given on objects of $\Delta^{op} \times [1]$ by the formula $r([n], 0) = \text{LCut}([n])$, $r([n], 1) = \text{Cut}([n])$.

We let $\mathcal{X}$ denote the full subcategory of $\text{Fun}_{\mathcal{J}_{\text{fin}}}(\mathcal{N}(\mathcal{J}), \mathcal{O}^{\circ})$ spanned by those functors $f : \mathcal{N}(\mathcal{J}) \to \mathcal{O}^{\circ}$ which satisfy the following conditions:

(i) For every object $([n], i) \in \Delta^{op} \times [1]$, the functor $f$ carries the canonical map $r([n], i) \to ([n], i)$ in $\mathcal{J}$ to an equivalence in $\mathcal{O}^{\circ}$.

(ii) The restriction $f|_{\text{LM}^{\circ}}$ carries inert morphisms in $\text{LM}^{\circ}$ to inert morphisms in $\mathcal{O}^{\circ}$.

Note that conditions (i) and (ii) immediately imply the following:

(iii) The restriction $f|_{(\mathcal{N}(\Delta)^{op} \times \Delta^1)}$ belongs to $\text{Fun}_{\mathcal{J}_{\text{fin}}}(\mathcal{N}(\Delta)^{op} \times \Delta^1, \mathcal{O}^{\circ})$.

Condition (i) is equivalent to the requirement that $f$ is a $q$-left Kan extension of $f|_{\text{LM}^{\circ}}$. Since every functor $f_0 \in \text{Fun}_{\mathcal{J}_{\text{fin}}}(\mathcal{N}(\mathcal{J}), \mathcal{O}^{\circ})$ admits a $q$-left Kan extension $f \in \text{Fun}_{\mathcal{J}_{\text{fin}}}(\mathcal{N}(\mathcal{J}), \mathcal{O}^{\circ})$ (given, for example, by $f_0 \circ r$), Proposition T.4.3.2.15 implies that the restriction map $p : \mathcal{X} \to \text{Alg}_{\text{LM}}(\mathcal{O})$ is a trivial Kan fibration. The map $\theta$ is the composition of a section to $p$ (given by composition with $r$) with the restriction map $p' : \mathcal{X} \to \text{Fun}_{\mathcal{J}_{\text{fin}}}(\mathcal{N}(\Delta)^{op} \times \Delta^1, \mathcal{O}^{\circ})$. It will therefore suffice to show that $p'$ is a trivial Kan fibration. In view of Proposition T.4.3.2.15, this will follow from the following pair of assertions:

(a) Every $f_0 \in \text{Fun}_{\mathcal{J}_{\text{fin}}}(\mathcal{N}(\Delta)^{op} \times \Delta^1, \mathcal{O}^{\circ})$ admits a $q$-right Kan extension $f \in \text{Fun}_{\mathcal{J}_{\text{fin}}}(\mathcal{N}(\mathcal{J}), \mathcal{O}^{\circ})$.

(b) Given $f \in \text{Fun}_{\mathcal{J}_{\text{fin}}}(\mathcal{N}(\mathcal{J}), \mathcal{O}^{\circ})$ satisfying (iii), the functor $f$ is a $q$-right Kan extension of $f_0 = f|_{(\mathcal{N}(\Delta)^{op} \times \Delta^1)}$ if and only if it also satisfies conditions (i) and (ii).

We first prove (a). Fix $f_0 \in \text{Fun}_{\mathcal{J}_{\text{fin}}}(\mathcal{N}(\Delta)^{op} \times \Delta^1, \mathcal{O}^{\circ})$. Then $g_0 \circ f_0$ carries every morphism of $M$ to an equivalence in $\mathcal{C}$. Using the two-out-of-three property, we deduce that $g_0 \circ f_0$ carries every morphism in $\mathcal{N}(\Delta)^{op} \times \Delta^1$ to an equivalence in $\mathcal{C}$. Since $\mathcal{N}(\Delta)^{op} \times \Delta^1$ is a weakly contractible simplicial set, we may assume without loss of generality that $g_0 \circ f_0$ factors as a composition

$$\mathcal{N}(\Delta)^{op} \times \Delta^1 \to \{C\} \hookrightarrow \mathcal{C}$$

for some object $C \in \mathcal{C}$; that is, we may regard $f_0$ as a functor $\mathcal{N}(\Delta)^{op} \times \Delta^1 \to \mathcal{O}^{\circ}$, where $\mathcal{O}^{\circ}$ denotes the $\infty$-operad $\mathcal{O}^{\circ} \times e\{C\}$. Let $q_C : \mathcal{O}^{\circ} \to \mathcal{N}(\text{Fin}_*)$ denote the restriction of $q$ to $\mathcal{O}^{\circ}$.

Fix an object $((n), S) \in \mathcal{L}^{\circ}$. Let $\mathcal{J}$ denote the category $(\Delta^{op} \times [1]) \times_{\mathcal{J}} \mathcal{J}_{((n), S)/}$, and let $g$ denote the composition $\mathcal{N}(\mathcal{J}) \to \mathcal{N}(\Delta)^{op} \times \Delta^1 \overset{f_0}{\longrightarrow} \mathcal{O}^{\circ}$. According to Lemma T.4.3.2.13, it will suffice to show that $g$ admits a $q$-limit in $\mathcal{O}^{\circ}$ (compatible with the evident map $\mathcal{N}(\mathcal{J})^{q} \to \mathcal{N}(\text{Fin}_*)$). The objects of $\mathcal{J}$ can be identified with morphisms $\alpha : ((n), S) \to r([n], i)$ in $\mathcal{L}^{\circ}$. Let $\mathcal{J}_0 \subseteq \mathcal{J}$ denote the full subcategory spanned by those objects for which $\alpha$ is inert. The inclusion $\mathcal{J}_0 \subseteq \mathcal{J}$ has a right adjoint and therefore induces a right cofinal map $\mathcal{N}(\mathcal{J}_0) \to \mathcal{N}(\mathcal{J})$. Consequently, it will suffice to show that $g_0 = g|_{\mathcal{N}(\mathcal{J}_0)}$ admits a $q$-limit in $\mathcal{O}^{\circ}$ (compatible with the evident map $\mathcal{N}(\mathcal{J}_0)^{q} \to \mathcal{N}(\text{Fin}_*)$).
4.2. LEFT AND RIGHT MODULES

Let $\mathcal{J}_1$ denote the full subcategory of $\mathcal{J}_0$ spanned by the morphism which are either of the form $\rho^i : ((n), S) \to r([0], 0)$ where $j \in S$, $\rho^j : ((n), S) \to r([1], 1)$ when $j \notin S$, or $((n), S) \to r([0], 1) \simeq (0), \emptyset)$. Let $g_1 = g_0|N(\mathcal{J}_1)$. We note that $N(\mathcal{J}_1)$ is weakly contractible. Since $g_0 \in \text{Fun}_{\mathcal{J}((\mathcal{J}_n))}(N(\Delta)^{op} \times \Delta^1, \mathcal{O})^\circ$, $g_1$ carries every morphism in $N(\mathcal{J}_1)$ to an inert morphism in $\mathcal{O}^\circ$. We first show that $g_1$ can be extended to a $qC$-limit diagram in $\mathcal{O}^\circ$ (compatible with the map $N(\mathcal{J}_1)^\circ \to N(\mathcal{J}_n)$).

Let $\mathcal{J}_2$ be the full subcategory of $\mathcal{J}_1$ obtained by removing objects of the form $((n), S) \to r([0], 1)$. Note that $\mathcal{J}_2$ is isomorphic to the discrete category with object set $\{1, 2, \ldots, n\}$. Since $\mathcal{O}^\circ$ is an $\infty$-operad, the functor $g_2 = g_1|N(\mathcal{J}_2)$ can be extended to a $qC$-limit diagram $\overline{g}_2$ (lying over the evident map $N(\mathcal{J}_2)^\circ \to N(\mathcal{J}_n))$.

Let $q'$ exhibit $\mathcal{O}^\circ$ as a $\mathcal{C}$-family of $\infty$-operads, $\overline{g}_2$ is also a $q'$-limit diagram. Note that $g_1$ is a $qC$-right Kan extension of $g_2$, so (by Lemma T.4.3.2.7, we can extend $g_2$ to a $qC$-limit diagram $\overline{g}_2 : N(\mathcal{J}_2)^\circ \to \mathcal{O}^\circ$). Since $g_1$ is also a $q'$-right Kan extension of $g_2$, $\overline{g}_2$ is also a $q'$-limit diagram. We claim that $\overline{g}_2$ is also a $q'$-limit diagram. In view of Proposition T.4.3.1.5, it will suffice to show that $q' \circ \overline{g}_2$ is a $q''$-limit diagram in $\mathcal{C} \times N(\mathcal{J}_n)$. Equivalently, we must show that the constant functor $q'_0 \circ \overline{g}_2$ is a limit diagram in $\mathcal{C}$, which follows from the fact that the simplicial set $N(\mathcal{J}_1)$ is weakly contractible (Corollary T.4.4.4.10). This completes the proof of (a). Moreover, the proof shows that an extension $f : N(\mathcal{J}) \to \mathcal{O}^\circ$ is a $qC$-right Kan extension of $f_0$ if and only if it satisfies the following condition:

(i') For every object $((n), S) \in \mathcal{LM}^\circ$ as above and every morphism $\alpha : ((n), S) \to ([m], i)$ in $\mathcal{J}$ belonging to $\mathcal{J}_1$, the morphism $f(\alpha)$ is inert in $\mathcal{O}^\circ$.

To prove (b), it will suffice to show that if $f \in \text{Fun}_{\mathcal{J}((\mathcal{J}_n))}(N(\mathcal{J}), \mathcal{O}^\circ)$ satisfies condition (iii), then it satisfies conditions (i) and (ii) if and only if it satisfies condition (i'). We first prove the “only if” direction. Assume that $f \in \mathcal{X}$, and let $\alpha : (\langle n \rangle, S) \to ([m], i)$ be as in (i'). Then $\alpha$ factors as a composition

\[(\langle n \rangle, S) \xrightarrow{\alpha'} r([m], i) \xrightarrow{\alpha''} ([m], i),\]

where $\alpha'$ is inert (so that $f(\alpha')$ is inert by (ii)) and $f(\alpha'')$ is an equivalence by virtue of (i).

Suppose now that $f$ satisfies (i') and (iii). We first show that $f$ satisfies (i). Fix an object $([n], i)$ in $N(\Delta)^{op} \times \Delta^1$; we wish to show that $f$ carries the canonical map $\alpha : r([n], i) \to ([n], i)$ to an equivalence in $\mathcal{O}^\circ$. For $1 \leq j \leq n$, let $\beta_j : ([m], i) \to ([1], 1)$ denote the be the map carrying $[1]$ to the interval $\{j - 1, j\} \subseteq [n]$, and if $i = 0$ let $\beta_0 : ([n], i) \to ([0], 0)$ be the map induced by the inclusion $[0] \simeq \{n\} \hookrightarrow [n]$. Condition (iii) guarantees that the maps $\{f(\beta_j)\}_{1 \leq j \leq n}$ determine a $q'$-product diagram in $\mathcal{O}^\circ$, and condition (i') guarantees that the composite maps $\{f(\beta_j \circ \alpha)\}_{1 \leq j \leq n}$ also determine a $q'$-product diagram in $\mathcal{O}^\circ$. It follows from the uniqueness of relative limits that $f(\alpha)$ is an equivalence in $\mathcal{O}^\circ$, as desired.

It remains to show that $f$ satisfies (ii). For every object $((n), S) \in \mathcal{LM}^\circ$, we have a commutative diagram

\[
\begin{array}{ccc}
((n), S) & \xrightarrow{\alpha} & ([0], 0) \\
\downarrow & & \downarrow \alpha' \alpha'' \\
([0], 1)
\end{array}
\]

Condition (i') implies that $(q'_0 \circ f)(\alpha'')$ and $(q' \circ f)(\alpha')$ are equivalences in $\mathcal{C}$, so that $(q'_0 \circ f)(\alpha)$ is an equivalence in $\mathcal{C}$. It follows that $q'_0 \circ f$ carries every morphism in $\mathcal{LM}^\circ$ to an equivalence in $\mathcal{C}$. The simplicial set $\mathcal{LM}^\circ$ is weakly contractible (it has a final object, given by $((0), \emptyset)$); we may therefore without loss of generality that $f|\mathcal{LM}^\circ$ is the constant map $\mathcal{LM}^\circ \to \{C\} \hookrightarrow \mathcal{C}$, for some $C \in \mathcal{C}$. We wish to show that $f|\mathcal{LM}^\circ$ defines a map of $\infty$-operads $\mathcal{LM}^\circ \to \mathcal{O}^\circ$. By virtue of Remark 2.1.2.9, it will suffice to show that $f(\alpha)$ is inert whenever $\alpha$ is an inert morphism of $\mathcal{LM}^\circ$ of the form $((n), S) \to ([1], T)$. Write $((1), T) = r([i], i)$ for $i \in \{0, 1\}$. Since the map $f((1), T) \to f([i], i)$ is an equivalence by (i), it will suffice to show that the composite map $f((n), S) \to f((1), T) \to f([i], i)$ is inert, which follows immediately from (i').

\[\Box\]
4.2.3 Limits and Colimits of Modules

Let $A$ be a ring and suppose we are given a collection of $A$-modules $\{M_i\}_{i \in I}$. Then the abelian groups

$$\prod_{i \in I} M_i \bigoplus_{i \in I} M_i$$

inherit $A$-module structures. Moreover, the resulting $A$-modules can be identified with the product and coproduct of the family $\{M_i\}_{i \in I}$ in the category of $A$-modules. We can summarize the situation as follows: the category of $A$-modules admits products and coproducts, and the forgetful functor $U$ from the category of $A$-modules to the category of abelian groups preserves products and coproducts. In fact, $U$ preserves all limits and colimits.

Our goal in this section is to show that this is a general phenomenon. Let $A$ be an algebra object of an arbitrary monoidal $\infty$-category $C$, and let $M$ be an $\infty$-category which is left-tensored over $C$. We can summarize our results as follows:

1. Let $K$ be a simplicial set such that $M$ admits $K$-indexed limits. Then $\text{LMod}_A(M)$ admits $K$-indexed limits, and the forgetful functor $\text{LMod}_A(M) \to M$ preserves $K$-indexed limits (Corollary 4.2.3.3).

2. Let $K$ be a simplicial set such that $M$ admits $K$-indexed colimits and the tensor product functor $M \to A \otimes M$ preserves $K$-indexed colimits. Then $\text{LMod}_A(M)$ admits $K$-indexed colimits, and the forgetful functor $\text{LMod}_A(M) \to M$ preserves $K$-indexed colimits (Corollary 4.2.3.5).

We begin with the study of limits in $\text{LMod}_A(M)$. In fact, we will work a little bit more generally, and consider relative limits with respect to the forgetful functor $\text{LMod}(M) \to \text{Alg}(C)$ (we refer the reader to §T.4.3 for a discussion of relative limits in general). We have the following general result:

**Proposition 4.2.3.1.** Let $\mathcal{C}$ be a monoidal $\infty$-category and let $M$ be an $\infty$-category which is left-tensored over $\mathcal{C}$. Let $K$ be a simplicial set such that $M$ admits $K$-indexed limits, and let $\theta : \text{LMod}(M) \to \text{Alg}(\mathcal{C})$ be the forgetful functor. Then:

1. For every diagram

$$
\begin{array}{ccc}
K & \rightarrow & \text{LMod}(M) \\
\downarrow & & \downarrow \theta \\
K^\triangleleft & \rightarrow & \text{Alg}(\mathcal{C})
\end{array}
$$

there exists a dotted arrow as indicated, which is a $\theta$-limit diagram.

2. An arbitrary map $\overline{\theta} : K^\triangleleft \rightarrow \text{LMod}(M)$ is a $\theta$-limit diagram if and only if the induced map $K^\triangleleft \rightarrow M$ is a limit diagram.

**Proof.** Let $\theta' : \Delta \text{LMod}(M) \to \Delta \text{Alg}(\mathcal{C})$ be the forgetful functor. By virtue of Propositions 4.1.2.15 and 4.2.2.11, it will suffice to prove the following analogues of (1) and (2):

1. For every diagram

$$
\begin{array}{ccc}
K & \rightarrow & \Delta \text{LMod}(M) \\
\downarrow & & \downarrow \theta' \\
K^\triangleleft & \rightarrow & \Delta \text{Alg}(\mathcal{C})
\end{array}
$$

there exists a dotted arrow as indicated, which is a $\theta'$-limit diagram.

2. An arbitrary map $\overline{\theta'} : K^\triangleleft \rightarrow \Delta \text{LMod}(M)$ is a $\theta'$-limit diagram if and only if the induced map $K^\triangleleft \rightarrow M$ is a limit diagram.
4.2. LEFT AND RIGHT MODULES

Let $\mathcal{M}\overset{q}{\to} \mathcal{C}\overset{p}{\to} \text{N}(\Delta)^{op}$ be as in Notation 4.2.2.16. For each $n \geq 0$, the equivalence $\mathcal{M}_{[n]} \simeq \mathcal{C}_{[n]} \times \mathcal{M}$ implies the following:

(1') For every diagram

\[
\begin{array}{ccc}
K & \to & M_{[n]} \\
\downarrow & & \downarrow \beta \\
K^q & \to & C_{[n]} \\
\end{array}
\]

there exists a dotted arrow as indicated, which is a $q_{[n]}$-limit diagram.

(2') An arbitrary diagram $K^q \to M_{[n]}^q$ is a $q_{[n]}$-limit diagram if and only if the composite map $K^q \to M_{[n]}^q \to M$ is a limit diagram.

Combining this observation with Corollary T.4.3.1.15, we deduce:

(1'') For every diagram

\[
\begin{array}{ccc}
K & \to & M_{[n]} \\
\downarrow & & \downarrow \beta \\
K^q & \to & C_{[n]} \\
\end{array}
\]

there exists a dotted arrow as indicated, which is a $q$-limit diagram.

(2'') An arbitrary diagram $K^q \to M_{[n]}^q$ is a $q$-limit diagram if and only if the composition $K^q \to M_{[n]}^q \to M$ is a limit diagram.

Let $\Delta \text{LMod}'(\mathcal{M})$ be the full subcategory of $\text{Map}_{\text{N}(\Delta)^{op}}(\text{N}(\Delta)^{op}, \mathcal{M})$ spanned by those objects whose image in $\text{Fun}_{\text{N}(\Delta)^{op}}(\text{N}(\Delta)^{op}, \mathcal{M})$ belongs to $\Delta \text{Alg}(\mathcal{C})$. Combining (1''), (2''), and Lemma 3.2.2.9, we deduce:

(1'') For every diagram

\[
\begin{array}{ccc}
K & \to & \Delta \text{LMod}'(\mathcal{M}) \\
\downarrow & & \downarrow \beta'' \\
K^q & \to & \Delta \text{Alg}(\mathcal{C}) \\
\end{array}
\]

there exists a dotted arrow as indicated, which is a $\beta''$-limit diagram.

(2'') An arbitrary map $\overline{p} : K^q \to \Delta \text{LMod}'(\mathcal{M})$ is a $\beta''$-limit diagram if and only if, for every $n \geq 0$, the composite map $K^q \to M_{[n]}^q \to M$ is a limit diagram.

To deduce (1') from these assertions, it will suffice to show that if $\overline{g} : K^q \to \Delta \text{LMod}'(\mathcal{M})$ satisfies the hypothesis of (2'') and $g = \overline{g}[K$ factors through $\Delta \text{LMod}(\mathcal{M})$, then $\overline{g}$ factors through $\Delta \text{LMod}(\mathcal{M})$. Let $f : [m] \to [n]$ be an inert morphism in $\Delta$ such that $f(m) = n$. Then $f$ induces a natural transformation $\overline{g}_{[n]} \to \overline{g}_{[m]}$ of functors $K^q \to M^q$. We wish to show that this natural transformation is $(p \circ q)$-coCartesian. Since $f(m) = n$, we have a homotopy commutative diagram

\[
\begin{array}{ccc}
\mathcal{M}_{[n]} & \to & M_{[n]}^q \\
\downarrow \alpha & & \downarrow \beta \\
\mathcal{M} & \to & M_{[m]}^q \\
\end{array}
\]
and it suffices to show that the associated transformation \( \tilde{t} : \alpha \circ \mathcal{G}_{[m]} \rightarrow \beta \circ \mathcal{G}_{[m]} \) is an equivalence. Our hypothesis implies that \( \tilde{t} \) restricts to an equivalence \( t : \alpha \circ g_{[m]} \rightarrow \beta \circ g_{[m]} \). Since \( \mathcal{G} \) satisfies (2'), the maps \( \alpha \circ \mathcal{G}_{[m]} \) and \( \beta \circ \mathcal{G}_{[m]} \) are both limit diagrams in \( \mathcal{M} \). It follows that \( \tilde{t} \) is an equivalence as well, as desired.

We now complete the proof by observing that if \( \mathcal{G} : K^\otimes \rightarrow \Delta \text{LMod}^\prime(\mathcal{M}) \) factors through \( \Delta \text{LMod}(\mathcal{M}) \), then the criteria of (2') and (2'') are equivalent.

**Corollary 4.2.3.2.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category, \( \mathcal{M} \) an \( \infty \)-category which is left-tensored over \( \mathcal{C} \), and \( \theta : \text{LMod}(\mathcal{M}) \rightarrow \text{Alg}(\mathcal{C}) \) the forgetful functor. Then \( \theta \) is a Cartesian fibration. Moreover, a morphism \( f \) in \( \text{LMod}(\mathcal{M}) \) is \( \theta \)-Cartesian if and only if the image of \( f \) in \( \mathcal{M} \) is an equivalence.

**Proof.** Apply Proposition 4.2.3.1 in the case \( K = \Delta^0 \).

**Corollary 4.2.3.3.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category, \( \mathcal{M} \) an \( \infty \)-category which is left-tensored over \( \mathcal{C} \), and \( \theta : \text{LMod}(\mathcal{M}) \rightarrow \text{Alg}(\mathcal{C}) \) the forgetful functor. Let \( A \) be an algebra object of \( \mathcal{C} \). Let \( K \) be a simplicial set such that \( \mathcal{M} \) admits \( K \)-indexed limits. Then:

1. The \( \infty \)-category \( \text{LMod}_A(\mathcal{M}) \) admits \( K \)-indexed limits.
2. A map \( \mathcal{P} : K^\otimes \rightarrow \text{LMod}_A(\mathcal{M}) \) is a limit diagram if and only if the induced map \( K^\otimes \rightarrow \mathcal{M} \) is a limit diagram.
3. Given a morphism \( \phi : B \rightarrow A \) of algebra objects of \( \mathcal{A} \), the induced functor \( \text{LMod}_A(\mathcal{M}) \rightarrow \text{LMod}_B(\mathcal{M}) \) preserves \( K \)-indexed limits.

We now turn to the problem of constructing colimits in \( \infty \)-categories of modules. We begin with the following very general principle:

**Proposition 4.2.3.4.** Let \( \mathcal{A} \subseteq \mathcal{Cat}_\infty \) be a subcategory of the \( \infty \)-category of (not necessarily small) \( \infty \)-categories. Assume that \( \mathcal{A} \) has the following properties:

1. The \( \infty \)-category \( \mathcal{A} \) admits small limits, and the inclusion \( \mathcal{A} \subseteq \mathcal{Cat}_\infty \) preserves small limits.
2. If \( X \) belongs to \( \mathcal{A} \), then \( \text{Fun}(\Delta^1, X) \) belongs to \( \mathcal{A} \).
3. If \( X \) and \( Y \) belong to \( \mathcal{C} \), then a functor \( X \rightarrow \text{Fun}(\Delta^1, Y) \) is a morphism in \( \mathcal{A} \) if and only if, for every vertex \( v \) of \( \Delta^1 \), the composite functor \( X \rightarrow \text{Fun}(\Delta^1, Y) \rightarrow \text{Fun}(\{v\}, Y) \cong Y \) is a morphism of \( \mathcal{A} \).

Let \( \mathcal{C} \) be a monoidal \( \infty \)-category, \( A \) an algebra object of \( \mathcal{C} \), \( M \) an \( \infty \)-category which is left-tensored over \( \mathcal{C} \). Suppose \( M \) is an object of \( \mathcal{A} \), and that the functor \( A \otimes - : M \rightarrow M \) is a morphism of \( \mathcal{A} \). Then:

1. The \( \infty \)-category \( \text{Mod}_A(M) \) is an object of \( \mathcal{A} \).
2. For every \( \infty \)-category \( \mathcal{N} \) belonging to \( \mathcal{A} \), a functor \( \mathcal{N} \rightarrow \text{Mod}_A(M) \) is a morphism in \( \mathcal{A} \) if and only if the composite functor \( \mathcal{N} 

In particular, the forgetful functor \( \text{Mod}_A(M) \rightarrow M \) is a morphism in \( \mathcal{A} \).

**Proof.** Let \( p : M^\otimes \rightarrow C^\otimes \) exhibit \( M \) as left-tensored over \( \mathcal{C} \). Form a pullback diagram

\[
\begin{array}{ccc}
X & \rightarrow & M^\otimes \\
\downarrow p' & & \downarrow p \\
\mathcal{N}(\Delta)^\otimes & \rightarrow & C^\otimes.
\end{array}
\]

We observe that \( p' \) is a locally coCartesian fibration (Lemma 4.2.2.19), each fiber of \( p' \) is equivalent to \( M \), and each of the associated functors can be identified with an iterate of the functor \( A \otimes - : M \rightarrow M \). It follows from Proposition T.5.4.7.11 that \( \Delta \text{LMod}_A(M) \in \mathcal{A} \), so that \( \text{LMod}_A(M) \in \mathcal{A} \) by Corollary 4.2.2.15.
4.2. LEFT AND RIGHT MODULES

Now suppose that \( f : N \rightarrow \text{Mod}_A(M) \) is as in (2). Using Proposition T.5.4.7.11 and Corollary 4.2.2.15, we conclude that \( f \) is a morphism of \( A \) if and only if, for every \( n \geq 0 \), the composite map \( N \rightarrow \text{Mod}_A(M) \rightarrow X_{[n]} \) belongs to \( A \). We complete the proof by observing that each of the functors \( \text{Mod}_A(M) \rightarrow X_{[n]} \) is equivalent to the forgetful functor \( \text{Mod}_A(M) \rightarrow M \).

**Corollary 4.2.3.5.** Let \( M \) be an \( \infty \)-category which is left-tensored over a monoidal \( \infty \)-category \( \mathcal{C} \), let \( A \) be an algebra object of \( \mathcal{C} \), and let \( \theta : \text{LMod}_A(M) \rightarrow M \) denote the forgetful functor. Let \( p : K \rightarrow \text{LMod}_A(M) \) be a diagram and let \( p_0 = \theta \circ p \). Suppose that \( p_0 \) can be extended to an operadic colimit diagram \( \overline{p}_0 : K^\circ \rightarrow M \) (in other words, \( \overline{p}_0 \) has the property that for every object \( C \in \mathcal{C} \), the composite map

\[
K^\circ \xrightarrow{\overline{p}_0} M \xrightarrow{\circ C} M
\]

is also a colimit diagram in \( M \)). Then:

1. The diagram \( p \) extends to a colimit diagram \( \overline{p} : K^\circ \rightarrow \text{LMod}_A(M) \).

2. Let \( \overline{p} : K^\circ \rightarrow \text{LMod}_A(M) \) be an arbitrary extension of \( p \). Then \( \overline{p} \) is a colimit diagram if and only if \( \theta \circ \overline{p} \) is a colimit diagram.

**Proof.** Let \( q : M^\otimes \rightarrow \mathcal{C}^\otimes \) be the locally coCartesian fibration defined in Notation 4.2.2.16. The algebra object \( A \) determines a map \( N(\Delta)^{\text{op}} \rightarrow \mathcal{C}^\otimes \). Let \( X \) denote the fiber product \( \text{Fun}(\Delta)^{\text{op}}, M^\otimes \). The forgetful functor \( \text{LMod}_A(M) \rightarrow \Delta \text{LMod}_A(M) \) and let \( \text{LMod}_A(M) \rightarrow \Delta \text{LMod}_A(M) \) be the equivalence of Corollary 4.2.2.15. It follows from Lemma 3.2.2.9 that the composite map \( K \rightarrow \text{LMod}_A(M) \rightarrow \Delta \text{LMod}_A(M) \) can be extended to a colimit diagram in \( \text{Fun}(\Delta)^{\text{op}}, \mathcal{C}^\otimes \), that this diagram factors through \( \Delta \text{LMod}_A(M) \), and that its image in \( M \) is a colimit diagram. This proves (1) and the "only if" direction of (2). To prove the "if" direction of (2), let us suppose we are given an arbitrary extension \( \overline{p} : K^\circ \rightarrow \text{LMod}_A(M) \), carrying the cone point to a left \( A \)-module \( M \). Then \( \overline{p} \) determines a map \( \alpha : \text{lim}(p) \rightarrow M \). If the image of \( \overline{p} \) in \( M \) is a colimit diagram, then the image of \( \alpha \) in \( M \) is a colimit diagram. Since the forgetful functor \( \text{LMod}_A(M) \rightarrow M \) is conservative (Corollary 4.2.3.2), we deduce that \( \alpha \) is an equivalence. It follows that \( \overline{p} \) is a colimit diagram as desired.

**Remark 4.2.3.6.** In the situation of Corollary 4.2.3.5, any colimit diagram \( \overline{f} : K^\circ \rightarrow \text{LMod}_A(M) \) is also a \( q \)-colimit diagram, where \( q \) denotes the projection \( \text{LM}(M) \rightarrow \text{Alg}(\mathcal{C}) \). This follows immediately from Corollary T.4.3.1.16, since \( q \) is a Cartesian fibration (Corollary 4.2.3.2).

**Corollary 4.2.3.7.** Let \( \mathcal{C} \) be an \( \infty \)-category equipped with a monoidal structure and let \( M \) be an \( \infty \)-category which is left-tensored over \( \mathcal{C} \). Suppose that \( M \) is presentable and that, for each \( C \in \mathcal{C} \), the functor \( C \otimes \bullet : M \rightarrow M \) preserves small colimits. Then:

1. For every \( A \in \text{Alg}(\mathcal{C}) \), the \( \infty \)-category \( \text{LMod}_A(M) \) is presentable.

2. For every morphism \( A \rightarrow B \) of algebra objects of \( \mathcal{C} \), the associated functor \( \text{LMod}_B(M) \rightarrow \text{LMod}_A(M) \) preserves small limits and colimits.

3. The forgetful functor \( \theta : \text{LMod}(M) \rightarrow \text{Alg}(\mathcal{C}) \) is a presentable fibration (Definition T.5.5.3.2).

**Proof.** Assertion (1) follows from Proposition 4.2.3.4 as in the proof of Corollary 4.2.3.5. To prove (2), we observe that Corollary 4.2.3.2 implies that the diagram

\[
\begin{array}{ccc}
\text{LMod}_B(M) & \longrightarrow & \text{LMod}_A(M) \\
\downarrow & & \downarrow \\
M & \longrightarrow & M
\end{array}
\]

commutes up to homotopy. Assertion (2) then follows immediately from Corollaries 4.2.3.3 and 4.2.3.5. Assertion (3) follows from (1) and (2), by virtue of Proposition T.5.5.3.3. \( \square \)
Remark 4.2.3.8. Under the hypotheses of Corollary 4.2.3.7, if $A \to B$ is a morphism of algebra objects of $\mathcal{C}$, then the forgetful functor $\psi : \text{LMod}_B(M) \to \text{LMod}_A(M)$ admits both left and right adjoints (Corollary T.5.5.2.9). In §4.4.3 we will prove the existence of a left adjoint to $\psi$ under much weaker assumptions (Proposition 4.6.2.17).

4.2.4 Free Modules

Let $A$ be an associative ring and $M_0$ an abelian group. The tensor product $M = A \otimes M_0$ has the structure of a left $A$-module, given by the map

$$A \otimes M \simeq A \otimes (A \otimes M_0) \simeq (A \otimes A) \otimes M_0 \to A \otimes M_0 \simeq M.$$

Moreover, $M$ is characterized up to isomorphism by the condition that it is the free left $A$-module generated by $M_0$. More precisely, there exists a map of abelian groups $\phi : M_0 \to M$ with the following universal property: for every left $A$-module $M$, composition with $\phi$ induces a bijection $\text{Hom}_A(M, N) \to \text{Hom}(M_0, N)$, where $\text{Hom}_A(M, N)$ denotes the set of $A$-module homomorphisms from $M$ to $N$ and $\text{Hom}(M_0, N)$ the set of abelian group homomorphisms from $M_0$ to $N$.

Our first goal in this section is to generalize the above discussion to the $\infty$-categorical setting. We begin with a point of notation: if $\mathcal{C}^\otimes$ is a planar $\infty$-operad and $\mathcal{M}$ is an $\infty$-category weakly enriched over $\mathcal{C}^\otimes$, then evaluation on the object $m \in \mathcal{L}M$ determines a forgetful functor $\theta : \text{LMod}_A(M) \to \mathcal{M}$, for each $A \in \text{Alg}(\mathcal{C})$. We will generally abuse notation by not distinguishing between an object $M \in \text{LMod}_A(M)$ and its image $\theta(M) \in \mathcal{M}$.

Definition 4.2.4.1. Let $\mathcal{C}^\otimes$ be a monoidal $\infty$-category and let $\mathcal{M}$ be an $\infty$-category left-tensored over $\mathcal{C}^\otimes$. Suppose we are given an algebra object $A \in \text{Alg}(\mathcal{C})$, a left $A$-module $M \in \text{LMod}_A(M)$, and a morphism $\lambda : M_0 \to M$ in $\mathcal{M}$. We will say that $\lambda$ exhibits $M$ as a free left $A$-module generated by $M_0$ if the induced map

$$A \otimes M_0 \xrightarrow{id \otimes \lambda} A \otimes M \to M$$

is an equivalence in $\mathcal{M}$.

The main result of this section can be stated as follows:

Proposition 4.2.4.2. Let $\mathcal{C}^\otimes$ be a monoidal $\infty$-category and $\mathcal{M}$ an $\infty$-category which is left-tensored over $\mathcal{C}^\otimes$. Suppose further that we are given objects $A \in \text{Alg}(\mathcal{C})$, $M_0 \in \mathcal{M}$. Then:

1. There exists an object $M \in \text{LMod}_A(M)$ and a morphism $\lambda : M_0 \to M$ in $\mathcal{M}$ which exhibits $M$ as a free left $A$-module generated by $M_0$.

2. Let $M \in \text{LMod}_A(M)$ and let $\lambda : M_0 \to M$ be a morphism which exhibits $M$ as a free left $A$-module generated by $M_0$. For every pair of objects $B \in \text{Alg}(\mathcal{C})$, $N \in \text{LMod}_B(M)$, composition with $\lambda$ induces a homotopy equivalence

$$\text{Map}_{\text{LMod}(M)}((A, M), (B, N)) \to \text{Map}_{\text{Alg}(\mathcal{C})}(A, B) \times \text{Map}_{\mathcal{M}}(M_0, N).$$

Proof. The action of $\mathcal{C}^\otimes$ on $\mathcal{M}$ is encoded by a coCartesian fibration of $\infty$-operads $\mathcal{O}^\otimes \to \mathcal{L}M^\otimes$ such that $\mathcal{O}_a^\otimes \simeq \mathcal{C}^\otimes$ and $\mathcal{O}_m \simeq \mathcal{M}$. Let $\mathcal{L}M_{a}^\otimes$ be the subcategory of $\mathcal{L}M^\otimes$ spanned by all objects, together with those morphisms $\alpha : (\langle n \rangle, S') \to (\langle n' \rangle, S')$ such that $\alpha^{-1}(SU\{*\}) = S'U\{*\}$. The inclusion $\mathcal{Ass}^\otimes \hookrightarrow \mathcal{L}M^\otimes$ of Remark 4.2.1.10 extends to an isomorphism $\mathcal{Ass}^\otimes \boxtimes \mathcal{Triv}^\otimes \simeq \mathcal{L}M_{a}^\otimes$, which carries the unique object of $\mathcal{Triv}$ to $m$. Using Theorem 2.2.3.6 and Example 2.1.3.5, we deduce that the forgetful functor $\mathcal{Ass}_{\mathcal{L}M_{a}^\otimes} / \mathcal{L}M_{a}^\otimes(\mathcal{O}) \to \mathcal{Ass}(\mathcal{C}) \times \mathcal{M}$ is an equivalence of $\infty$-categories.

The $\infty$-category $\mathcal{L}M_{0,act}^\otimes \times \mathcal{L}M_{act}^\otimes(\mathcal{L}M_{act}^\otimes)/a$ contains $id : a \to a$ as a final object, and the $\infty$-category $\mathcal{L}M_{0,act}^\otimes \times \mathcal{L}M_{act}^\otimes(\mathcal{L}M_{act}^\otimes)/m$ contains the unique active map $(\langle 2 \rangle, \{1\}) \to m$ as a final object. Note that if
X ∈ Alg_{LM_a / LM}(0) corresponds to a pair \((A, M_0) ∈ \text{Alg}(\mathcal{C}) × \mathcal{M}\) and \(X' ∈ \text{Alg}_{LM}(0)\) to a pair \((A', M)\), then a natural transformation \(γ : X → X'\) exhibits \(X'\) as the free \(\mathcal{LM}\)-algebra object generated by \(X\) (in the sense of Definition 3.1.3.1) if and only if \(γ\) induces an equivalence \(A ∼ A'\) in \(\text{Alg}(\mathcal{C})\) and a map \(M_0 → M\) in \(\mathcal{M}\) which exhibits \(M\) as the free left \(A'\)-module generated by \(M_0\) (in the sense of Definition 4.2.4.1). Assertion (1) now follows immediately from Proposition 3.1.3.3 and assertion (2) from Proposition 3.1.3.2.

From Proposition 4.2.4.2, we can immediately deduce the following uniqueness result for free modules:

**Corollary 4.2.4.3.** Let \(\mathcal{C}^\otimes\) be a monoidal \(\infty\)-category containing an algebra object \(A\), and let \(\mathcal{M}\) be an \(\infty\)-category left-tensored over \(\mathcal{C}^\otimes\) containing an object \(M_0\). Suppose we are given objects \(M, M' ∈ \text{LMod}_A(\mathcal{M})\), together with morphisms \(λ : M_0 → M, λ' : M_0 → M'\) in \(\mathcal{M}\) which exhibit \(M\) and \(M'\) as free left \(A\)-modules generated by \(M_0\). Then there exists a morphism \(φ : M → M'\) in \(\text{LMod}_A(\mathcal{M})\) which extends to a commutative diagram

\[
\begin{array}{ccc}
M & \xrightarrow{φ} & M' \\
\downarrow{λ} & & \downarrow{λ'} \\
M_0 & & M_0
\end{array}
\]

in \(\mathcal{M}\). The morphism \(φ\) is uniquely determined up to homotopy and is an equivalence in \(\text{LMod}_A(\mathcal{M})\).

**Corollary 4.2.4.4.** Let \(\mathcal{C}^\otimes\) be a monoidal \(\infty\)-category and \(\mathcal{M}\) an \(\infty\)-category which is left-tensored over \(\mathcal{C}^\otimes\). Then the forgetful functor \(G : \text{LMod}(\mathcal{M}) → \text{Alg}(\mathcal{C}) × \mathcal{M}\) admits a left adjoint \(F\), given informally by \(F(A, M_0) = (A, M) ∈ \text{LMod}(\mathcal{M})\), where \(M\) is a free left \(A\)-module generated by \(M_0\).

**Remark 4.2.4.5.** Corollary 4.2.4.4 shows that that a free left \(A\)-module generated by \(M_0 ∈ \mathcal{M}\) depends functorially on the pair \((A, M_0)\).

If we regard the algebra \(A ∈ \text{Alg}(\mathcal{C})\) as fixed, the above results take a slightly simpler form:

**Corollary 4.2.4.6.** Let \(\mathcal{C}^\otimes\) be a monoidal \(\infty\)-category and \(\mathcal{M}\) an \(\infty\)-category which is left-tensored over \(\mathcal{C}^\otimes\). Let \(A ∈ \text{Alg}(\mathcal{C})\), \(M ∈ \text{LMod}_A(\mathcal{M})\), and suppose there exists a map \(λ : M_0 → M\) in \(\mathcal{M}\) which exhibits \(M\) as the free \(A\)-module generated by \(M_0\). Then for any \(N ∈ \text{LMod}_A(\mathcal{M})\), composition with \(λ\) induces a homotopy equivalence \(\text{Map}_{\text{LMod}_A(\mathcal{M})}(M, N) → \text{Map}_{\mathcal{M}}(M_0, N)\).

**Corollary 4.2.4.7.** Let \(\mathcal{C}^\otimes\) be a monoidal \(\infty\)-category containing an algebra object \(A ∈ \text{Alg}(\mathcal{C})\). Regard \(\mathcal{C}\) as left-tensored over itself and \(A\) as a left module over itself (as in Example 4.2.1.17). Let \(1_C\) be the unit object of \(\mathcal{C}\) and \(M\) an object of \(\text{LMod}_A(\mathcal{C})\). Then composition with the unit map of \(A\) induces a homotopy equivalence \(\text{Map}_{\text{LMod}_A(\mathcal{C})}(A, M) → \text{Map}_{\mathcal{C}}(1_C, M)\).

**Proof.** Apply Corollary 4.2.4.6 to the unit map \(1 → A\).

**Corollary 4.2.4.8.** Let \(\mathcal{C}\) be a monoidal \(\infty\)-category and let \(\mathcal{M}\) be an \(\infty\)-category which is left-tensored over \(\mathcal{C}\). Let \(A ∈ \text{Alg}(\mathcal{C})\). Then the forgetful functor \(G : \text{LMod}_A(\mathcal{M}) → \mathcal{M}\) admits a left adjoint \(F\), which carries each \(M_0 ∈ \mathcal{M}\) to a free left \(A\)-module generated by \(M_0\). The composition \(G ◦ F : \mathcal{M} → \mathcal{M}\) is the functor given by tensor product with \(A\).

Corollary 4.2.4.8 guarantees that the theory of modules over a trivial algebra is very simple.

**Proposition 4.2.4.9.** Let \(\mathcal{C}^\otimes\) be a monoidal \(\infty\)-category and \(\mathcal{M}\) an \(\infty\)-category which is left-tensored over \(\mathcal{C}\). Let \(A\) be an algebra object of \(\text{Alg}(\mathcal{C})\) such that the unit map \(1_C → A\) is an equivalence in \(\mathcal{C}\). Then the forgetful functor \(G : \text{LMod}_A(\mathcal{M}) → \mathcal{M}\) is an equivalence of \(\infty\)-categories.
Proof. Let \( F \) be the left adjoint to \( G \) supplied by Corollary 4.2.4.8, and let

\[
u : \text{id}_M \to G \circ F, \quad v : F \circ G \to \text{id}_M
\]

be a compatible unit and counit for the adjunction. We wish to prove that \( u \) and \( v \) are equivalences of functors.

We first consider the functor \( u \). Corollary 4.2.4.8 implies that the composition \( G \circ F \) can be identified with the functor \( M \to A \otimes M \). The unit map \( u \) is given by tensor product with the unit map \( u_0 : 1_C \to A \) of the algebra \( A \). By hypothesis, \( u_0 \) is an equivalence in \( \mathcal{C} \), so that \( u \) is an equivalence in \( \text{Fun}(\mathcal{M}, \mathcal{M}) \).

Note that a morphism \( (A_0, M_0) \to (A_1, M_1) \) in \( \text{LMod}(\mathcal{M}) \) is an equivalence if and only if the induced map \( A_0 \to A_1 \) is an equivalence in \( \mathcal{C} \) and the induced map \( M_0 \to M_1 \) is an equivalence in \( \mathcal{M} \). It follows that the functor \( G \) is conservative (see Corollary 4.2.3.2 for a stronger version of this statement). Consequently, to show that \( v \) is an equivalence it suffices to show that the induced transformation \( \alpha : G \circ F \circ G \to G \) is an equivalence of functors. We now observe that \( u \) provides a right inverse to this \( \alpha \). Since \( u \) is an equivalence, we conclude also that \( \alpha \) is an equivalence.

Let \( \mathcal{C} \) be a monoidal \( \infty \)-category. Assume that \( \mathcal{C} \) admits countable coproducts and that the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves countable coproducts separately in each variable, so that the forgetful functor \( \text{Alg}(\mathcal{C}) \to \mathcal{C} \) admits a left adjoint \( \text{Fr} : \mathcal{C} \to \text{Alg}(\mathcal{C}) \) given by

\[
\text{Fr}(C) = \Pi_{n \geq 0} C^{\otimes n}
\]

(see Proposition 4.1.1.14). Suppose we are given a map \( \epsilon_0 : C \to 1 \), where \( 1 \) denotes the unit object of \( \mathcal{C} \). Then \( \epsilon_0 \) induces a morphism of algebra objects \( \epsilon : \text{Fr}(C) \to 1 \). Using this map, we can regard \( 1 \) as a left \( \text{Fr}(C) \)-module and \( \epsilon \) as a morphism of left \( \text{Fr}(C) \)-modules. Let \( \text{Fr}(C) \otimes C \) denote the free left \( \text{Fr}(C) \)-module generated by the object \( C \in \mathcal{C} \). The tautological map \( C \to \text{Fr}(C) \) extends to a map of left \( \text{Fr}(C) \)-modules \( m : \text{Fr}(C) \otimes C \to \text{Fr}(C) \). There is another morphism \( \tau_0 : \text{Fr}(C) \otimes C \to \text{Fr}(C) \) obtained by tensoring the map \( \epsilon_0 : C \to 1 \) with the identity map on \( \text{Fr}(C) \). Note that the composite maps

\[
\text{Fr}(C) \otimes C \xrightarrow{\tau_0} \text{Fr}(C) \xrightarrow{\epsilon} 1
\]

\[
\text{Fr}(C) \otimes C \xrightarrow{m} \text{Fr}(C) \xrightarrow{\epsilon} 1
\]

are canonically homotopic to one another (as maps of left \( \text{Fr}(C) \)-modules), since they both correspond to the morphism \( \epsilon_0 \) under the homotopy equivalence

\[
\text{Map}_{\text{LMod}_{\text{Fr}(C)}(\mathcal{C})}(\text{Fr}(C) \otimes C, 1) \simeq \text{Map}_{\mathcal{C}}(C, 1).
\]

We therefore obtain a commutative diagram

\[
\text{Fr}(C) \otimes C \xrightarrow{m} \text{Fr}(C) \xrightarrow{\epsilon} 1
\]

in the \( \infty \)-category \( \text{LMod}_{\text{Fr}(C)}(\mathcal{C}) \).

**Proposition 4.2.4.10.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category which admits countable coproducts for which the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves countable coproducts separately in each variable. Suppose we are given an object \( C \in \mathcal{C} \) together with a morphism \( \epsilon_0 : C \to 1 \). Then the above construction determines a colimit diagram

\[
\text{Fr}(C) \otimes C \xrightarrow{m} \text{Fr}(C) \xrightarrow{\epsilon} 1
\]

in the \( \infty \)-category \( \text{LMod}_{\text{Fr}(C)}(\mathcal{C}) \). In other words, we can identify \( 1 \) with the coequalizer of the pair of morphisms \( m, \tau_0 : \text{Fr}(C) \otimes C \to \text{Fr}(C) \).
Proof. By virtue of Corollary 4.2.3.5, it will suffice to show that for every object \( D \in \mathcal{C} \), the induced diagram

\[
D \otimes \text{Fr}(C) \otimes C \xrightarrow{id_D \otimes \tau_0} D \otimes \text{Fr}(C) \xrightarrow{\epsilon} D
\]

is a coequalizer diagram in \( \mathcal{C} \). For this, it will suffice to prove the following:

(a) The pair of morphisms

\[(id_D \otimes m), (id_D \otimes \tau_0) : D \otimes \text{Fr}(C) \otimes C \to D \otimes \text{Fr}(C)\]

admit a coequalizer \( E \) in \( \mathcal{C} \).

(b) The composite map

\[ D \simeq D \otimes 1 \to D \otimes \text{Fr}(C) \to E \]

is an equivalence in \( \mathcal{C} \).

Let \( \mathcal{J} \) denote the category whose objects are nonnegative integers and whose morphisms are as indicated in the diagram

\[
\cdots \leftarrow 5 \leftarrow 4 \leftarrow 3 \leftarrow 2 \leftarrow 1 \rightarrow 0.
\]

Let \( \mathcal{J} \) denote the category containing two objects \( x \) and \( y \), with morphism sets given by

\[
\text{Hom}_{\mathcal{J}}(x, x) = \{\text{id}_x\} \quad \text{Hom}_{\mathcal{J}}(y, y) = \{\text{id}_y\}.
\]

\[
\text{Hom}_{\mathcal{J}}(x, y) = \{f, g\} \quad \text{Hom}_{\mathcal{J}}(y, x) = \emptyset.
\]

We define a functor \( \pi : \mathcal{J} \to \mathcal{J} \), given on objects by the formula

\[
\pi(n) = \begin{cases} 
  x & \text{if } n \text{ is odd} \\
  y & \text{if } n \text{ is even},
\end{cases}
\]

which carries morphisms of the form \((2k + 1) \to 2k\) to \(f\) and morphisms of the form \((2k - 1) \to 2k\) to \(g\).

There is a functor \( q : N(\mathcal{J}) \to \mathcal{C} \) given by the diagram

\[
\cdots \to D \otimes C \otimes C \xrightarrow{id} D \otimes C \otimes C \xrightarrow{id \otimes \tau_0} D \otimes C \xrightarrow{id} D \otimes C \xrightarrow{id \otimes \tau_0} D.
\]

Using the assumption that \( \mathcal{C} \) admits countable coproducts, we see that \( q \) admits a left Kan extension \( q' \) along the functor \( \pi : N(\mathcal{J}) \to N(\mathcal{J}) \). Unwinding the definitions, we see that the map \( q' : N(\mathcal{J}) \to \mathcal{C} \) classifies the diagram

\[(id_D \otimes m), (id_D \otimes \tau_0) : D \otimes \text{Fr}(C) \otimes C \to D \otimes \text{Fr}(C)\].

We are therefore reduced to proving the following versions of (a) and (b):

(a') The diagram \( q : N(\mathcal{J}) \to \mathcal{C} \) admits a colimit in \( \mathcal{C} \).

(b') The canonical map \( D = q(0) \to \lim_{\mathcal{J}} q \) is an equivalence in \( \mathcal{C} \).

For each \( n \geq 0 \), let \( \mathcal{J}(n) \) denote the full subcategory of \( \mathcal{J} \) consisting of nonnegative integers \( \leq n \). It follows immediately from the definitions that \( q|_{\mathcal{J}(n)} \) is a left Kan extension of \( q|_{\mathcal{J}(n-1)} \) when \( n \) is even, and that the inclusions \( N(\mathcal{J}(n-1)) \hookrightarrow N(\mathcal{J}(n)) \) are left cofinal when \( n \) is odd. It follows by induction on \( n \) that each of the diagrams \( q|_{\mathcal{J}(n)} \) admits a colimit in \( \mathcal{C} \) and that the maps in the diagram

\[
\lim_{n} q|_{\mathcal{J}(0)} \to \lim_{n} q|_{\mathcal{J}(1)} \to \lim_{n} q|_{\mathcal{J}(2)} \to \cdots
\]

are equivalences. In particular, the colimit \( \lim_{n} q|_{\mathcal{J}(n)} \) exists in \( \mathcal{C} \) and is equivalent to \( \lim_{n} q|_{\mathcal{J}(0)} \simeq q(0) = D \), which proves (a') and (b').

\[ \square \]
4.3 Bimodules

Let \( \mathcal{C} \) be a monoidal category. Given a pair of associative algebra objects \( A, B \in \text{Alg}(\mathcal{C}) \), one can define a category \( _A\text{BMod}_B(\mathcal{C}) \) of \( A-B \) bimodule objects of \( \mathcal{C} \). By definition, an \( A-B \) bimodule is an object \( M \in \mathcal{C} \) equipped with multiplication maps \( m : A \otimes M \to M \) and \( m' : M \otimes B \to M \) with the following properties:

(i) The multiplication \( m \) determines a left action of \( A \) on \( M \). That is, if \( m_A : A \otimes A \to A \) and \( e : 1 \to A \) denote the multiplication and unit maps of \( A \), then the diagrams

\[
\begin{array}{ccc}
A \otimes A \otimes M & \xrightarrow{m_A \otimes \text{id}} & A \otimes M \\
\downarrow & & \downarrow \\
A \otimes M & \xrightarrow{m} & M \\
\end{array}
\]

and

\[
\begin{array}{ccc}
1 \otimes M & \xrightarrow{e} & A \otimes M \\
\downarrow & & \downarrow \\
M & \xrightarrow{m} & M \\
\end{array}
\]

commute.

(ii) The multiplication \( m' \) determines a right action of \( B \) on \( M \). That is, if \( m_B : B \otimes B \to B \) and \( e' : 1 \to B \) denote the multiplication and unit maps of \( B \), then the diagrams

\[
\begin{array}{ccc}
M \otimes B \otimes B & \xrightarrow{\text{id} \otimes m_B} & M \otimes B \\
\downarrow & & \downarrow \\
M \otimes B & \xrightarrow{m'} & M \\
\end{array}
\]

and

\[
\begin{array}{ccc}
M \otimes 1 & \xrightarrow{e'} & M \otimes B \\
\downarrow & & \downarrow \\
M & \xrightarrow{m'} & M \\
\end{array}
\]

commute.

(iii) The left action of \( A \) on \( M \) commutes with the right action of \( B \) on \( M \): that is, the diagram

\[
\begin{array}{ccc}
A \otimes M \otimes B & \xrightarrow{m \otimes \text{id}} & M \otimes B \\
\downarrow & & \downarrow \\
A \otimes M & \xrightarrow{m'} & M \\
\end{array}
\]

is commutative.

Our goal in this section is to develop an analogous theory of bimodules in the \( \infty \)-categorical setting. We will follow the basic pattern of our approach to left modules in §4.2. We begin in §4.3.1 by introducing an \( \infty \)-operad \( \mathcal{BM}^\circ \) equipped with a pair of inclusions \( \text{Ass}^\circ \hookrightarrow \mathcal{BM}^\circ \hookrightarrow \text{Ass}^\circ \). If \( \mathcal{C}^\circ \) is a symmetric monoidal \( \infty \)-category and \( A, B \in \text{Alg}(\mathcal{C}) \), then we will denote the fiber product \( \{A\} \times_{\text{Alg}(\mathcal{C})} \text{Alg}_{\mathcal{BM}}(\mathcal{C}) \times_{\text{Alg}(\mathcal{C})} \{B\} \) by \( _A\text{BMod}_B(\mathcal{C}) \); we will refer to \( _A\text{BMod}_B(\mathcal{C}) \) as the \( \infty \)-category of \( A-B \)-bimodule objects of \( \mathcal{C} \).

As in the classical case, it is possible to view an \( A-B \)-bimodule object of a symmetric monoidal \( \infty \)-category \( \mathcal{C} \) as an object of \( \mathcal{C} \) which is equipped with a left action of \( A \) and a right action of \( B \) which commute up to coherent homotopy. In §4.3.2, we will make this precise by showing that the \( \infty \)-category of right \( B \)-module objects of \( \mathcal{C} \) is canonically left-tensored over \( \mathcal{C} \), and there is an equivalence of \( \infty \)-categories \( _A\text{BMod}_B(\mathcal{C}) \simeq \text{LMod}_A(\text{RMod}_B(\mathcal{C})) \). In §4.3.3, we will use this equivalence to show that many of the results proven in §4.2 for left modules (such as the existence of limits and colimits and the structure of free modules) admit straightforward generalizations to the setting of bimodules.

4.3.1 The \( \infty \)-Operad \( \mathcal{BM}^\circ \)

Our goal in this section is to lay the foundations for an \( \infty \)-categorical theory of bimodules. We begin by formulating the classical theory of bimodules in terms of colored operads.
4.3. **BIMODULES**

**Definition 4.3.1.1.** We define a colored operad $BM$ as follows:

(i) The set of objects of $BM$ has three elements, which we will denote by $a_-$, $a_+$, and $m$.

(ii) Let $\{X_i\}_{i \in I}$ be a finite collection of objects of $BM$ and let $Y$ be another object of $BM$. If $Y = a_-$, then $\text{Mul}_{BM}\{(X_i), Y\}$ is the collection of all linear orderings of $I$ provided that each $X_i = a_-$, and is empty otherwise. If $Y = a_+$, then $\text{Mul}_{BM}\{(X_i), Y\}$ is the collection of all linear orderings of $I$ provided that each $X_i = a_+$, and is empty otherwise. If $Y = m$, then $\text{Mul}_{BM}\{(X_i), Y\}$ is the collection of all linear orderings on $\{i_1 < \cdots < i_n\}$ on the set $I$ with the following property: there is exactly one index $i_k \in I$ such that $X_{i_k} = m$, and $X_{i_j} = a_-$ for $j < k$ and $X_{i_j} = a_+$ for $j > k$.

(iii) The composition law on $BM$ is determined by the composition of linear orderings, as described in Definition 4.1.1.1.

**Remark 4.3.1.2.** Restricting our attention to the pair of objects $a_-, m \in BM$, we obtain a colored suboperad isomorphic to the colored operad $LM$ of Definition 4.2.1.1. Similarly, the pair of objects $a_+, m \in BM$ determine a colored suboperad $RM \subseteq BM$, which underlies the $\infty$-operad $\mathcal{R}M^\circ$ of Variant 4.2.1.36.

**Remark 4.3.1.3.** If $\mathcal{C}$ is a symmetric monoidal category and $F : BM \to \mathcal{C}$ is a map of colored operads, then $F|LM$ determines an associative algebra $A_- = F(a_-)$ in $\mathcal{C}$ and a left $A$-module $M = F(m) \in \mathcal{C}$ (see Remark 4.2.1.3). Similarly, the restriction $F|RM$ determines an associative algebra $A_+ = F(a_+)$ such that $M$ has the structure of a right module over $A_+$. The left action of $A_-$ commutes with the right action of $A_+$, in the sense that the diagram

$$
\begin{array}{ccc}
A_- \otimes M \otimes A_+ & \longrightarrow & A_- \otimes M \\
\downarrow & & \downarrow \\
M \otimes A_+ & \longrightarrow & M
\end{array}
$$

is commutative. To see this, it suffices to observe that both of the composite maps $A_- \otimes M \otimes A_+ \to M$ are given by the unique operation $\phi \in \text{Mul}_{BM}\{(a_-, m, a_+), m\}$. We conclude that $M$ has the structure of an $A_-\!-A_+\!$-bimodule object of $\mathcal{C}$.

Conversely, suppose we are given an object $M \in \mathcal{C}$ equipped with a left action of an associative algebra $A_-$ and a right action of another associative algebra $A_+$. According to Remark 4.2.1.3, the pair $(A_-, M)$ determines a map of colored operads $F_- : LM \to \mathcal{C}$. Similarly, the pair $(A_+, M)$ determines a map of colored operads $F_+ : RM \to \mathcal{C}$. If the diagram $\sigma$ commutes, then $F_-$ and $F_+$ admit a unique amalgamation to a map of colored operads $F : BM \to \mathcal{C}$, which assigns to each operation

$$
\psi \in \text{Mul}_{BM}\{(a_-, \ldots, a_-, m, a_+, \ldots, a_+), m\}
$$

the map

$$
A_- \otimes \cdots \otimes A_- \otimes M \otimes A_+ \otimes \cdots \otimes A_+ \overset{m} \longrightarrow A_- \otimes M \otimes A_+ \overset{a} \longrightarrow M,
$$

where $m$ is given by the multiplication in the algebras $A_-$ and $A_+$ and $a$ is the map appearing in the diagram $\sigma$.

We can summarize the above discussion as follows: giving a map of colored operads $BM \to \mathcal{C}$ is equivalent to giving a pair of associative algebras $A_-, A_+$ in $\mathcal{C}$, together with an $A_-\!-A_+\!$-bimodule $M \in \mathcal{C}$.

**Remark 4.3.1.4.** Every operation $\phi \in \text{Mul}_{BM}\{(X_i), Y\}_{i \in I}$ determines a linear ordering on the set $I$. Passage from $\phi$ to this linear ordering determines a map of colored operads $BM \to \text{Ass}$. This map can be understood as follows: for every symmetric monoidal category $\mathcal{C}$ and every map of colored operads $F : \text{Ass} \to \mathcal{C}$ corresponding to an associative algebra $A \in \mathcal{C}$, the composite map $BM \to \text{Ass} \to \mathcal{C}$ corresponds to $A$, regarded as a bimodule over itself.
**Notation 4.3.1.5.** We let $\mathcal{BM}^\circ$ denote the category obtained by applying Construction 2.1.1.7 to the colored operad $\mathcal{BM}$. We can describe this category concretely as follows:

1. The objects of $\mathcal{BM}^\circ$ are pairs $((n), c_-, c_+)$, where $(n)$ is an object of $\mathcal{Fin}_*$ and $c_-, c_+: (n)^\circ \to [1]$ are maps satisfying $c_-(i) \leq c_+(i)$ for $1 \leq i \leq n$.

2. A morphism from $((n), c_-, c_+)$ to $((n'), c'_-, c'_+)$ in $\mathcal{BM}^\circ$ consists of a morphism $\alpha: (n) \to (n')$ in $\text{Ass}^\circ$ satisfying the following inequality, for each $j \in (n)^\circ$ with $\alpha^{-1}(\{j\}) = \{i_1 < \cdots < i_m\}$:

$$c'_-(j) = c_-(i_1) \leq c_+(i_1) = c_-(i_2) \leq c_+(i_2) = c_-(i_3) \leq \cdots \leq c_+(i_{m-1}) = c_-(i_m) \leq c_+(i_m) = c'_+(j).$$

In terms of this description, the object $a_- \in \mathcal{BM}^\circ$ to the triple $((1), c_-, c_+)$ where $c_-(1) = c_+(1) = 0$. The object $a_+$ corresponds to the triple $((1), c_-, c_+)$ with $c_-(1) = c_+(1) = 1$, and the object $\mathfrak{m}$ corresponds to the triple $((1), c_-, c_+)$ with $c_-(1) = 0$ and $c_+(1) = 1$.

We now introduce the infinite-categorical analogue of Definition 4.3.1.1.

**Definition 4.3.1.6.** We let $\mathcal{BM}^\infty$ denote the nerve of the category $\mathcal{BM}^\circ$. We regard $\mathcal{BM}^\infty$ as an infinite-operad via the forgetful functor $\mathcal{BM}^\circ \to N(\mathcal{Fin}_*)$ (see Example 2.1.1.21).

**Remark 4.3.1.7.** The underlying infinite-category $\mathcal{BM}$ of $\mathcal{BM}^\infty$ is isomorphic to the discrete simplicial set $\Delta^0 \coprod \Delta^0 \coprod \Delta^0$ with three vertices, corresponding to the objects $a_-, \mathfrak{m}, a_+ \in \mathcal{BM}$.

**Remark 4.3.1.8.** The map of colored operads $\mathcal{BM} \to \text{Ass}$ appearing in Remark 4.3.1.4 induces a fibration of infinite-operads $\mathcal{BM}^\infty \to \text{Ass}^\infty$.

**Remark 4.3.1.9.** The inclusions of colored operads $\mathcal{LM} \hookrightarrow \mathcal{BM}$ and $\mathcal{RM} \hookrightarrow \mathcal{BM}$ of Remark 4.3.1.2 determine isomorphisms of $\mathcal{LM}^\circ$ and $\mathcal{RM}^\circ$ onto full subcategories of $\mathcal{BM}^\circ$. We will generally abuse notation and identify $\mathcal{LM}^\circ$ and $\mathcal{RM}^\circ$ with their images in $\mathcal{BM}^\circ$.

**Remark 4.3.1.10.** The inclusions $\mathcal{LM}^\circ, \mathcal{RM}^\circ \hookrightarrow \mathcal{BM}^\circ$ determine two different embeddings of $\text{Ass}^\circ$ into $\mathcal{BM}^\circ$. We will denote the images of these embeddings by $\text{Ass}^\circ_-$ and $\text{Ass}^\circ_+$, respectively. Note that the inclusions $\text{Ass}^\circ_-, \text{Ass}^\circ_+ \subseteq \mathcal{BM}^\circ$ extend to an isomorphism from $\text{Ass}^\circ_+ \boxtimes \text{Ass}^\circ_-$ to the full subcategory of $\mathcal{BM}^\circ$ spanned by objects of the form $((n), c_-, c_+)$ where $c_- = c_+$.

**Notation 4.3.1.11.** Let $\mathcal{C}^\circ \to \mathcal{BM}^\circ$ be a fibration of infinite-operads. We let $\mathcal{C}^\circ_+$ denote the fiber product $\mathcal{C}^\circ_+ \times_{\mathcal{BM}^\circ} \text{Ass}^\circ_+$ (so that $\mathcal{C}^\circ_+$ is a planar infinite-operad, in the sense of Definition 4.1.1.6). We will denote the underlying infinite-category of $\mathcal{C}^\circ_+$ by $\mathcal{C}_+ = \mathcal{C}^\circ_+ \times_{\mathcal{BM}^\infty} \{a_+\}$. Similarly, we define $\mathcal{C}^\circ_- = \mathcal{C}^\circ_\times_{\mathcal{BM}^\circ} \text{Ass}^\circ_-$, $\mathcal{C}_+ = \mathcal{C}^\circ_\times_{\mathcal{BM}^\circ} \{a_+\}$, and $\mathcal{C}_m = \mathcal{C}^\circ_\times_{\mathcal{BM}^\circ} \{\mathfrak{m}\}$. Note that $\mathcal{C}_m$ is an infinite-category which is weakly enriched over the planar infinite-category $\mathcal{C}^\circ_+$ (in the sense of Definition 4.2.1.12). Similarly, $\mathcal{C}_m$ is weakly enriched over the reverse of the planar infinite-category $\mathcal{C}^\circ_+$ (see Remark 4.1.1.8).

**Definition 4.3.1.12.** Let $q: \mathcal{C}^\circ \to \mathcal{BM}^\circ$ be a fibration of infinite-operads and let $M$ denote the fiber $\mathcal{C}_m$. We let $\text{BMod}(\mathcal{M})$ denote the infinite-category $\text{Alg}/\mathcal{B}_M(\mathcal{C})$. We will refer to $\text{BMod}(\mathcal{M})$ as the infinite-category of bimodule objects of $\mathcal{M}$.

Composition with the inclusions $\text{Ass}^\circ_-, \text{Ass}^\circ_+ \subseteq \mathcal{BM}^\circ$ determines a categorical fibration $\text{BMod}(\mathcal{M}) \to \text{Alg}(\mathcal{C}_-) \times \text{Alg}(\mathcal{C}_+)$. Given algebra objects $A \in \text{Alg}(\mathcal{C}_-)$ and $B \in \text{Alg}(\mathcal{C}_+)$, we let $\text{BMod}_B(\mathcal{M})$ denote the fiber product

$$\{A\} \times_{\text{Alg}(\mathcal{C}_-)} \text{BMod}(\mathcal{M}) \times_{\text{Alg}(\mathcal{C}_+)} \{B\}.$$

We will refer to $\text{BMod}_B(\mathcal{M})$ as the infinite-category of $A$-$B$-bimodule objects of $\mathcal{M}$.

**Remark 4.3.1.13.** The notation of Definition 4.3.1.12 is somewhat abusive: the infinite-category $\text{BMod}(\mathcal{M})$ depends not only on the infinite-category $\mathcal{M}$, but also on the fibration of infinite-operads $\mathcal{C}^\circ \to \mathcal{BM}^\circ$ having $\mathcal{M}$ as a fiber.
Remark 4.3.1.14. Let \( q : \mathcal{C}^\otimes \to \mathcal{B}M^\otimes \) be a fibration of \( \infty \)-operads and \( \mathcal{M} = \mathcal{C}_m \). We can think of the objects of \( \text{BMod}(\mathcal{M}) \) as given by triples \((A, B, M)\), where \( A \in \text{Alg}(\mathcal{C}_-), \) \( B \in \text{Alg}(\mathcal{C}_+), \) and \( M \) is an an \( A-B \)-bimodule object of \( \mathcal{M} \).

Example 4.3.1.15. Let \( \mathcal{C}^\otimes \to \mathcal{A}ss^\otimes \) be a planar \( \infty \)-operad. Form the fiber product \( \mathcal{O}^\otimes = \mathcal{C}^\otimes \times_{\mathcal{A}ss^\otimes} \mathcal{B}M^\otimes \) using the fibration of \( \infty \)-operads \( \mathcal{B}M^\otimes \to \mathcal{A}ss^\otimes \) of Remark 4.3.1.8. The fiber \( \mathcal{O}_m \) is isomorphic to \( \mathcal{C}_m \), and the planar \( \infty \)-operads \( \mathcal{O}_m^\otimes \) and \( \mathcal{O}_m^\otimes \) are isomorphic to \( \mathcal{C}_m^\otimes \). We can therefore consider the \( \infty \)-category \( \text{BMod}(\mathcal{C}_m) \simeq \text{Alg}_{BM}/\mathcal{A}ss(\mathcal{C}_m) \) of bimodule objects of \( \mathcal{C}_m \).

Example 4.3.1.16. Let \( \mathcal{C}^\otimes \to \mathcal{A}ss^\otimes \) be a planar \( \infty \)-operad. Composition with the forgetful functor \( \mathcal{B}M^\otimes \to \mathcal{A}ss^\otimes \) of Remark 4.3.1.8 determines a map \( s : \text{Alg}(\mathcal{C}_m) \to \text{BMod}(\mathcal{C}_m) \). This map carries each \( A \in \text{Alg}(\mathcal{C}_m) \) to an object \( s(A) \in \text{BMod}(\mathcal{C}_m) \). We can think of \( s(A) \) as \( A \), regarded as a bimodule over itself. For this reason, we will often not distinguish in notation between \( A \) and \( s(A) \).

Definition 4.3.1.17. Let \( q : \mathcal{C}^\otimes \to \mathcal{B}M^\otimes \) be a fibration of \( \infty \)-operads. We will say that \( q \) exhibits \( \mathcal{C}_m \) as bitensored over \( \mathcal{C}_- \) and \( \mathcal{C}_+ \), if the map \( q \) is a coCartesian fibration.

Remark 4.3.1.18. Let \( \mathcal{C}_m^\otimes \to \mathcal{B}M^\otimes \) be a coCartesian fibration of \( \infty \)-operads. Then \( \mathcal{C}_m^\otimes \) and \( \mathcal{C}_m^\otimes \) are monoidal \( \infty \)-categories. The \( \infty \)-category \( \mathcal{C}_m \) is left-tensored over \( \mathcal{C}_m^\otimes \) (in the sense of Definition 4.2.1.19). Similarly, we can regard \( \mathcal{C}_m \) as right-tensored over \( \mathcal{C}_m^\otimes \) (see Variant 4.2.1.36). Moreover, the left and right actions of \( \mathcal{C}_- \) and \( \mathcal{C}_+ \) on \( \mathcal{C}_m \) commute up to coherent homotopy; in particular, the diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\mathcal{C}_- \times \mathcal{C}_m \times \mathcal{C}_+ & \rightarrow & \mathcal{C}_- \times \mathcal{C}_m \\
\downarrow & & \downarrow \\
\mathcal{C}_m \times \mathcal{C}_+ & \rightarrow & \mathcal{C}_m
\end{array}
\]

commutes up to canonical equivalence.

Remark 4.3.1.19. Suppose that \( q : \mathcal{C}^\otimes \to \mathcal{B}M^\otimes \) is a coCartesian fibration of \( \infty \)-operads, so that \( q \) exhibits \( \mathcal{M} = \mathcal{C}_m \) as bitensored over the monoidal \( \infty \)-categories \( \mathcal{C}_- \) and \( \mathcal{C}_+ \). Let us use the symbol \( \otimes \) to indicate all of the induced functors

\[
\begin{array}{ccc}
\mathcal{C}_- \times \mathcal{C}_- & \rightarrow & \mathcal{C}_- \\
\mathcal{C}_+ \times \mathcal{C}_+ & \rightarrow & \mathcal{C}_+ \\
\mathcal{C}_- \times \mathcal{M} & \rightarrow & \mathcal{M} \\
\mathcal{M} \times \mathcal{C}_+ & \rightarrow & \mathcal{M}
\end{array}
\]

Let \( F : \mathcal{B}M^\otimes \to \mathcal{C}_m^\otimes \) be a bimodule object of \( \mathcal{M} \). Then \( A_- = F(a_-) \) and \( A_+ \in F(a_+) \) are algebra objects of the monoidal \( \infty \)-categories \( \mathcal{C}_- \) and \( \mathcal{C}_+ \), respectively. The object \( M = F(m) \in \mathcal{M} \) is equipped with left and right actions

\[
A_- \otimes M \xrightarrow{a} M \xrightarrow{a'} M \otimes A_+
\]

which exhibit \( M \) as an \( A_-A_+ \)-bimodule object of the homotopy category \( h\mathcal{M} \). In other words, the following diagrams commute up to homotopy:

\[
\begin{array}{ccc}
A_- \otimes A_- \otimes M & \xrightarrow{\text{id}_{A_-} \otimes_{\mathcal{M}} A_-} & A_- \otimes M \\
\downarrow \quad \text{id}_{A_-} \otimes a & & \quad a \downarrow \\
A_- \otimes M & \xrightarrow{a} & M \\
M \otimes A_+ \otimes A_+ & \xrightarrow{\text{id}_{M} \otimes_{\mathcal{M}} A_+} & M \otimes A_+ \\
\downarrow \quad a' \otimes \text{id}_{A_+} & & \quad a' \downarrow \\
M \otimes A_+ & \xrightarrow{a'} & M \\
A_- \otimes M \otimes A_+ & \xrightarrow{\text{id}_{A_-} \otimes_{\mathcal{M}} A_+} & A_- \otimes M \\
\downarrow \quad a \otimes \text{id}_{A_+} & & \quad a \downarrow \\
M \otimes A_+ & \xrightarrow{a} & M.
\end{array}
\]
4.3.2 Bimodules, Left Modules, and Right Modules

Let \( \mathcal{C} \) be a monoidal category containing an object \( M \). If \( A \) and \( B \) are algebra objects of \( \mathcal{C} \), then an \( A \)-\( B \)-bimodule structure on \( M \) is determined by the data of a left action of \( A \) on \( M \) and a right action of \( B \) on \( M \). These data are merely required to satisfy a condition: the commutativity of the diagram \( \sigma : \):

\[
\begin{array}{ccc}
A \otimes M \otimes B & \longrightarrow & A \otimes M \\
\downarrow & & \downarrow \\
M \otimes B & \longrightarrow & M.
\end{array}
\]

In the \( \infty \)-categorical setting, the situation is more subtle. The diagram \( \sigma \) is required to commute up to homotopy, and that homotopy is taken as part of the data defining a bimodule structure on \( M \). Consequently, to describe an \( A \)-\( B \)-bimodule structure on \( M \), it is not sufficient to specify the action of \( A \) on \( M \) and the right action of \( B \) on \( M \) individually. However, we can recover the bimodule structure on \( M \) if we view \( M \) as a right \( B \)-module in the \( \infty \)-category of left \( A \)-modules, rather than the \( \infty \)-category \( \mathcal{C} \) itself. Our goal in this section is to give a precise formulation and proof of this assertion.

We begin by considering a more general situation. Let \( q : \mathcal{C}^\circ \to \mathcal{B} \mathcal{M}^\circ \) be a coCartesian fibration of \( \infty \)-operads, so that \( q \) exhibits the \( \infty \)-category \( \mathcal{C}^m \) as bitensored over the monoidal \( \infty \)-categories \( \mathcal{C}^\circ_\leq \) and \( \mathcal{C}^\circ_\geq \).

In particular, \( \mathcal{C}^m \) is left-tensored over \( \mathcal{C}^\circ \), so that we can consider the \( \infty \)-category \( \text{LMod}(\mathcal{C}^m) \) whose objects are pairs \((A,M)\), where \( B \) is an associative algebra object of \( \mathcal{C}^\circ \) and \( M \) is a left \( A \)-module. Our first goal is to show that \( \text{LMod}(\mathcal{C}^m) \) is right-tensored over \( \mathcal{C}^\circ \). The left action of \( \mathcal{C}^\circ \) can be described informally by the formula \((A,M) \otimes B = (A,M \otimes B)\); in other words, we claim that if \( M \) has the structure of a left \( A \)-module, then the tensor product \( M \otimes B \) inherits a left action of \( A \).

Our first step is to construct a functor \( \text{LMod}(\mathcal{C}^\circ_\leq \times \mathcal{C}^\circ_\geq) \to \mathcal{B} \mathcal{M}^\circ \). In what follows, we adopt the following notational convention: if we are given a subset \( K \subseteq (m)^\circ \times (n)^\circ \), then we implicitly choose an order-preserving isomorphism \( \langle k \rangle^\circ \to K \) (where the ordering on \( K \) is inherited from the lexicographical ordering on \((m)^\circ \times (n)^\circ \)). This gives an isomorphism of finite pointed sets \( K_* = K \cup \{*\} \simeq \langle k \rangle \); we will abuse notation and identify \( K_* \) with the corresponding object of \( \mathcal{F} \text{In}_{**} \).

**Construction 4.3.2.1.** We define a functor \( \text{Pr} : \text{LMod}(\mathcal{C}^\circ_\leq \times \mathcal{C}^\circ_\geq) \to \mathcal{B} \mathcal{M}^\circ \) as defined as follows:

1. Let \((\langle m \rangle, S)\) be an object of \( \text{LM}^\circ \) and \((\langle n \rangle, T)\) an object of \( \text{RM}^\circ \). We let \( \text{Pr}(\langle m \rangle, S) \times (\langle n \rangle, T) = (X_*, c_-, c_+)\), where \( X \) is the finite set \( \langle m \rangle \times T \prod_{S \times T} (S \times (n) \subseteq \langle m \rangle \times (n) \simeq (mn) \).

   and the functions \( c_- \), \( c_+ : X \to [1] \) are given by the formulas

   \[
   c_-(i,j) = \begin{cases} 0 & \text{if } j \in T \\ 1 & \text{if } j \notin T \end{cases} \quad c_+(i,j) = \begin{cases} 0 & \text{if } i \notin S \\ 1 & \text{if } i \in S. \end{cases}
   \]

2. Let \( \alpha : \langle m \rangle \to \langle m' \rangle \) be a morphism in \( \text{LM}^\circ \) and \( \beta : \langle n \rangle \to \langle n' \rangle \) a morphism in \( \text{RM}^\circ \). Let \( (X_*, c_-, c_+) = \text{Pr}(\langle m \rangle, S) \times (\langle n \rangle, T) \) and \( (X_*', c'_-, c'_+) = \text{Pr}(\langle m' \rangle, S') \times (\langle n' \rangle, T') \) be defined as above. Then \( \text{Pr}(\alpha, \beta) : (X_*, c_-, c_+) \to (X_*', c'_-, c'_+) \) is the unique morphism in \( \mathcal{B} \mathcal{M}^\circ \) lying over the map \( \gamma : x_* \to x'_* \) which is described as follows:

   (i) If \((i,j) \in X \subseteq (m)^\circ \times (n)^\circ \), then

   \[
   \gamma(i,j) = \begin{cases} (\alpha(i), \beta(j)) & \text{if } \alpha(i) \in (m')^\circ, \beta(j) \in (n')^\circ \\ * & \text{otherwise}. \end{cases}
   \]
(ii) Let \( i' \in \langle n' \rangle^\circ - S \) and \( j' \in T' \), so that \( j' = \beta(j) \) for a unique element \( j \in T \). Then the linear ordering on \( \gamma^{-1}\{(i', j')\} = \alpha^{-1}\{i'\} \times \{j\} \) is determined by the map \( \alpha \) in \( \text{Ass}^\circ \).

(iii) Let \( i' \in S \) and \( j' \in \langle n' \rangle^\circ - T' \), so that \( i' = \alpha(i) \) for a unique element \( i \in S \). Then the linear ordering on \( \gamma^{-1}\{(i', j')\} = \{i\} \times \beta^{-1}\{j'\} \) is determined by the map \( \beta \) in \( \text{Ass}^\circ \).

(iv) Let \( i' \in S' \) and \( j' \in T' \), so that \( i' = \alpha(i) \) and \( j' = \beta(j) \) for unique elements \( i \in S \), \( j \in T \). Then \( \gamma^{-1}\{(i', j')\} = (\alpha^{-1}\{i'\} \times \{j\}) \coprod_{\{i,j\}} (\{i\} \times \beta^{-1}\{j'\}) \). We endow \( \gamma^{-1}\{(i', j')\} \) with the unique linear ordering which is compatible with the linear orders on \( \alpha^{-1}\{i'\} \) and \( \beta^{-1}\{j'\} \) determined by \( \alpha \) and \( \beta \) (so that \( x \leq y \) for \( x \in \alpha^{-1}\{i'\} \times \{j\} \) and \( y \in \{i\} \times \beta^{-1}\{j'\} \), with equality if and only if \( x = y = (i, j) \)).

We will also use \( \text{Pr} \) to denote the induced map of \( \infty \)-categories \( \CM^\circ \times \RM^\circ \to \BM^\circ \).

**Construction 4.3.2.2.** Let \( q : \CM^\circ \to \BM^\circ \) be a fibration of \( \infty \)-operads. We define a map of simplicial sets \( \overline{\text{LMod}}(\CM_m^\circ) \to \RM^\circ \) so that the following universal property is satisfied: for every map of simplicial sets \( K \to \RM^\circ \), there is a canonical bijection

\[
\text{Hom}_{\text{Set}_\Delta} (K, \overline{\text{LMod}}(\CM_m^\circ)) \simeq \text{Hom}_{\text{Set}_\Delta} (\CM^\circ \times K, \CM^\circ).
\]

Let \( \text{LMod}(\CM_m^\circ) \) denote the full simplicial subset of \( \overline{\text{LMod}}(\CM_m^\circ) \) spanned by those vertices which correspond to a vertex \( X \in \RM^\circ \) together with a functor \( F : \CM^\circ \to \CM^\circ \) which carries inert morphisms in \( \CM^\circ \) to inert morphisms in \( \CM^\circ \).

**Remark 4.3.2.3.** As usual, our notation is somewhat abusive: the \( \infty \)-category \( \text{LMod}(\CM_m^\circ) \) depends on the fibration of \( \infty \)-operads \( q : \CM^\circ \to \BM^\circ \), and not just the fiber \( \CM_m \).

**Remark 4.3.2.4.** The composite map

\[
\CM^\circ \times \{m\} \to \CM^\circ \times \RM^\circ \xrightarrow{\text{Pr}} \BM^\circ
\]

coinsides with the inclusion \( \CM^\circ \hookrightarrow \BM^\circ \) of Remark 4.3.1.9. If \( \CM^\circ \to \BM^\circ \) is a fibration of \( \infty \)-operads, we obtain a canonical isomorphism of simplicial sets

\[
\text{LMod}(\CM_m^\circ) \times \RM^\circ \{m\} \simeq \text{LMod}(\CM_m),
\]

where \( \text{LMod}(\CM_m) \) denotes the \( \infty \)-category of left modules associated to the fibration of \( \infty \)-operads

\[
\CM^\circ \times \BM^\circ \CM^\circ \to \CM^\circ.
\]

We can now state our first main result:

**Proposition 4.3.2.5.** Let \( q : \CM^\circ \to \BM^\circ \) be a fibration of \( \infty \)-operads. Then:

1. The induced map map \( p : \text{LMod}(\CM_m^\circ) \to \RM^\circ \) is also a fibration of \( \infty \)-operads.
2. A morphism \( \alpha \) in \( \text{LMod}(\CM_m^\circ) \) is inert if and only if \( p(\alpha) \) is an inert morphism in \( \RM^\circ \) and, for every object \( X \in \CM \), the image \( \alpha(X) \) is an inert morphism in \( \CM^\circ \).
3. Suppose that \( q \) is a coCartesian fibration of \( \infty \)-operads. Then \( p \) is a coCartesian fibration of \( \infty \)-operads.
4. Assume that \( q \) is a coCartesian fibration of \( \infty \)-operads. Then a morphism \( \alpha \in \text{LMod}(\CM_m^\circ) \) is \( p \)-coCartesian if and only if, for every \( X \in \CM \), the image \( \alpha(X) \) is a \( q \)-coCartesian morphism in \( \CM^\circ \).

**Proof.** We will prove (1) and (2); the proofs of (3) and (4) are similar. The proof is essentially the same as that of Proposition 3.2.4.3, despite the fact that \( \text{Pr} : \CM^\circ \times \RM^\circ \to \BM^\circ \) is not a bifunctor of \( \infty \)-operads. We note that the condition on a morphism \( \alpha : M \to M' \in \text{LMod}(\CM_m^\circ) \) appearing in (2) is equivalent to the following apparently stronger condition:
For every inert morphism $\beta : X \to Y$ in $\mathcal{LM}^\otimes$, the induced map $M(X) \to M'(Y)$ is an inert morphism in $\mathcal{C}^\otimes$.

For every $\infty$-operad $\mathcal{O}^\otimes$, let $\mathcal{P}_\mathcal{O}$ be the categorical pattern appearing in the proof of Proposition 3.2.4.3. Using the functor $\text{Pr}$, we see that the construction $\hat{\mathbf{X}} \mapsto \mathcal{LM}^{\otimes, \Delta} \times \hat{\mathbf{X}}$ determines a functor $\theta : (\mathcal{Set}_\Delta^+) / \mathcal{C}_{\mathcal{CL}} \to (\mathcal{Set}_\Delta^+) / \mathcal{C}_{\mathcal{CR}}$. Let $G$ denote a right adjoint to $\theta$. Assertions (1) and (2) are equivalent to the requirement that $G$ preserves fibrant objects. We will complete the proof by showing that $\theta$ is a left Quillen functor. Since $\mathcal{LM}^{\otimes, \Delta} \in (\mathcal{Set}_\Delta^+) / \mathcal{C}_{\mathcal{CL}}$ is cofibrant, it will suffice to show that the product functor

$$(\mathcal{Set}_\Delta^+) / \mathcal{C}_{\mathcal{CL}} \times (\mathcal{Set}_\Delta^+) / \mathcal{C}_{\mathcal{CR}} \to (\mathcal{Set}_\Delta^+) / \mathcal{C}_{\mathcal{CM}}$$

determined by $\text{Pr}$ is a left Quillen bifunctor. This follows immediately from Remark B.2.5 and Proposition B.2.9.

Let $q : \mathcal{C}^\otimes \to \mathcal{B}M^\otimes$ be a fibration of $\infty$-operads. We note that the inclusion $\{m\} \hookrightarrow \mathcal{LM}^\otimes$ determines a forgetful functor $\theta : \mathcal{LM}(\mathcal{C}_m)^\otimes \to \mathcal{C}^\otimes \times_{\mathcal{B}M^\otimes} \mathcal{RM}^\otimes$. Using Proposition 4.3.2.5, we see that $\theta$ is a fibration of $\infty$-operads. Moreover, if $q$ is a coCartesian fibration of $\infty$-operads, then $\theta$ is an $\mathcal{RM}$-monoidal functor.

**Proposition 4.3.2.6.** Let $q : \mathcal{C}^\otimes \to \mathcal{B}M^\otimes$ be a fibration of $\infty$-operads. Then the forgetful functor

$$\mathcal{LM}(\mathcal{C}_m)^\otimes \to \mathcal{C}^\otimes \times_{\mathcal{B}M^\otimes} \mathcal{RM}^\otimes$$

induces a trivial Kan fibration of planar $\infty$-operads

$$\mathcal{LM}(\mathcal{C}_m)^\otimes / q \to \mathcal{C}^\otimes / q.$$

**Proof.** Let $\mathcal{X}$ denote the full subcategory of $\mathcal{Fun}(\mathcal{LM}^\otimes, \mathcal{B}M^\otimes)$ spanned by those functors of the form $X \mapsto \text{Pr}(X, Y)$, where $Y \in \text{Ass}_\mathcal{C}^\otimes \subseteq \mathcal{RM}^\otimes$. Let $\mathcal{X}'$ denote the full subcategory of $\mathcal{Fun}(\mathcal{LM}^\otimes, \mathcal{C}^\otimes)$ spanned by those functors $F : \mathcal{LM}^\otimes \to \mathcal{C}^\otimes$ such that $q \circ F \in \mathcal{X}$ and $F$ carries inert morphisms in $\mathcal{LM}^\otimes$ to inert morphisms in $\mathcal{C}^\otimes$. There is an evident pullback diagram

$$\begin{array}{ccc}
\mathcal{LM}(\mathcal{C}_m)^\otimes / q & \to & \mathcal{X}'
\downarrow & \downarrow \theta
\mathcal{C}^\otimes / q & \to & \mathcal{X} \times \mathcal{Fun}(\{m\}, \mathcal{B}M^\otimes) \mathcal{Fun}(\{m\}, \mathcal{C}^\otimes).
\end{array}$$

It will therefore suffice to show that the map $\theta$ is a trivial Kan fibration.

Let $\mathcal{LM}_0^\otimes$ denote the full subcategory of $\mathcal{LM}^\otimes$ spanned by those objects of the form $\langle (n), S \rangle$, where $S = \langle \mathcal{O} \rangle$. Then $\mathcal{LM}_0^\otimes$ is isomorphic to the trivial $\infty$-operad $\mathcal{Triv}^\otimes$ of Example 2.1.1.20. Let $\mathcal{Z}'$ denote the full subcategory of $\mathcal{Fun}(\mathcal{LM}_0^\otimes, \mathcal{C}^\otimes)$ spanned by those functors which carry each morphism in $\mathcal{LM}_0^\otimes$ to an inert morphism in $\mathcal{C}^\otimes$. The map $\theta$ factors as a composition

$$\mathcal{X}' \overset{\theta'}\to \mathcal{X} \times \mathcal{Fun}(\mathcal{LM}_0^\otimes, \mathcal{B}M^\otimes) \mathcal{Z}' \overset{\theta''}\to \mathcal{X} \times \mathcal{Fun}(\{m\}, \mathcal{B}M^\otimes) \mathcal{Fun}(\{m\}, \mathcal{C}^\otimes).$$

We will complete the proof by showing that $\theta'$ and $\theta''$ are trivial Kan fibrations.

We first show that $\theta'$ is a trivial Kan fibration. In view of Proposition T.4.3.2.15, it will suffice to show the following:

(a) Let $Y \in \text{Ass}_\mathcal{C}^\otimes$ and let $f : \mathcal{LM}^\otimes \to \mathcal{B}M^\otimes$ be given by the formula $f(X) = \text{Pr}(X, Y)$. Suppose that $f|_{\mathcal{LM}_0^\otimes}$ lifts to an object $\bar{f} \in \mathcal{Z}'$. Then there exists a dotted arrow as indicated in the diagram

$$\begin{array}{ccc}
\mathcal{LM}_0^\otimes & \overset{\bar{f}}\to & \mathcal{C}^\otimes
\downarrow & \downarrow q
\mathcal{LM}^\otimes & \overset{f}\to & \mathcal{B}M^\otimes.
\end{array}$$

such that $F$ is a $q$-left Kan extension of $\bar{f}$. 

(b) Given a commutative diagram as above, $F$ is a $q$-left Kan extension of $\mathcal{F}$ if and only if $F$ carries inert morphisms in $\mathcal{LM}^\otimes$ to inert morphisms in $\mathcal{C}^\otimes$.

Note that the inclusion $\mathcal{LM}_0^\otimes \to \mathcal{LM}^\otimes$ admits a right adjoint $r$, which carries an object $(m, S) \in \mathcal{LM}^\otimes$ to the pair $(S, S)$ (where we abuse notation by identify the finite pointed set $S = S \cup \{\star\}$ with an object of $\text{Fin}_\ast$). For each object $X \in \mathcal{LM}^\otimes$, our assumption that $Y \in \text{Ass}_+^\otimes$ guarantees that the functor $f$ carries the counit map $\alpha_X : r(X) \to X$ to degenerate edge of $\mathcal{BM}^\otimes$. To prove (a), we take $F = \mathcal{F} \circ r$. Moreover, we obtain the following version of (b):

(b') Given a commutative diagram as in (a), the functor $F$ is a $q$-left Kan extension of $\mathcal{F}$ if and only if, for each $X \in \mathcal{LM}^\otimes$, the induced map $F(r(X)) \to F(X)$ is an equivalence in $\mathcal{C}^\otimes$.

We now prove (b). Assume we are given a commutative diagram as in (a). Suppose first that $F$ carries inert morphisms in $\mathcal{LM}^\otimes$ to inert morphisms in $\mathcal{C}^\otimes$. Let $X \in \mathcal{LM}^\otimes$, and note that there exists a commutative diagram

$$
\begin{array}{ccc}
X & \xrightarrow{v_X} & Z \\
v_X & \downarrow & \downarrow \\
r(X) & \xrightarrow{\beta} & r(X).
\end{array}
$$

Then $F(\beta)$ is an inert morphism in the fiber $\mathcal{C}^\otimes_{(r(X))}$ and therefore an equivalence. Since $F(v_X)$ is a right inverse to $F(\beta)$, we conclude that $F(v_X)$ is an equivalence. Using (b'), we conclude that $F$ is a $q$-left Kan extension of $\mathcal{F}$. Conversely, suppose that $F$ is a $q$-left Kan extension of $\mathcal{F}$, and let $\alpha : X \to Y$ be an inert morphism in $\mathcal{LM}^\otimes$. We have a commutative diagram

$$
\begin{array}{ccc}
r(X) & \xrightarrow{v_X} & X \\
\downarrow & & \downarrow \\
r(Y) & \xrightarrow{v_Y} & Y
\end{array}
$$

in $\mathcal{LM}^\otimes$. Using (b'), we see that $F(v_X)$ and $F(v_Y)$ are equivalences in $\mathcal{C}^\otimes$. Our assumption that $\mathcal{F} \in \mathcal{Z}'$ guarantees that $F(r(\alpha))$ is inert, so that $F(\alpha)$ is inert as desired. This completes the proof that $\theta'$ is a trivial Kan fibration.

Let $\mathcal{Z}$ denote the full subcategory of $\text{Fun}(\mathcal{LM}_0^\otimes, \mathcal{BM}^\otimes)$ spanned by those functors of the form $X \mapsto \text{Pr}(X, Y)$ for some $Y \in \text{Ass}_+^\otimes$. We observe that $\theta''$ is a pullback of the forgetful functor

$$
\psi : \mathcal{Z}' \to \mathcal{Z} \times_{\text{Fun}(\{m\}, \mathcal{BM}^\otimes)} \text{Fun}(\{m\}, \mathcal{RM}^\otimes).
$$

It will therefore suffice to show that $\psi$ is a trivial Kan fibration. We proceed as in Example 2.1.3.5. Using Proposition T.4.3.2.15, we are reduced to proving the following:

(c) Let $Y \in \text{Ass}_+^\otimes$ and let $g : \mathcal{LM}_0^\otimes \to \mathcal{BM}^\otimes$ be given by the formula $g(X) = \text{Pr}(X, Y)$. Let $Y$ be an object of the fiber $\mathcal{C}^\otimes_{Y}$. Then there exists a dotted arrow as indicated in the diagram

$$
\begin{array}{ccc}
\{m\} & \xrightarrow{\mathcal{F}} & \mathcal{C}^\otimes \\
\downarrow & & \downarrow \\
\mathcal{LM}_0^\otimes & \xrightarrow{g} & \mathcal{BM}^\otimes
\end{array}
$$

such that $G$ is a $q$-right Kan extension of $G|\{m\}$.
(d) Given a commutative diagram as above, \( G \) is a \( q \)-right Kan extension of \( G\{\{m\} \) if and only if carries inert morphisms in \( C M^\circ \) to inert morphisms in \( C \).

Assertion (c) follows immediately from Remark 2.1.2.11, since \( q \) is a fibration of \( \infty \)-operads. The characterization of assertion (d) follows from Remark 2.1.2.9 (applied to \( G \), regarded as a section of the \( \infty \)-operad fibration \( C^\circ \times B M^\circ \)). \( \Box \)

The main result of this section can be stated as follows:

**Theorem 4.3.2.7.** Let \( q : C^\circ \to B M^\circ \) be a fibration of \( \infty \)-operads. Then composition with the functor \( \Pr : LM^\circ \times RM^\circ \to BM^\circ \) induces an equivalence of \( \infty \)-categories

\[
\theta : B Mod(C) \to R Mod(L Mod(C)).
\]

**Proof.** Let \( X \) denote the fiber product \( C^\circ \times B M^\circ \times C M^\circ \times R M^\circ \). The canonical map

\[
X \to LM^\circ \times RM^\circ \to N(Fin_+) \times R M^\circ
\]

exhibits \( X \) as a \( \infty \)-family of \( \infty \)-operads. Let \( \gamma : N(\Delta)^{op} \times \Delta^1 \to LM^\circ \) be as in Remark 4.2.2.8 and let \( M \) be the collection of morphisms \( f \) in \( N(\Delta)^{op} \times \Delta^1 \) such that \( \gamma(f) \) is an inert morphism in \( LM^\circ \). Let \( \gamma^\circ \) denote the full subcategory of

\[
Fun_{LM^\circ}(N(\Delta)^{op} \times \Delta^1, X) \times Fun_{(N(\Delta)^{op} \times \Delta^1)^{op} \times R M^\circ} R M^\circ
\]

spanned by those pairs \( (F, Y) \), where \( Y \in R M^\circ \) and \( F : N(\Delta)^{op} \times \Delta^1 \to X \) is a functor which carries every morphism in \( M \) to an inert morphism in the \( \infty \)-operad \( X \). It follows from Proposition 4.2.2.12 that composition with \( \gamma \) induces an equivalence of \( \infty \)-categories \( L Mod(C) \to \gamma \). In particular, the categorical fibration \( p : \gamma^\circ \to R M^\circ \) is a fibration of \( \infty \)-operads. Note also that a morphism in \( \gamma^\circ \) is inert if and only if its image in \( R M^\circ \) is inert and the corresponding functor \( N(\Delta)^{op} \times \Delta^1 \to X \) carries every morphism in

\[
M \times \text{Hom}_{\Delta}(\Delta^1, \Delta^1) \subseteq \text{Hom}_{\Delta}(\Delta^1, N(\Delta)^{op} \times \Delta^1 \times \Delta^1)
\]

to an inert morphism in \( X \).

Reversing the order of linearly ordered sets determines isomorphisms

\[
\text{rev} : N(\Delta)^{op} \to N(\Delta)^{op} \quad \text{rev} : LM^\circ \to LM^\circ.
\]

Let \( \gamma' : N(\Delta)^{op} \times \Delta^1 \to R M^\circ \) be defined so that the diagram

\[
\begin{array}{ccc}
N(\Delta)^{op} \times \Delta^1 & \xrightarrow{\gamma'} & R M^\circ \\
\downarrow \text{rev \times id} & & \downarrow \text{rev} \\
N(\Delta)^{op} \times \Delta^1 & \xrightarrow{\gamma} & LM^\circ
\end{array}
\]

commutes, and let \( M' \) be the collection of all morphisms \( f \) in \( N(\Delta)^{op} \times \Delta^1 \) such that \( \gamma'(f) \) is an inert morphism in \( R M^\circ \). Let \( Z \) be the full subcategory of \( \text{Fun}_{R M^\circ}(N(\Delta)^{op} \times \Delta^1, \gamma^\circ) \) spanned by those functors which carry every morphism in \( M' \) to an inert morphism in \( \gamma \). The analogue of Proposition 4.2.2.12 for right modules implies that \( \gamma' \) induces an equivalence of \( \infty \)-categories \( \theta'' : R Mod(\gamma) \to Z \).

Let \( \phi : B Mod(C) \to Z \) be the composite functor

\[
B Mod(C) \xrightarrow{\theta} R Mod(L Mod(C)) \xrightarrow{\theta'} R Mod(\gamma) \xrightarrow{\theta''} Z.
\]

The above argument shows that \( \theta' \) is an equivalence of \( \infty \)-categories, and the analogue of Proposition 4.2.2.11 for right modules implies that \( \theta'' \) is an equivalence of \( \infty \)-categories. To complete the proof, it will suffice to show that \( \phi \) is an equivalence of \( \infty \)-categories.
Let $J_1$ denote the category $\Delta^{op} \times \Delta^{op} \times [1] \times [1]$. Let $\psi: J_1 \to \mathcal{B} \mathcal{M}^\circ$ be the composite functor

$$J_1 \overset{\gamma \times \gamma'}{\rightarrow} \mathcal{L} \mathcal{M}^\circ \times \mathcal{R} \mathcal{M}^\circ \overset{\mathcal{P}_r}{\rightarrow} \mathcal{B} \mathcal{M}^\circ.$$ 

Unwinding the definitions, we see that $\mathcal{Z}$ can be identified with the full subcategory of $\text{Fun}_{\mathcal{B} \mathcal{M}^\circ}(N(J_1), \mathcal{C}^\circ)$ spanned by those functors which carry every morphism belonging to $M \times M'$ to an inert morphism in $\mathcal{C}^\circ$.

Let $J$ denote the categorical mapping cylinder of the functor $\psi: J_1 \to \mathcal{B} \mathcal{M}^\circ$. More precisely, we define $J$ as follows:

1. An object of $J$ is either an object of $\mathcal{B} \mathcal{M}^\circ$ or an object of $J_1$.
2. Morphisms in $J$ are given by the formulas

$$\text{Hom}_J(X, Y) = \begin{cases} 
\text{Hom}_{\mathcal{B} \mathcal{M}^\circ}(X, Y) & \text{if } X, Y \in \mathcal{B} \mathcal{M}^\circ \\
\text{Hom}_{J_1}(X, Y) & \text{if } X, Y \in J_1 \\
\text{Hom}_{\mathcal{B} \mathcal{M}^\circ}(X, \psi(Y)) & \text{if } X \in \mathcal{B} \mathcal{M}^\circ, Y \in J_1 \\
\emptyset & \text{if } X \in J_1, Y \in \mathcal{B} \mathcal{M}^\circ.
\end{cases}$$

The functor $\psi$ extends to a retraction of $J$ onto the subcategory $\mathcal{B} \mathcal{M}^\circ \subseteq J$. We let $Z'$ denote the full subcategory of $\text{Fun}_{\mathcal{B} \mathcal{M}^\circ}(N(J), \mathcal{C}^\circ)$ spanned by those functors $f: N(J) \to \mathcal{C}^\circ$ which satisfy the following conditions:

1. For every object $X \in J_0$, the canonical map $f(\psi(X)) \to f(X)$ is an equivalence in $\mathcal{C}^\circ$.
2. The restriction $f|_f^{\mathcal{B} \mathcal{M}^\circ}$ is carries inert morphisms in $\mathcal{B} \mathcal{M}^\circ$ to inert morphisms in $\mathcal{C}^\circ$.

Note that conditions (i) and (ii) immediately imply the following:

3. The restriction $f|_N(J_1)$ carries morphisms in $M \times M'$ to inert morphisms in $\mathcal{C}^\circ$.

Condition (i) is equivalent to the requirement that $f$ is a $q$-left Kan extension of $f|_f^{\mathcal{B} \mathcal{M}^\circ}$. Since every functor $f_0 \in \text{Fun}_{\mathcal{B} \mathcal{M}^\circ}(\mathcal{B} \mathcal{M}^\circ, \mathcal{C}^\circ)$ admits a $q$-left Kan extension $f \in \text{Fun}_{\mathcal{B} \mathcal{M}^\circ}(N(J), \mathcal{C}^\circ)$ (given, for example, by $f_0 \circ r$), Proposition T.4.3.2.15 implies that the restriction map $p: Z' \to \text{BMod}(\mathcal{C}_m)$ is a trivial Kan fibration. The map $\phi$ is the composition of a section to $p$ (given by composition with $r$) with the restriction map $p': Z' \to Z$ given by $f \mapsto f|_{J_1}$. It will therefore suffice to show that $p'$ is a trivial Kan fibration. In view of Proposition T.4.3.2.15, this can be deduced from the following pair of assertions:

(a) Every $f_0 \in Z \subseteq \text{Fun}_{\mathcal{B} \mathcal{M}^\circ}(N(J_1), \mathcal{C}^\circ)$ admits a $q$-right Kan extension $f \in \text{Fun}_{\mathcal{B} \mathcal{M}^\circ}(N(J), \mathcal{C}^\circ)$.

(b) Given $f \in \text{Fun}_{\mathcal{N}(\mathcal{J}_{in})}(N(J), \mathcal{C}^\circ)$ satisfying (iii), the functor $f$ is a $q$-right Kan extension of $f|_{N(J_1)}$ if and only if it satisfies conditions (i) and (ii).

We first prove (a). Fix $f_0 \in Z$ and let $((n), c_-, c_+)$ be an object of $\mathcal{B} \mathcal{M}^\circ$. Let $J$ denote the category $J_1 \times \mathcal{J}(\langle (n), c_-, c_+ \rangle)$, and let $g$ denote the composition $N(J) \to N(J_1) \overset{\delta_0}{\to} \mathcal{C}^\circ$, so that $g \circ g$ extends canonically to a map $G: N(J)^\circ \to N(J) \to \mathcal{B} \mathcal{M}^\circ$. According to Lemma T.4.3.2.13, it will suffice to show that $g$ can be extended to a $q$-limit diagram in $\mathcal{C}^\circ$ lying over $G$.

The objects of $J$ can be identified with morphisms $\alpha: ((n), c_-, c_+) \to \psi(X)$ in $\mathcal{B} \mathcal{M}^\circ$, where $X \in J_1$. Let $J_0 \subseteq J$ denote the full subcategory spanned by those objects for which $\alpha$ is inert. The inclusion $J_0 \subseteq J$ has a right adjoint, so that $N(J_0) \to N(J)$ is right cofinal. Consequently, it will suffice to show that $g_0 = g|_{N(J_0)}$ admits a $q$-limit in $\mathcal{C}^\circ$ (compatible with $G$).

Let $J_1$ denote the full subcategory of $J_0$ spanned by the morphism which are either of the form $\rho^1: ((n), c_-, c_+) \to r([0], [0], 0, 0) \simeq \mathcal{M}$ where $c_-(j) = 0 < 1 = c_+(j)$, $\rho^2: ((n), c_-, c_+) \to r([1], [0], 0, 1) = \mathcal{A}$ where $c_-(j) = c_+(j) = 0$, or $\rho^2: ((n), c_-, c_+) \to r([0], [1], 1, 0) = \mathcal{A}$ where $c_-(j) = c_+(j) = 1$. Note that $J_1$ decomposes as a disjoint union of full subcategories $J_1 \simeq \biguplus_{1 \leq j \leq n} J_1(j)$. 

4.3. BIMODULES

389
Let $g_1 = g_0|N(\phi_1)$. We claim that $g_0$ is a $q$-right Kan extension of $g_1$. To prove this, consider an object of $X \in \otimes$, corresponding an morphism $\alpha: ((n), c_-, c_+) \to \psi(X)$ in $B\otimes$. Let $S = \{ j \in \langle n \rangle : \alpha(j) \neq 0 \}$, so that $(\phi_1)_X/\otimes$ decomposes as a disjoint union $\coprod_{j \in S} (\phi_1(j))_X$, where $(\phi_1(j))_X$ denotes the subcategory $\phi_1(j) \times \otimes$, $(\phi_1)_X/\otimes$ has an initial object, given by a morphism $\beta_j: X \to X_j$ in $\phi_1$. If $X = ([m], [n], i, j')$, then

$$\begin{align*}
X_j &= \begin{cases}
([0], [0], 0, 0) & \text{if } c_-(j) = 0 < 1 = c_+(j) \\
([1], [n], 0, 1) & \text{if } c_-(j) = c_+(j) = 0 \\
([m], [1], 1, 0) & \text{if } c_-(j) = c_+(j) = 1.
\end{cases}
\end{align*}$$

In each of these cases, the morphism $\beta_j$ belongs to $M \times M'$, so that $f_0(\beta_j)$ is inert (since $f_0 \in Z$). Since $q$ is a fibration of $\infty$-operads, we conclude that $f_0$ exhibits $f_0(X)$ is a $q$-product of the objects $f_0(X_j)$, and therefore a $q$-limit of $f_0((\phi_1)_X,/\otimes).

Since $g_0$ is a $q$-right Kan extension of $g_0$, it will suffice to show that $g_1$ can be extended to a $q$-limit diagram in $\otimes$ which is compatible with $G$ (Lemma T.4.3.2.7). Each of the $\infty$-categories $\phi_1(j)$ is isomorphic either to $\Delta^0$ to $N(\Delta)^\otimes$, and is in particular weakly contractible. That each restriction $g_1|N(\phi_1(j))$ takes values in the $\infty$-category $\otimes$. (if $c_-(j) = c_+(j) = 0$, $\otimes$ (if $c_-(j) = 0 < 1 = c_+(j)$, or $\otimes$ (if $c_-(j) = c_+(j) = 1$).

The assumption $f_0 \in Z$ guarantees that $g_1|N(\phi_1(j))$ carries each morphism in $\phi_1(j)$ to an equivalence. Since $N(\phi_1(j))$ is weakly contractible, we conclude that $g_1|N(\phi_1(j))$ is equivalent to a constant diagram and admits a $q$-limit $Y_1 \in \otimes$ (Corollary T.4.4.4.10). Since $q$ is a fibration of $\infty$-operads, the objects $Y_1 \in \otimes$ admit a $q$-product in $\otimes$ which is a $q$-limit of $g_1$ compatible with $G$. This completes the proof of (a). Moreover, the proof shows that a functor $f: N(\phi) \to \otimes$ is a $q$-right Kan extension of $f_0$ if and only if it satisfies the following condition:

(i') For every object $((m), c_-, c_+) \in B\otimes$ as above and every object $\alpha: ((m), S) \to X$ belonging to the category $\phi_1$ defined above, the image $f(\alpha)$ is an inert morphism in $\otimes$.

To prove (b), it will suffice to show that if $f \in \text{Fun}_{B\otimes}(N(\phi), \otimes)$ satisfies condition (iii), then it satisfies conditions (i) and (ii) if and only if it satisfies condition (i'). We first prove the “only if” direction. Assume that $f \in Z'$, and let $\alpha: ((m), c_-, c_+) \to X$ be as in (i'). Then $\alpha$ factors as a composition

$$((m), c_-, c_+) \xrightarrow{\alpha'} \psi(X) \xrightarrow{\psi(X)} X,$$

where $\alpha'$ is inert (so that $f(\alpha')$ is inert by (ii)) and $f(\alpha'')$ is an equivalence by virtue of (i).

Suppose now that $f$ satisfies (i') and (iii). We first show that $f$ satisfies (i). Fix an object $X = ([m], [n], i, j) \in \otimes$; we wish to show that $f$ carries the canonical morphism $\alpha: \psi(X) \to X$ to an equivalence in $\otimes$. Let $\psi(X) = ((n), c_-, c_+)$, and let $\phi_1$ be the category defined above, so that $(\phi_1)_X/\otimes \otimes \cong \coprod_{i \leq j \leq n} (\phi_1(j))_X/\otimes$ where each $(\phi_1(j))_X$ contains an initial object given by a morphism $\beta_j: X \to X_j$ in $\phi_1$. Assumption (i') shows that each $f(\beta_j \circ \alpha)$ is inert, and assumption (iii) guarantees that each $f(\beta_j)$ is inert (since $\beta_j \in M \times M'$). It follows that the image of $f(\alpha)$ under the functor $u: \otimes \otimes \psi(X) \to \prod_{1 \leq j \leq n} \otimes_{\psi(X)}$ is an equivalence. Since $q$ is a fibration of $\infty$-operads, the functor $u$ is an equivalence so that $f(\alpha)$ is an equivalence in the $\infty$-category $\otimes_{\psi(X)}$.

It remains to show that $f$ satisfies (ii). For this, it will suffice to show that $f(\alpha)$ is inert whenever $\alpha$ is an inert morphism of $\otimes$ of the form $\alpha: ((m), c_-, c_+) \to ((j), c'_-, c'_+)$. We observe that in this case we can write $((j), c'_-, c'_+) \cong \psi(X)$ so that $\alpha$ determines an object of the category $\phi_1$ defined above. Let $\beta: \psi(X) \to X$ be the evident morphism in $\otimes$. Condition (i') guarantees that $f(\beta \circ \alpha)$ is inert, and condition (i) guarantees that $f(\beta)$ is an equivalence. It follows that $f(\alpha)$ is inert, as desired.

**Corollary 4.3.2.8.** Let $M$ be an $\infty$-category which is bitensored over a pair of monoidal $\infty$-categories $\otimes$ and $\otimes_+$. Let $B \in \text{Alg}(\otimes_+)$, and assume that the unit map $1 \to B$ is an equivalence in $\otimes_+$. Then the forgetful functor

$$\text{BMod}(M) \times_{\text{Alg}(\otimes_+)} \{B\} \to \text{LMod}(M)$$
4.3. BIMODULES

is an equivalence of ∞-categories. In particular, if \( A \in \text{Alg}(\mathcal{C}_-) \), then the forgetful functor

\[
A \text{BMod}_B(M) \to \text{LMod}_A(M)
\]

is an equivalence of ∞-categories.

Proof. Combine Theorem 4.3.2.7, Proposition 4.3.2.6, and Proposition 4.2.4.9.

4.3.3 Limits, Colimits, and Free Bimodules

Let \( \mathcal{C} \) be a monoidal ∞-category and suppose we are given a pair of algebra objects \( A, B \in \text{Alg}(\mathcal{C}) \). In this section, we study the relationship between the ∞-category \( A \text{BMod}_B(\mathcal{C}) \) of \( A-B \)-bimodule objects of \( \mathcal{C} \) and the underlying ∞-category \( \mathcal{C} \). We can summarize our main results as follows:

\( (a) \) Let \( K \) be a simplicial set such that \( \mathcal{C} \) admits \( K \)-indexed limits. Then \( A \text{BMod}_B(\mathcal{C}) \) admits \( K \)-indexed limits, and the forgetful functor \( \text{LMod}_A(M) \to M \) preserves \( K \)-indexed limits (Corollary 4.3.3.3).

\( (b) \) Let \( K \) be a simplicial set such that \( \mathcal{C} \) admits \( K \)-indexed colimits and the tensor product functors \( M \mapsto A \otimes M \) and \( M \mapsto M \otimes B \) preserve \( K \)-indexed colimits. Then \( A \text{BMod}_B(\mathcal{C}) \) admits \( K \)-indexed colimits, and the forgetful functor \( A \text{BMod}_B(\mathcal{C}) \to \mathcal{C} \) preserves \( K \)-indexed colimits (Proposition 4.3.3.9).

\( (c) \) The forgetful functor \( A \text{BMod}_B(\mathcal{C}) \to \mathcal{C} \) admits a left adjoint, given on objects by \( M \mapsto A \otimes M \otimes B \) (Corollary 4.3.3.14).

At the end of this section, we describe an application of \( (c) \), which gives a simple description of bimodule objects in the underlying ∞-category of a monoidal model category (Theorem 4.3.3.17).

The analogues of assertions \( (a), (b), \) and \( (c) \) for left modules were proven in §4.2. It is possible to obtain the results of this section by generalizing the methods of §4.2. We will adopt a different approach, which uses Theorem 4.3.2.7 to reduce questions about bimodule objects to simpler questions about left and right modules. For example, Theorem 4.3.2.7, Proposition 4.2.3.1, and Proposition 4.3.3.15 immediately imply the following:

Proposition 4.3.3.1. Let \( \mathcal{M} \) be an ∞-category which is bitensored over a pair of monoidal ∞-categories \( \mathcal{C}^- \) and \( \mathcal{C}^+ \). Let \( K \) be a simplicial set such that \( \mathcal{M} \) admits \( K \)-indexed limits, and let \( \theta : \text{BMod}(\mathcal{M}) \to \text{Alg}(\mathcal{C}_-) \times \text{Alg}(\mathcal{C}_+) \) be the forgetful functor. Then:

1. For every diagram

\[
\begin{array}{ccc}
K & \to & \text{BMod}(\mathcal{M}) \\
\downarrow & & \downarrow \theta \\
K^\circ & \to & \text{Alg}(\mathcal{C}_-) \times \text{Alg}(\mathcal{C}_+)
\end{array}
\]

there exists a dotted arrow as indicated, which is a \( \theta \)-limit diagram.

2. An arbitrary map \( \overline{\gamma} : K^\circ \to \text{BMod}(\mathcal{M}) \) is a \( \theta \)-limit diagram if and only if the induced map \( K^\circ \to \mathcal{M} \) is a limit diagram.

Corollary 4.3.3.2. Let \( \mathcal{M} \) be an ∞-category which is bitensored over a pair of monoidal ∞-categories \( \mathcal{C}^- \) and \( \mathcal{C}^+ \). Then the forgetful functor \( \theta : \text{BMod}(\mathcal{M}) \to \text{Alg}(\mathcal{C}_-) \times \text{Alg}(\mathcal{C}_+) \) is a Cartesian fibration. A morphism \( f \) in \( \text{BMod}(\mathcal{M}) \) is \( \theta \)-Cartesian if and only if the image of \( f \) in \( \mathcal{M} \) is an equivalence.

Proof. Apply Proposition 4.3.3.1 in the case \( K = \Delta^0 \).

Corollary 4.3.3.3. Let \( \mathcal{M} \) be an ∞-category which is bitensored over a pair of monoidal ∞-categories \( \mathcal{C}^- \) and \( \mathcal{C}^+ \). Let \( A \in \text{Alg}(\mathcal{C}_-) \) and \( B \in \text{Alg}(\mathcal{C}_+) \) be algebra objects, and let \( K \) be a simplicial set such that \( \mathcal{M} \) admits \( K \)-indexed limits. Then:
(1) The \( \infty \)-category \( A \text{BMod}_B(M) \) admits \( K \)-indexed limits.

(2) A map \( p : K^d \to A \text{BMod}_B(M) \) is a limit diagram if and only if the induced map \( K^d \to M \) is a limit diagram.

(3) Given maps of algebra objects \( A \to A', B \to B' \), the induced functor \( A \text{BMod}_B(M) \to A \text{BMod}_B(M) \) preserves \( K \)-indexed limits.

We would next like to discuss an analogue of Proposition 4.3.3.1 for colimits of bimodules. This will require a bit of additional notation.

**Notation 4.3.3.4.** Let \( \tau : \mathcal{C}^\otimes \to \text{Adj}^\otimes \) be the map of \( \infty \)-operads given by the formula \( ((n), S) \mapsto S_\ast \); here we abuse notation by identifying the pointed set \( S_\ast = S \cup \{ \ast \} \) with an object of \( \text{Fin}_\ast \). The functor \( \wedge : \text{Fin}_\ast \times \text{Fin}_\ast \to \text{Fin}_\ast \) of Notation 2.2.5.1 refines to a bifunctor of \( \infty \)-operads

\[
\wedge' : \text{Ass}^\otimes \times \text{Adj}^\otimes \to \text{Ass}^\otimes \simeq \text{Ass}^\otimes \subseteq \text{BM}^\otimes.
\]

Given a fibration of \( \infty \)-operads \( p : \mathcal{C}^\otimes \to \mathcal{B}^\otimes \), we let \( \text{Alg}(\mathcal{C})^\otimes \) denote the fiber product

\[
\mathcal{C}^\otimes \times_{\text{Adj}^\otimes} \text{Alg}/\text{Ass}(\mathcal{C})^\otimes,
\]

where \( \text{Alg}/\text{Ass}(\mathcal{C})^\otimes \to \text{Adj}^\otimes \) is the fibration of \( \infty \)-operads obtained by applying Construction 3.2.4.1 to the map \( \wedge' \). Note that the composition

\[
\text{Ass}^\otimes \times \mathcal{C}^\otimes \xrightarrow{id \times \tau} \text{Ass}^\otimes \times \text{Adj}^\otimes \xrightarrow{\wedge'} \text{BM}^\otimes
\]

coincides with the restriction \( \text{Pr}(\text{Ass}^\otimes \times \mathcal{C}^\otimes) \). Consequently, composition with the inclusion functor \( \text{Ass}^\otimes \times \mathcal{C}^\otimes \to \mathcal{M}^\otimes \times \mathcal{M}^\otimes \) induces a fibration of \( \infty \)-operads \( \text{LMod}(\mathcal{C}^\otimes)_m \to \text{Alg}(\mathcal{C}^\otimes)_m \).

**Remark 4.3.3.5.** Let \( \mathcal{C}^\otimes \to \mathcal{B}^\otimes \) be as in Notation 4.3.3.4. Then \( \text{Alg}(\mathcal{C}^\otimes)^\otimes \simeq \text{Alg}(\mathcal{C}^\otimes) \), and the forgetful functor \( \text{Alg}(\mathcal{C}^\otimes)^\otimes \to \text{Ass}^\otimes \) is a trivial Kan fibration. Example 2.1.3.5 guarantees that evaluation at \( m \) induces an equivalence of \( \infty \)-categories \( \text{RMod}(\text{Alg}(\mathcal{C}^\otimes)) \simeq \text{Alg}(\mathcal{C}^\otimes) \).

**Notation 4.3.3.6.** Let \( \mathcal{C}^\otimes \to \mathcal{B}^\otimes \) be a fibration of \( \infty \)-operads and let \( A \in \text{Alg}(\mathcal{C}^\otimes) \). The composite functor

\[
\text{Ass}^\otimes \times \mathcal{C}^\otimes \xrightarrow{id \times \tau} \text{Ass}^\otimes \times \text{Adj}^\otimes \xrightarrow{\wedge'} \mathcal{C}^\otimes
\]

can be identified with a map \( A' : \mathcal{C}^\otimes \to \text{Alg}(\mathcal{C}^\otimes)^\otimes \), which is a preimage of \( A \) under the trivial Kan fibration \( \text{RMod}(\text{Alg}(\mathcal{C}^\otimes)) \to \text{Alg}(\mathcal{C}^\otimes) \) of Remark 4.3.3.5. We let \( \text{LMod}_A(\mathcal{C}^\otimes)_m \) denote the fiber product

\[
\text{LMod}(\mathcal{C}^\otimes)_m \times_{\text{Alg}(\mathcal{C}^\otimes)^\otimes} \mathcal{C}^\otimes.
\]

**Remark 4.3.3.7.** Let \( p : \mathcal{C}^\otimes \to \mathcal{B}^\otimes \) be a fibration of \( \infty \)-operads and let \( A \in \text{Alg}(\mathcal{C}^\otimes) \). Then the map \( \text{LMod}_A(\mathcal{C}^\otimes)_m \to \mathcal{C}^\otimes \) is a fibration of \( \infty \)-operads, which exhibits the \( \infty \)-category \( \text{LMod}_A(\mathcal{C}^\otimes)_m \simeq \text{LMod}_A(\mathcal{C}^\otimes)_m \) as weakly enriched over the reverse of the planar \( \infty \)-operad \( q : \text{LMod}_A(\mathcal{C}^\otimes)_m \simeq \text{LMod}(\mathcal{C}^\otimes)_m \) (which is equivalent to \( \mathcal{C}_m^\otimes \); see Proposition 4.3.2.6). If \( p \) is a coCartesian fibration of \( \infty \)-operads, then \( q \) is also a coCartesian fibration of \( \infty \)-operads. It follows from Remark 4.3.3.5 that \( \text{RMod}(\text{LMod}_A(\mathcal{C}^\otimes)) \) can be identified with the homotopy fiber of the map

\[
\text{RMod}(\text{LMod}(\mathcal{C}^\otimes)) \to \text{LMod}(\mathcal{C}^\otimes) \to \text{Alg}(\mathcal{C}^\otimes)
\]

over the object \( A \in \text{Alg}(\mathcal{C}^\otimes) \).
follow immediately from the equivalences $\mathcal{K}$ of colimit diagrams if and only if the composite map $\mathcal{K}$ and $\mathcal{C}$ preserves small colimits. Then:

Let $\text{Corollary 4.3.3.10}$. Let $A \in \text{Alg}(\mathcal{E}_-)$ and $B \in \text{Alg}(\mathcal{E}_+)$. We let $R\text{Mod}_B(L\text{Mod}_A(\mathcal{E}_m))$ denote the fiber

$$R\text{Mod}(L\text{Mod}_A(\mathcal{E}_m) \times_{\text{Alg}(\mathcal{E}_+)} \{B\}),$$

where the map $R\text{Mod}(L\text{Mod}_A(\mathcal{E}_m)) \to \text{Alg}(\mathcal{E}_+)$ is the categorical fibration given by composition with the inclusion

$$\{m\} \times \text{Ass} \to \mathcal{L}\text{M} \times \mathcal{R}\text{M}.$$

Since $\text{Alg}(\mathcal{E}_-) \to \text{Ass}$ is a trivial Kan fibration, Proposition 4.3.2.6 guarantees that the categorical fibration $\theta : \text{Alg}(L\text{Mod}_A(\mathcal{E}_m)_A) \to \text{Alg}(\mathcal{E}_+)$ is an equivalence of $\infty$-categories, and therefore a trivial Kan fibration. We may therefore assume that $B = \theta(\mathcal{B})$ for some $\mathcal{B} \in \text{Alg}(L\text{Mod}_A(\mathcal{E}_m)_A)$, and the inclusion

$$R\text{Mod}^\mathcal{B}(L\text{Mod}_A(\mathcal{E}_m)) \to R\text{Mod}_B(L\text{Mod}_A(\mathcal{E}_m))$$

is a categorical equivalence. Combining Remark 4.3.3.7 with Theorem 4.3.2.7, we obtain an equivalence of $\infty$-categories

$$\mathcal{A}B\text{Mod}_B(\mathcal{E}_m) \to R\text{Mod}_B(L\text{Mod}_A(\mathcal{E}_m)).$$

We are now ready to discuss colimits in $\infty$-categories of bimodules.

**Proposition 4.3.3.9.** Let $\mathcal{M}$ be an $\infty$-category which is bitensored over a pair of monoidal $\infty$-categories $\mathcal{E}_-^\otimes$ and $\mathcal{E}_+^\otimes$. Let $A \in \text{Alg}(\mathcal{E}_-)$ and $B \in \text{Alg}(\mathcal{E}_+)$ be algebra objects. Let $K$ be a simplicial set such that $\mathcal{M}$ admits $K$-indexed colimits, and assume that the functors

$$\mathcal{M} \simeq \{A\} \times \mathcal{M} \hookrightarrow \mathcal{E}_- \times \mathcal{M} \to \mathcal{M}$$

$$\mathcal{M} \simeq \mathcal{M} \times \{B\} \hookrightarrow \mathcal{M} \times \mathcal{E}_+ \to \mathcal{M}$$

preserve $K$-indexed colimits. Then:

1. Every diagram $f : K \to \mathcal{A}B\text{Mod}_B(\mathcal{M})$ has a colimit.

2. An arbitrary diagram $\mathcal{F} : K^\circ \to \mathcal{A}B\text{Mod}_B(\mathcal{M})$ is a colimit diagram if and only if it induces a colimit diagram $K^\circ \to \mathcal{M}$.

**Proof.** Applying Corollary 4.2.3.5, we deduce that the $\infty$-category $L\text{Mod}_A(\mathcal{M})$ admits $K$-indexed colimits; moreover, a map $K^\circ \to L\text{Mod}_A(\mathcal{M})$ is a colimit diagram if and only if the induced map $K^\circ \to \mathcal{M}$ is a colimit diagram. Let $\mathcal{B} \in \text{Alg}(L\text{Mod}_A(\mathcal{M})_A)$ be a preimage of $B$ under the trivial Kan fibration $\text{Alg}(L\text{Mod}_A(\mathcal{E}_m)_A) \to \text{Alg}(\mathcal{E}_+)$ of Remark 4.3.3.8. Since the right action of $B$ on $\mathcal{M}$ preserves $K$-indexed colimits, the action of $\mathcal{B}$ on $L\text{Mod}_A(\mathcal{M})$ also preserves $K$-indexed colimits. Applying Corollary 4.2.3.5 again, we deduce that $R\text{Mod}^\mathcal{B}(L\text{Mod}_A(\mathcal{M}))$ admits $K$-indexed colimits; moreover, a map $\mathcal{F} : K^\circ \to R\text{Mod}^\mathcal{B}(L\text{Mod}_A(\mathcal{M}))$ is a colimit diagram if and only if the composite map $K^\circ \to L\text{Mod}_A(\mathcal{M})$ is a colimit diagram (which is equivalent to the requirement that the underlying map $K^\circ \to \mathcal{M}$ is a colimit diagram). Assertions (1) and (2) now follow immediately from the equivalences

$$\mathcal{A}B\text{Mod}_B(\mathcal{M}) \to R\text{Mod}_B(L\text{Mod}_A(\mathcal{M})) \leftarrow R\text{Mod}^\mathcal{B}(L\text{Mod}_A(\mathcal{M}))$$

of Remark 4.3.3.8. \qed

**Corollary 4.3.3.10.** Let $\mathcal{M}$ be an $\infty$-category which is bitensored over a pair of monoidal $\infty$-categories $\mathcal{E}_-^\otimes$ and $\mathcal{E}_+^\otimes$. Assume that $\mathcal{M}$ is presentable and that for every pair of objects $X \in \mathcal{E}_-^\otimes$, $Y \in \mathcal{E}_+^\otimes$, the functors

$$\mathcal{M} \simeq \{X\} \times \mathcal{M} \hookrightarrow \mathcal{E}_- \times \mathcal{M} \to \mathcal{M}$$

$$\mathcal{M} \simeq \mathcal{M} \times \{Y\} \hookrightarrow \mathcal{M} \times \mathcal{E}_+ \to \mathcal{M}$$

preserve small colimits. Then:
(1) For every $A \in \text{Alg}(\mathcal{C}_-)$, $B \in \text{Alg}(\mathcal{C}_+)$, the $\infty$-category $A \text{BMod}_B(M)$ is presentable.

(2) For every $f : A \to A'$ in $\text{Alg}(\mathcal{C}_-)$ and every $g : B \to B'$ in $\text{Alg}(\mathcal{C}_+)$, the associated functor $A \text{BMod}_B(M) \to A' \text{BMod}_B(M)$ preserves small limits and colimits.

(3) The forgetful functor $\theta : B\text{Mod}(M) \to \text{Alg}(\mathcal{C}_-) \times \text{Alg}(\mathcal{C}_+)$ is a presentable fibration (Definition T.5.5.3.2).

Proof. Let $\overline{B}$ be as in Remark 4.3.3.8. Assertion (1) follows from iterated application of Corollary 4.2.3.7, using the equivalences
\[ A \text{BMod}_B(M) \to \text{RMod}_B(L\text{Mod}_A(M)) \leftarrow \text{RMod}_B(L\text{Mod}_A(M)). \]

Assertion (2) follows from Proposition 4.3.3.9 and Corollary 4.3.3.3. Assertion (3) follows from (1) and (2), by virtue of Proposition T.5.5.3.3. \qed

We next use Theorem 4.3.2.7 and the results of §4.2.4 to develop a good theory of free bimodules.

**Definition 4.3.3.11.** Let $\mathcal{M}$ be an $\infty$-category which is bitensored over a pair of monoidal $\infty$-categories $\mathcal{C}_-^\otimes$ and $\mathcal{C}_+^\otimes$. Let $A \in \text{Alg}(\mathcal{C}_-)$, let $B \in \text{Alg}(\mathcal{C}_+)$, and let $M \in A \text{BMod}_B(M)$ be an $A$-$B$-bimodule. We will abuse notation by identifying $M$ with its image in $\mathcal{M}$. We will say that a morphism $M_0 \to M$ in $\mathcal{M}$ exhibits $M$ as the free $A$-$B$-bimodule generated by $M_0$ if the composite map
\[ A \otimes M_0 \otimes B \to A \otimes M \otimes B \to M \]
is an equivalence in $\mathcal{M}$.

Using Remark 4.3.3.8 and Proposition 4.2.4.2, we immediately deduce the following:

**Proposition 4.3.3.12.** Let $\mathcal{M}$ be an $\infty$-category which is bitensored over a pair of monoidal $\infty$-categories $\mathcal{C}_-^\otimes$ and $\mathcal{C}_+^\otimes$. Suppose that we are given objects $A \in \text{Alg}(\mathcal{C}_-)$, $B \in \text{Alg}(\mathcal{C}_+)$, and $M_0 \in \mathcal{M}$. Then:

1. There exists an object $M \in A \text{BMod}_B(M)$ and a morphism $\lambda : M_0 \to M$ in $\mathcal{M}$ which exhibits $M$ as a free $A$-$B$-bimodule generated by $M_0$.

2. Let $M \in A \text{BMod}_B(M)$ and let $\lambda : M_0 \to M$ be a morphism which exhibits $M$ as a free left $A$-module generated by $M_0$. For every $N \in A \text{BMod}_B(M)$, composition with $\lambda$ induces a homotopy equivalence
\[ \text{Map}_{A \text{BMod}_B(M)}(M, N) \to \text{Map}_\mathcal{M}(M_0, N). \]

**Corollary 4.3.3.13.** Let $\mathcal{M}$ be an $\infty$-category which is bitensored over a pair of monoidal $\infty$-categories $\mathcal{C}_-^\otimes$ and $\mathcal{C}_+^\otimes$, and let $A \in \text{Alg}(\mathcal{C}_-)$ and $B \in \text{Alg}(\mathcal{C}_+)$. Then the forgetful functor $A \text{BMod}_B(M) \to \mathcal{M}$ admits a left adjoint, which carries an object $M_0 \in \mathcal{M}$ to a free $A$-$B$-bimodule generated by $M_0$.

**Corollary 4.3.3.14.** Let $\mathcal{M}$ be an $\infty$-category which is bitensored over a pair of monoidal $\infty$-categories $\mathcal{C}_-^\otimes$ and $\mathcal{C}_+^\otimes$. Then the forgetful functor $B\text{Mod}(M) \to \text{Alg}(\mathcal{C}_-) \times \mathcal{M} \times \text{Alg}(\mathcal{C}_+)$ admits a left adjoint, which carries each triple $(A, M_0, B)$ to a free $A$-$B$-bimodule $A \otimes M_0 \otimes B \in A \text{BMod}_B(M)$.

Proof. Combine Proposition 4.3.3.12 with Corollary 4.3.3.1 with Proposition 4.3.3.12. \qed

We conclude this section with a rectification result for bimodule objects in a monoidal model category. Let $\mathcal{A}$ be a simplicial monoidal model category, and $\mathfrak{C} = N(\mathcal{A}^\circ)$ its underlying $\infty$-category. In §4.1.4, we saw that there is often a close relationship between associative algebra objects $A \in \text{Alg}(\mathfrak{C})$ and (strictly) associative algebra objects of $\mathcal{A}$ itself (Theorem 4.1.4.4). We will conclude this section by proving an analogous result for bimodules (Theorem 4.3.3.17). The key point is that we have a similar understanding of free bimodules in both $\mathcal{A}$ and $\mathfrak{C}$, thanks to Proposition 4.3.3.12.

Let $\mathcal{A}$ be a monoidal model category and let $A$ and $B$ be algebra objects of $\mathcal{A}$. We let $A \text{BMod}_B(\mathcal{A})$ denote the ordinary category of $A$-$B$-bimodule objects in $\mathcal{A}$. 

**Proposition 4.3.3.15.** Let $\mathcal{A}$ be a combinatorial monoidal model category and suppose that $A$ and $B$ are associative algebra objects of $\mathcal{A}$ which are cofibrant as objects of $\mathcal{A}$. Then $\mathcal{A} \text{BMod}_B(\mathcal{A})$ has the structure of a combinatorial model category, where:

(W) A morphism $f : M \to N$ is a weak equivalence in $\mathcal{A} \text{BMod}_B(\mathcal{A})$ if and only if it is a weak equivalence in $\mathcal{A}$.

(F) A morphism $f : M \to N$ is a fibration in $\mathcal{A} \text{BMod}_B(\mathcal{A})$ if and only if it is a fibration in $\mathcal{A}$.

The forgetful functor $\mathcal{A} \text{BMod}_B(\mathcal{A}) \to \mathcal{A}$ is both a left Quillen functor and a right Quillen functor. Moreover, if $\mathcal{A}$ is equipped with a compatible simplicial structure, then the induced simplicial structure on $\mathcal{A} \text{BMod}_B(\mathcal{A})$ endows $\mathcal{A} \text{BMod}_B(\mathcal{A})$ with the structure of a simplicial model category.

**Proof.** The proof is similar to that of Proposition 4.1.4.3. We first observe that $\mathcal{A} \text{BMod}_B(\mathcal{A})$ is presentable (Corollary 4.3.3.10). Let $T : \mathcal{A} \text{BMod}_B(\mathcal{A}) \to \mathcal{A}$ be the forgetful functor. Then $T$ admits a left adjoint given by the formula $F(X) = A \otimes X \otimes B$, and a right adjoint given by the formula $G(X) =^A X^B$. Since $\mathcal{A}$ is combinatorial, there exists a (small) collection of morphisms $I = \{ \iota_x : C \to C' \}$ which generates the class of cofibrations in $\mathcal{A}$, and a (small) collection of morphisms $J = \{ j_x : D \to D' \}$ which generates the class of trivial cofibrations in $\mathcal{A}$. Let $\overline{F(I)}$ be the weakly saturated class of morphisms in $\mathcal{A} \text{BMod}_B(\mathcal{A})$ generated by $\{ F(i) : i \in I \}$, and let $\overline{F(J)}$ be defined similarly. Unwinding the definitions, we see that a morphism in $\mathcal{A} \text{BMod}_B(\mathcal{A})$ is a trivial fibration if and only if it has the right lifting property with respect to $\overline{F(I)}$, for every $i \in I$. Invoking the small object argument, we deduce that every morphism $f : M \to N$ in $\mathcal{A} \text{BMod}_B(\mathcal{A})$ admits a factorization $M \to^l N \to^r N$ where $f' \in \overline{F(J)}$ and $f''$ is a trivial fibration. Similarly, we can find an analogous factorization where $f' \in \overline{F(J)}$ and $f''$ is a fibration. Using standard arguments, we are reduced to the problem of showing that each morphism belonging to $\overline{F(J)}$ is a weak equivalence in $\mathcal{A} \text{BMod}_B(\mathcal{A})$. Let $S$ be the collection of all morphisms $f : M \to N$ in $\mathcal{A} \text{BMod}_B(\mathcal{A})$ such that $T(f)$ is a trivial cofibration in $\mathcal{A}$. We wish to prove that $\overline{F(J)} \subseteq S$. Since $T$ preserves colimits, we conclude that $S$ is weakly saturated; it will therefore suffice to show that for each $j \in J$, $F(j) \in S$. In other words, we must show that if $j : X \to Y$ is a trivial cofibration in $\mathcal{A}$, then the induced map $A \otimes X \otimes B \to A \otimes Y \otimes B$ is again a trivial cofibration in $\mathcal{A}$. This follows immediately from the definition of a monoidal model category, in view of our assumption that $A$ and $B$ are cofibrant objects of $\mathcal{A}$. This completes the proof that $\text{LMod}_A(\mathcal{A})$ is a model category.

The forgetful functor $T : \mathcal{A} \text{BMod}_B(\mathcal{A}) \to \mathcal{A}$ is a right Quillen functor by construction. To see that $T$ is also a left Quillen functor, it suffices to show that the right adjoint $G : \mathcal{A} \to \mathcal{A} \text{BMod}_B(\mathcal{A})$ preserves fibrations and trivial fibrations. In view of the definition of fibrations and trivial fibrations in $\mathcal{A} \text{BMod}_B(\mathcal{A})$, this is equivalent to the assertion that the composition $T \circ G : \mathcal{A} \to \mathcal{A}$ preserves fibrations and trivial fibrations. This follows immediately from the definition of a monoidal model category, since $A$ and $B$ are assumed to be cofibrant in $\mathcal{A}$.

Now suppose that $\mathcal{A}$ is equipped with a compatible simplicial structure. We claim that $\mathcal{A} \text{BMod}_B(\mathcal{A})$ inherits the structure of a simplicial model category. For this, we suppose that $f : M \to N$ is a fibration in $\mathcal{A} \text{BMod}_B(\mathcal{A})$ and that $g : X \to Y$ is a cofibration of simplicial sets. We wish to show that the induced map $M^Y \to M^X \times_{N^X} N^Y$ is a fibration in $\text{LMod}_A(\mathcal{A})$, which is trivial if either $f$ or $g$ is trivial. This follows immediately from the analogous statement in the simplicial model category $\mathcal{A}$. \[\square\]

**Remark 4.3.3.16.** Proposition 4.3.3.15 admits the following generalization: suppose that $\mathcal{A}$ is a combinatorial model category, and that $F : \mathcal{A} \to \mathcal{A}$ is a left Quillen functor which is equipped with the structure of a monad (that is, an associative algebra in the monoidal category Fun(\mathcal{A}, \mathcal{A}) of endofunctors of $\mathcal{A}$). Then the category of algebras over $F$ inherits a model structure, where the fibrations and weak equivalences are defined at the level of the underlying objects of $\mathcal{A}$.

In the situation of Proposition 4.3.3.15, let $\mathcal{A}^c \subseteq \mathcal{A}$ and $(\mathcal{A} \text{BMod}_B(\mathcal{A}))^c \subseteq \mathcal{A} \text{BMod}_B(\mathcal{A})$ denote the full subcategories of $\mathcal{A}$ and $\mathcal{A} \text{BMod}_B(\mathcal{A})^c$ spanned by the cofibrant objects. Let $W$ be the collection of weak equivalences in $\mathcal{A}^c$ and $W'$ the collection of weak equivalences in $\mathcal{A} \text{BMod}_B(\mathcal{A})^c$. The monoidal functor
We will show that this diagram satisfies the hypotheses of Corollary 4.7.4.16:  

\[ N(A^c) \to N(A^c)[W^{-1}] \]  

determines a map  

\[ \theta : N_{ABMod_B}(A^c)[W'^{-1}] \to A_{BMod_B}(N(A^c)[W^{-1}]) \]  

(where we abuse notation by identifying \( A \) and \( B \) with their images in \( \text{Alg}(N(A^c)[W^{-1}]) \)).

**Theorem 4.3.3.17.** Let \( A \) be a combinatorial monoidal model category and let \( A, B \in \text{Alg}(A) \) be associative algebras in \( A \) which are cofibrant as objects of \( A \). Then the functor \( \theta : N_{ABMod_B}(A^c)[W'^{-1}] \to A_{BMod_B}(N(A^c)[W^{-1}]) \) described above is an equivalence of \( \infty \)-categories.

**Proof.** Consider the diagram  

\[
\begin{array}{ccc}
N(\text{A}_{\text{BMod}}(A^c))[W'^{-1}] & \xrightarrow{\theta} & A_{\text{BMod}}(N(A^c)[W^{-1}]) \\
\downarrow & & \downarrow \text{G} \\
N(A^c)[W^{-1}] & \xrightarrow{\text{G}'} & 
\end{array}
\]

We will show that this diagram satisfies the hypotheses of Corollary 4.7.4.16:

(a) The \( \infty \)-categories \( N(\text{A}_{\text{BMod}}(A^c))[W'^{-1}] \) and \( A_{\text{BMod}}(N(A^c)[W^{-1}]) \) admit geometric realizations of simplicial objects. In fact, both of these \( \infty \)-categories are presentable. For \( N(\text{A}_{\text{BMod}}(A^c))[W'^{-1}] \), this follows from Propositions 1.3.4.22 and 4.3.3.15. For \( A_{\text{BMod}}(N(A^c)[W^{-1}]) \), we first observe that \( N(A^c)[W^{-1}] \) is presentable (Proposition 1.3.4.22) and that left tensor product by \( A \) and right tensor product by \( B \) preserve small colimits (Corollary 4.1.4.8), and then apply Corollary 4.3.3.10.

(b) The functors \( G \) and \( G' \) admit left adjuncts \( F \) and \( F' \). The existence of a left adjoint to \( G \) follows from the fact that \( G \) is determined by a right Quillen functor. The existence of a left adjoint to \( G' \) follows from Corollary 4.3.3.14.

(c) The functor \( G' \) is conservative and preserves geometric realizations of simplicial objects. This follows from Corollaries 4.3.3.2 and 4.3.3.9.

(d) The functor \( G \) is conservative and preserves geometric realizations of simplicial objects. The first assertion is immediate from the definition of the weak equivalences in \( A_{\text{BMod}}(A) \), and the second follows from the fact that \( G \) is also a left Quillen functor.

(e) The natural map \( G' \circ F' \to G \circ F \) is an equivalence. Unwinding the definitions, we are reduced to proving that if \( N \) is a cofibrant object of \( A \), then the natural map \( N \to A \otimes N \otimes B \) induces an equivalence \( F'(N) \simeq A \otimes N \otimes B \). This follows from the explicit description of \( F' \) given in Corollary 4.3.3.13.

\[ \square \]

### 4.4 The Relative Tensor Product

Let \( A, B, \) and \( C \) be associative rings. Suppose that \( M \) is an \( A-B \)-bimodule, \( N \) is a \( B-C \)-bimodule, and \( X \) is an \( A-C \)-bimodule. A **bilinear pairing** \( f : M \times N \to X \) is a map \( f \) satisfying the equations

\[
\begin{align*}
f(m + m', n) &= f(m, n) + f(m', n) \\
f(m, n + n') &= f(m, n) + f(m, n') \\
f(0, n) &= f(m, 0) \\
f(m, 0) &= f(m, 0) \\
f(m, n) &= f(m, n) \\
f(m, n) &= f(m, n) \\
f(m, 0) &= f(m, 0) \\
f(m, n) &= f(m, n) \\
f(m, n) &= f(m, n)
\end{align*}
\]

\[ f(am, n) = af(m, n) \quad f(mb, n) = f(m, bn) \quad f(m, nc) = f(m, n)c. \]
4.4. THE RELATIVE TENSOR PRODUCT

We can reformulate this definition categorically as follows: a bilinear map is a map $F: M \otimes N \to X$ such that the diagrams

\[
\begin{array}{ccc}
A \otimes M \otimes N & \xrightarrow{F} & A \otimes X \\
m_{A,M} \otimes \text{id} & & m_{A,X} \\
A \otimes X & \xrightarrow{m_{A,X}} & X
\end{array}
\quad
\begin{array}{ccc}
M \otimes B \otimes N & \xrightarrow{F} & M \otimes N \\
m_{B,M} \otimes \text{id} & & m_{B,N} \\
M \otimes N & \xrightarrow{F} & X
\end{array}
\quad
\begin{array}{ccc}
M \otimes N \otimes C & \xrightarrow{F} & M \otimes N \\
\text{id} \otimes m_{C,N} & & m_{C,X} \\
X \otimes C & \xrightarrow{m_{C,X}} & X
\end{array}
\]

commute; here $m_{A,M}: A \otimes M \to M$ denotes the left action of $A$ on $M$, and the maps $m_{A,X}$, $m_{B,M}$, $m_{B,N}$, $m_{C,N}$, and $m_{C,X}$ are defined similarly. The advantage of this reformulation is that it makes sense more generally: if $\mathcal{C}$ is an arbitrary monoidal category containing algebra objects $A$, $B$, and $C$ and bimodules $M \in \mathcal{A}\text{BMod}_B(\mathcal{C})$, $N \in \mathcal{B}\text{Mod}_C(\mathcal{C})$, and $X \in \mathcal{A}\text{BMod}_C(\mathcal{C})$, then we can define a bilinear map from $M \otimes N$ to $X$ to be a map $F: M \otimes N \to X$ such that the above diagrams commute.

In §4.4.1, we will generalize the notion of a bilinear pairing to the setting of an arbitrary monoidal $\infty$-category $\mathcal{C}$. Under some mild hypotheses, one can show this notion determines a corepresentable functor: that is, we can associate to every pair of bimodules $M \in \mathcal{A}\text{BMod}_B(\mathcal{C})$ and $N \in \mathcal{B}\text{Mod}_C(\mathcal{C})$ a new bimodule $M \otimes_B N \in \mathcal{A}\text{BMod}_C(\mathcal{C})$, which is universal among bimodule objects which receive a $B$-bilinear map from the pair $(M, N)$. We will study the relative tensor product functor in §4.4.2. Note that the construction of $M \otimes_B N$ is somewhat more complicated than in the classical case: it is generally not given by the coequalizer of the diagram $M \otimes B \otimes N \xrightarrow{\eta} M \otimes N$. Instead it is computed by the classical two-sided bar construction: that is, as the geometric realization of the simplicial bimodule $\text{Bar}_B(M, N)$, given informally by the formula

$$\text{Bar}_B(M, N)_n = M \otimes B^\otimes n \otimes N.$$ 

In §4.4.3, we will use this description to show that (under reasonable hypotheses) the relative tensor product is unital and associative, up to coherent homotopy.

4.4.1 Multilinear Maps

Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category (or, more generally, a planar $\infty$-operad). Suppose we are given algebra objects $A, B, C \in \text{Alg}(\mathcal{C})$, together with bimodule objects

$$M \in \mathcal{A}\text{BMod}_B(\mathcal{C}) \quad N \in \mathcal{B}\text{Mod}_C(\mathcal{C}) \quad X \in \mathcal{A}\text{BMod}_C(\mathcal{C}).$$

Our goal in this section is to introduce the notion of a bilinear map from $M$ and $N$ into $X$. We will phrase our definition using the language of $\infty$-operads. Namely, we will introduce a correspondence of $\infty$-operads $\text{Tens}^\otimes \to \mathbb{N}(\text{Fin}_+) \times \Delta^1$ with the following properties:

(a) There is a homotopy pushout diagram of $\infty$-operads

\[
\begin{array}{ccc}
\text{Ass}^\otimes & \xrightarrow{i} & \text{BM}^\otimes \\
\downarrow j & & \downarrow \\
\text{BM}^\otimes & \longrightarrow & \text{Tens}^\otimes \times \Delta^1 \{0\},
\end{array}
\]

where $i$ is the inclusion $\text{Ass}^\otimes \simeq \text{Ass}^\otimes_+ \hookrightarrow \text{BM}^\otimes$ and $j$ the inclusion $\text{Ass}^\otimes \simeq \text{Ass}^\otimes_+ \hookrightarrow \text{BM}^\otimes$. In other words, giving a $\mathbb{M}_0$-algebra object of $\mathcal{C}$ is equivalent to giving a pair of bimodule objects $M \in \mathcal{A}\text{BMod}_B(\mathcal{C})$, $N \in \mathcal{B}\text{BMod}_C(\mathcal{C})$ such that $B' = B$.

(b) The fiber $\text{Tens}^\otimes \times \Delta^1 \{1\}$ is isomorphic to $\text{BM}^\otimes$, so a $\mathbb{M}_1$-algebra object of $\mathcal{C}$ is an object $X \in \mathcal{A}\text{BMod}_C(X)$. 

(c) Suppose we are given algebra objects \( \gamma_0 : \text{Tens}^\otimes \times \Delta^1 \{0\} \to \mathbb{C}^\otimes \) and \( \gamma_1 : \text{Tens}^\otimes \times \Delta^1 \{1\} \to \mathbb{C}^\otimes \), corresponding to a triple \( M \in A \text{BMod}_2 (\mathbb{C}) \), \( N \in B \text{BMod}_C (\mathbb{C}) \), and \( X \in A'_C \text{BMod}_C (\mathbb{C}) \). Then extending \( \gamma_0 \) and \( \gamma_1 \) to a map of generalized \( \infty \)-operads \( \text{Tens}^\otimes \to \mathbb{C}^\otimes \) is equivalent (by definition) to giving a pair of associative algebra maps \( A \to A', C \to C' \), together with a map \( M \otimes N \to X \) which is bilinear in the sense described above.

For later applications, it will be convenient to develop a more general theory of \( \text{multilinear maps} \). If \( \mathbb{C} \) is a symmetric monoidal \( \infty \)-category and we are given a sequence of bimodules \( M_{0,1} \in A_{0,1} \text{BMod}_A (\mathbb{C}) \), \( M_{1,2} \in A_{1,2} \text{BMod}_A \mathbb{C}) \), \( \ldots \), \( M_{n-1,n} \in A_{n-1,n} \text{BMod}_A (\mathbb{C}) \), \( X \in A_0 \text{BMod}_A (\mathbb{C}) \), then we can define the notion of a \( \text{multilinear map} \) from \( \{ M_{i-1,i} \}_{1 \leq i \leq n} \) to \( X \) in \( \text{morphism} \) \( \{1\} \). We let \( \text{Tens}^\otimes \) denote the nerve of the category \( \text{Tens}^\otimes \). Each \( \text{Tens}^\otimes \) induces an inert morphism \( \langle - \rangle \) from \( \{ M_{i-1,i} \}_{1 \leq i \leq n} \) to \( X \). In fact, something slightly stronger is true: the forgetful functor \( \text{Tens}^\otimes \to \mathbb{C}^\otimes \) is equivalent (by definition) to giving a \( \text{multilinear map} \) \( 0 \to 1 \). Notation 4.4.1.5. If \( A \) is an \( \infty \)-category and we are given a sequence of \( \text{bimodules} \) \( M \), then we let \( \text{Tens}^\otimes \) denote the functor \( \text{Tens}^\otimes \to \mathbb{C}^\otimes \). Proposition 4.4.1.2. If \( \text{Tens}^\otimes \to \mathbb{C}^\otimes \) exhibits \( \text{Tens}^\otimes \) as a \( \mathbb{C}^\otimes \text{family of } \infty \)-operads (in the sense of Definition 2.3.2.10). In particular, \( \text{Tens}^\otimes \) is a \( \mathbb{C}^\otimes \text{fibration of } \infty \)-operads.

Remark 4.4.1.3. In fact, something slightly stronger is true: the forgetful functor \( \text{Tens}^\otimes \to \mathbb{C}^\otimes \) is a \( \text{fibration of } \mathbb{C}^\otimes \text{-operads} \).

Remark 4.4.1.4. A morphism \( \alpha : (\langle n \rangle, [k], c_- c_+) \to (\langle n' \rangle, [k'], c'_- c'_+) \) in \( \text{Tens}^\otimes \) is inert if and only if it induces an inert morphism \( \langle n \rangle \to \langle n' \rangle \) in \( \mathbb{C}^\otimes \) and an isomorphism \( [k'] \to [k] \) in \( \Delta \).

Notation 4.4.1.5. If \( [n] \) is an object of \( \Delta^\otimes \), we let \( \text{Tens}^\otimes [n] \) denote the fiber product \( \text{Tens}^\otimes \times N(\Delta)^\otimes \{ [n] \} \). Each \( \text{Tens}^\otimes [n] \) is equipped with a \( \text{fibration of } \infty \)-operads \( \text{Tens}^\otimes [n] \to \mathbb{C}^\otimes \).

Example 4.4.1.6. The map \( \text{Tens}^\otimes \to \mathbb{C}^\otimes \) restricts to an isomorphism \( \text{Tens}^\otimes [0] \simeq \mathbb{C}^\otimes \).

Example 4.4.1.7. The \( \infty \)-operad \( \text{Tens}^\otimes [1] \) is isomorphic to the \( \infty \)-operad \( \text{BM}^\otimes \) of §4.3.1; see Notation 4.3.1.5.

Remark 4.4.1.8. Fix integer \( 0 \leq i \leq k \). Let \( 0(i)^\otimes \) denote the full subcategory of \( \text{Tens}^\otimes [k] \) spanned by objects of the form \( (\langle n \rangle, [k], c_- c_+) \) where \( c_- c_+ = c_+ c_- = i \) for \( 1 \leq m \leq k \). Then the composite map \( 0(i)^\otimes \subseteq \text{Tens}^\otimes [k] \to \mathbb{C}^\otimes \) is an isomorphism. Choosing a section, we obtain a map of \( \infty \)-operads \( c_i : \mathbb{C}^\otimes \to \text{Tens}^\otimes [k] \).
Notation 4.4.1.9. For $0 \leq i \leq k$, we let $a_i \in \text{Tens}_{[k]}$ denote the image of $(1) \in \text{Ass}$ under the embedding $\varepsilon_i : \text{Ass} \to \text{Tens}_{[k]}$ of Remark 4.4.1.8. If $0 \leq i, j \leq k$ with $j = i + 1$, we let $m_{i,j}$ denote the object of $\text{Tens}_{[k]}$ given by $((1), [k], c_-, c_+)$ where $c_-(1) = i$ and $c_+(1) = j$. Note that every object of $\text{Tens}_{[k]}$ has the form $a_i$ (for $0 \leq i \leq k$ or $m_{i,j}$ (for $0 \leq i, j \leq k$ with $j = i + 1$).

Let $\theta : \text{Tens}^\otimes_{[k]} \to \mathcal{C}^\otimes$ be a map of infinity-operads. For $0 \leq i \leq k$, $A_i = \theta(a_i) \in \mathcal{C}$ has the structure of an associative algebra object of $\mathcal{C}$. The intuition behind Definition 4.4.1.1 is the following: the functor $\theta$ is determined by the sequence of associative algebras $(A_0, \ldots, A_k)$, together with an $A_i$-$A_j$-bimodule $M_{i,j} = \theta(m_{i,j})$ when $j = i + 1$. Our first main result of this section (Proposition 4.4.1.11) makes this idea more precise. To state it, we will need a bit of terminology.

Notation 4.4.1.10. Every morphism $\alpha : [k] \to [k']$ in $\Delta$ determines an edge $\Delta^1 \to N(\Delta)^{op}$. We let $\text{Tens}^\otimes_\alpha$ denote the fiber product $\text{Tens}^\otimes \times_{N(\Delta)^{op}} \Delta^1$, so that $\text{Tens}^\otimes_\alpha$ is a correspondence of infinity-operads from $\text{Tens}^\otimes_{[k]} \times_{\Delta^1} \{0\} \simeq \text{Tens}^\otimes_{[k']} \times_{\Delta^1} \{1\} \simeq \text{Tens}^\otimes_{[k]}$. If the image of $\alpha$ is convex (that is, $\alpha(i + 1) \leq \alpha(i) + 1$ for $0 \leq i < k$), then this correspondence is associated with a map of infinity-operads $v_\alpha : \text{Tens}^\otimes_{[k]} \to \text{Tens}^\otimes_{[k']}$, given by composition with $\alpha$.

Given a nonempty linearly ordered set $I$, we let $\text{Tens}^\otimes_I$ denote the infinity-operad $\text{Tens}^\otimes_{[m]}$ where $m \geq 0$ is chosen so that there exists an isomorphism of linearly ordered sets $I \simeq [m]$. We will apply this notation in particular when $I$ is a convex subset of $[k]$ for some $k \geq 0$. In this case, the inclusion $I \to [k]$ induces a map of infinity-operads $\text{Tens}^\otimes_I \to \text{Tens}^\otimes_{[k]}$, which defines an isomorphism of $\text{Tens}^\otimes_I$ onto the full subcategory of $\text{Tens}^\otimes_{[k]}$ spanned by those objects $((m), [k], c_-, c_+)$ where $c_-, c_+ : (m)^\otimes \to [k]$ take values in $I$.

Proposition 4.4.1.11 (Segal Condition). Fix $k \geq 0$. Then $\text{Tens}^\otimes_{[k]}$ can be identified with the colimit (in the infinity-category $\text{Op}_{\infty}$ of infinity-operads) of the diagram

![Diagram](image)

For the purpose of proving Proposition 4.4.1.11 it will be useful to package the structure of the generalized infinity-operad $\text{Tens}^\otimes$ in a more compact form.

Definition 4.4.1.12. Let $\text{Step}$ denote the full subcategory of $\text{Fun}([1], \Delta)^{op}$ spanned by those morphisms $f : [n] \to [k]$ in $\Delta$ with the following property: for $1 \leq i \leq n$, we have $f(i) \leq f(i - 1) + 1$.

Let $\phi : \Delta^{op} \to \text{Ass}^\otimes$ be the functor of Construction 4.1.2.5. We define a functor $\Phi : \text{Step} \to \text{Tens}^\otimes$ such that the diagram

![Diagram](image)

- Let $f : [n] \to [k]$ be a morphism in $\Delta$, viewed as an object of $\text{Step}$. Then $\Phi(f) = (\phi([n]), [k], c_-, c_+)$, where $c_-, c_+ : (n)^\otimes \to [k]$ are given by $c_-(i) = f(i - 1)$, $c_+(i) = f(i)$.

- Let $\alpha$ be a morphism in $\text{Step}$, corresponding to a commutative diagram

$$
\begin{array}{ccc}
[n] & \xrightarrow{f} & [k] \\
\downarrow{\alpha_0} & & \downarrow{\alpha_1} \\
[n'] & \xrightarrow{f'} & [k'].
\end{array}
$$
Then $\Phi(\alpha)$ is the morphism $(\phi(\alpha_0), \alpha_1)$ of $\text{Tens}^\otimes$.

**Definition 4.4.1.13.** We will say that a morphism $\alpha$ in $\text{N(Step)}$ is *inert* if $\Phi(\alpha)$ is an inert morphism in the generalized $\infty$-operad $\text{Tens}^\otimes$.

**Remark 4.4.1.14.** We can identify a morphism $\alpha$ in $\text{N(Step)}$ with a commutative diagram

\[
\begin{array}{ccc}
[n] & \xrightarrow{f} & [k] \\
\downarrow{\alpha_0} & & \downarrow{\alpha_1} \\
[n'] & \xrightarrow{f'} & [k']
\end{array}
\]

in $\Delta$; using Remark 4.4.1.4, we conclude that $\alpha$ is inert if and only if $\alpha_1$ is an isomorphism and $\alpha_0$ satisfies $\alpha_0(i) = \alpha_0(i - 1) + 1$ for $1 \leq i \leq n$.

**Notation 4.4.1.15.** Let $S$ be an $\infty$-category equipped with a map $S \to \text{N}(\Delta)^{op}$. We let $\text{Tens}^\otimes_S$ denote the $S$-family of $\infty$-operads $\text{Tens}^\otimes \times_{\text{N}(\Delta)^{op}} S$, and $\text{N(Step)}_S$ the fiber product $\text{N(Step)} \times_{\text{N}(\Delta)^{op}} S$. We will say that a morphism in $\text{N(Step)}_S$ is inert if its image in $S$ is an equivalence and its image in $\text{N(Step)}$ is inert.

Suppose we are given a categorical fibration $\mathcal{C}^\otimes \to \text{Tens}^\otimes_S$ which exhibits $\mathcal{C}^\otimes$ as an $S$-family of $\infty$-operads. We let $\text{Alg}_{ss}(\mathcal{C})$ denote the full subcategory of $\text{Fun}_{\text{Tens}^\otimes_S}(\text{N(Step)}_S, \mathcal{C}^\otimes)$ spanned by those functors $F : \text{N(Step)}_S \to \mathcal{C}^\otimes$ which carry every inert morphism in $\text{N(Step)}_S$ to an inert morphism in $\mathcal{C}^\otimes$.

**Variant 4.4.1.16.** Suppose we are given a fibration of $\infty$-operads $\mathcal{C}^\otimes \to \text{Ass}^\otimes$. For every $\infty$-category $S$ equipped with a map $S \to \text{N}(\Delta)^{op}$, let $\mathcal{C}^\otimes_S$ denote the fiber product

\[
S \times_{\text{N}(\Delta)^{op}} \text{Tens}^\otimes \times_{\text{Ass}^\otimes} \mathcal{C}^\otimes.
\]

Then the induced map $\mathcal{C}^\otimes_S \to \text{Tens}^\otimes_S$ exhibits $\mathcal{C}^\otimes$ as an $S$-family of $\infty$-operads, so that the $\infty$-category $\text{Alg}_{ss}(\mathcal{C}_S)$ is defined as in Notation 4.4.1.15. We will abuse notation and denote this $\infty$-category simply by $\text{Alg}_{ss}(\mathcal{C})$; note that it can be identified with a full subcategory of $\text{Fun}_{\text{Ass}^\otimes}(\text{N(Step)}_S, \mathcal{C}^\otimes)$.

We can now formulate a precise sense in which the $\infty$-category $\text{N(Step)}$ is a “model” for the generalized $\infty$-operad $\text{Tens}^\otimes$.

**Proposition 4.4.1.17.** Let $S$ be an $\infty$-category equipped with a map $S \to \text{N}(\Delta)^{op}$, and suppose we are given a categorical fibration $q : \mathcal{C}^\otimes \to \text{Tens}^\otimes_S$ which exhibits $\mathcal{C}^\otimes$ as an $S$-family of $\infty$-operads. Then composition with the functor $\Phi : \text{N(Step)} \to \text{Tens}^\otimes$ of Definition 4.4.1.12 induces an equivalence of $\infty$-categories

\[
\text{Alg}_{/ \text{Tens}^\otimes_S}(\mathcal{C}) \to \text{Alg}_{ss}(\mathcal{C}).
\]

We defer the proof of Propositions 4.4.1.11 and 4.4.1.17 until the end of this section.

**Remark 4.4.1.18.** Proposition 4.1.2.15 is the special case of Proposition 4.4.1.17 where we assume that $S = \{0\}$.

Let $\mathcal{C}^\otimes$ be a planar $\infty$-operad. Since the $\infty$-operad $\text{Ass}^\otimes$ is coherent (Proposition 4.1.1.16), we can associate to each associative algebra $A \in \text{Alg}(\mathcal{C})$ a new planar $\infty$-operad $\text{Mod}^A_{\text{Ass}}(\mathcal{C})^\otimes$ (see §3.3.3). Our next goal is to show that the underlying $\infty$-category $\text{Mod}^A_{\text{Ass}}(\mathcal{C})$ is equivalent to the $\infty$-category $A\text{BMod}_A(\mathcal{C})$ of $A$-$A$-bimodule objects of $\mathcal{C}$. Moreover, we show that under this equivalence, the planar $\infty$-operad structure on $\text{Mod}^A_{\text{Ass}}(\mathcal{C})$ can be described in terms of the theory of multilinear maps developed in this section (see Theorem 4.4.1.28 for a precise statement). We begin by introducing some notation.
4.4. THE RELATIVE TENSOR PRODUCT

Definition 4.4.1.19. Let \( p : \mathcal{C}^\circ \to \text{Ass}^\circ \) be a fibration of \( \infty \)-operads. We define simplicial sets \( \overline{\text{Bim}}(\mathcal{C}) \) and \( \overline{\text{Bim}}'(\mathcal{C}) \) equipped with maps \( \overline{\text{Bim}}(\mathcal{C}) \to N(\Delta)^{op} \leftarrow \overline{\text{Bim}}'(\mathcal{C}) \) so that the following universal properties are satisfied: for every simplicial set \( K \), we have isomorphisms

\[
\text{Fun}_{N(\Delta)^{op}}(K, \text{Bim}(\mathcal{C})) \simeq \text{Fun}_{\text{Ass}^\circ}(K \times N(\Delta)^{op}, \text{Tens}^\circ, \mathcal{C}^\circ)
\]

\[
\text{Fun}_{N(\Delta)^{op}}(K, \text{Bim}'(\mathcal{C})) \simeq \text{Fun}_{\text{Ass}^\circ}(K \times N(\Delta)^{op}, N(\text{Step}), \mathcal{C}^\circ).
\]

Let \( \text{Bim}(\mathcal{C}) \) be the full simplicial subset of \( \overline{\text{Bim}}(\mathcal{C}) \) spanned by those vertices which determine \( \infty \)-operad maps \( \text{Tens}^\circ_{[n]} \to \mathcal{C}^\circ \) (for some \( n \geq 0 \)), and let \( \text{Bim}'(\mathcal{C}) \) be the full simplicial subset of \( \overline{\text{Bim}}'(\mathcal{C}) \) spanned by those vertices which correspond to maps \( N(\text{Step})_{[n]} \to \mathcal{C}^\circ \) which preserve inert morphisms (for some \( n \geq 0 \)).

Proposition 4.4.1.20. Let \( \mathcal{C}^\circ \to \text{Ass}^\circ \) be a fibration of \( \infty \)-operads. Then:

1. The maps \( \overline{\text{Bim}}(\mathcal{C}) \to N(\Delta)^{op} \leftarrow \overline{\text{Bim}}'(\mathcal{C}) \) are categorical fibrations of simplicial sets. In particular, both \( \overline{\text{Bim}}(\mathcal{C}) \) and \( \overline{\text{Bim}}'(\mathcal{C}) \) are \( \infty \)-categories.

2. The maps \( \text{Bim}(\mathcal{C}) \to N(\Delta)^{op} \leftarrow \text{Bim}'(\mathcal{C}) \) are categorical fibrations of simplicial sets. In particular, both \( \text{Bim}(\mathcal{C}) \) and \( \text{Bim}'(\mathcal{C}) \) are \( \infty \)-categories.

3. Composition with the functor \( \Phi : N(\text{Step}) \to \text{Tens}^\circ \) of Definition 4.4.1.12 induces an equivalence of \( \infty \)-categories \( \text{Bim}(\mathcal{C}) \to \text{Bim}'(\mathcal{C}) \).

Proof. Since \( \Delta \) is a category in which the only morphisms are identity maps, assertion (1) is equivalent to the statement that the maps \( \overline{\text{Bim}}(\mathcal{C}) \to N(\Delta)^{op} \leftarrow \overline{\text{Bim}}'(\mathcal{C}) \) are inner fibrations. This follows from Proposition B.3.14, since \( \text{Tens}^\circ \) and \( N(\text{Step}) \) are flat over \( N(\Delta)^{op} \) (Propositions 4.4.3.21 and 4.4.3.1). Assertion (2) is an immediate consequence of (1), since the inclusions \( \text{Bim}(\mathcal{C}) \subseteq \overline{\text{Bim}}(\mathcal{C}) \) and \( \text{Bim}'(\mathcal{C}) \subseteq \overline{\text{Bim}}'(\mathcal{C}) \) are categorical fibrations. To prove (3), it suffices to show that for every simplicial set \( S \) equipped with a map \( S \to N(\Delta)^{op} \), the induced map

\[
\text{Fun}_{N(\Delta)^{op}}(S, \overline{\text{Bim}}(\mathcal{C})) \to \text{Fun}_{N(\Delta)^{op}}(S, \overline{\text{Bim}}'(\mathcal{C}))
\]

is an equivalence of \( \infty \)-categories, which is a special case of Proposition 4.4.1.17. \( \square \)

Notation 4.4.1.21. Let \( \mathcal{C}^\circ \to \text{Ass}^\circ \) be a fibration of \( \infty \)-operads. For \( n \geq 0 \), we let \( \text{Bim}(\mathcal{C})_{[n]} \) and \( \text{Bim}'(\mathcal{C})_{[n]} \) denote the fiber products \( \text{Bim}(\mathcal{C}) \times_{N(\Delta)^{op}} \{[n]\} \) and \( \text{Bim}'(\mathcal{C}) \times_{N(\Delta)^{op}} \{[n]\} \). Unwinding the definitions, we see that \( \text{Bim}(\mathcal{C})_{[n]} \) can be identified with the \( \infty \)-category \( \text{Alg}_{\text{Tens}^\circ_{[n]}/\text{Ass}^\circ}(\mathcal{C}) \). In particular, we have canonical isomorphisms

\[
\text{Bim}(\mathcal{C})_{[0]} \simeq \text{Alg}(\mathcal{C}) \quad \text{Bim}(\mathcal{C})_{[1]} \simeq \Delta \text{Alg}(\mathcal{C}).
\]

Similarly, we have a canonical isomorphism \( \text{Bim}'(\mathcal{C})_{[0]} \simeq \Delta \text{Alg}(\mathcal{C}) \).

Notation 4.4.1.22. Let \( \text{Step}_0 \) denote the full subcategory of \( \text{Step} \) spanned by those objects which correspond to constant maps \( [n] \to [k] \) in \( \Delta \).

Remark 4.4.1.23. The forgetful functor \( \text{Step} \to \Delta^{op} \) induces a Cartesian fibration \( p : N(\text{Step}_0) \to N(\Delta)^{op} \). In particular, \( p \) is a flat categorical fibration (Example B.3.11). The fiber of \( p \) over an object \( [k] \in \Delta^0 \) is isomorphic to a disjoint union of \( k + 1 \) copies of \( N(\Delta)^{op} \).

Construction 4.4.1.24. Let \( \mathcal{C}^\circ \to \text{Ass}^\circ \) be a fibration of \( \infty \)-operads. We define a simplicial set \( \overline{\text{Bim}}_0(\mathcal{C}) \) equipped with a map \( \overline{\text{Bim}}_0(\mathcal{C}) \to N(\Delta)^{op} \) so that the following universal property is satisfied: for every simplicial set \( K \) equipped with a map \( K \to N(\Delta)^{op} \), there is a canonical isomorphism

\[
\text{Fun}_{N(\Delta)^{op}}(K, \overline{\text{Bim}}_0(\mathcal{C})) \simeq \text{Fun}_{\text{Ass}^\circ}(K \times N(\Delta)^{op}, N(\text{Step}_0), \mathcal{C}^\circ).
\]

We say that a morphism in \( \text{Step}_0 \) is inert if its image in \( \text{Step} \) is inert; let \( \text{Bim}_0(\mathcal{C}) \) be the full simplicial subset of \( \overline{\text{Bim}}(\mathcal{C}) \) spanned by those vertices which correspond to maps \( N(\text{Step}_0)_{[k]} \to \mathcal{C}^\circ \) which carry inert morphisms to inert morphisms (for some \( k \geq 0 \)).
Remark 4.4.1.25. Let \( \mathcal{C} \to \text{Ass}^{\otimes} \) be a fibration of \( \infty \)-operads. It follows from Theorem B.4.2 that the forgetful functor \( \text{Bim}_0^{\otimes}(\mathcal{C}) \to N(\Delta)^{op} \) is a coCartesian fibration. Moreover, for each \( k \geq 0 \) the fiber \( \text{Bim}_0^{\otimes}(\mathcal{C})[k] \) is canonically isomorphic to the product \( \text{Alg}(\mathcal{C})_{\leq k+1} \).

An object of \( \text{Bim}_0^{\otimes}(\mathcal{C})[k] \) can be thought of as a sequence of algebra objects \( (A_0, A_1, \ldots, A_k) \) of \( \mathcal{C} \), together with a sequence \( \{ M_i \}_{1 \leq i \leq n} \) where each \( M_i \) is an \( A_i - A_i \)-bimodule. The inclusion \( \text{Step}_0 \hookrightarrow \text{Step} \) induces a forgetful functor \( q : \text{Bim}_0^{\otimes}(\mathcal{C}) \to \text{Bim}_0^{\otimes}(\mathcal{C}) \). Informally, this functor forgets the data of the bimodules \( M_i \).

Remark 4.4.1.26. Let \( \mathcal{C} \to \text{Ass}^{\otimes} \) be a fibration of \( \infty \)-operads. There is an evident functor \( \text{Step}_0 \to \Delta^{op} \times \Delta^{op} \), given by the formula \( (f : [n] \to [k]) \mapsto ([n],[k]) \). Composition with this functor determines a diagonal map \( \delta : N(\Delta)^{op} \times \Delta \text{Alg}(\mathcal{C}) \to \text{Bim}_0^{\otimes}(\mathcal{C}) \). For each \( k \geq 0 \), the induced map of fibers \( \delta |_{[k]} : \{ [k] \} \times \Delta \text{Alg}(\mathcal{C}) \to \text{Bim}_0^{\otimes}(\mathcal{C})[k] \) can be identified with the diagonal map \( \Delta \text{Alg}(\mathcal{C}) \to \Delta \text{Alg}(\mathcal{C})^{k+1} \).

Construction 4.4.1.27. Let \( \mathcal{C} \to \text{Ass}^{\otimes} \) be a fibration of \( \infty \)-operads, and let \( \phi : \Delta^{op} \to \text{Ass}^{\otimes} \) be the functor described in Construction 4.1.25. Composition with \( \phi \) induces a map \( \text{N}(\text{Fun}([1], \Delta))^{op} \to \text{Fun}(\Delta^1, \text{Ass}^{\otimes}) \), which carries \( \text{N}(\text{Step}) \) into \( \mathcal{K}_{\text{Ass}} \) (see Notation 3.3.2.1). Composition with this functor induces a map \( \text{Mod}^{\text{Ass}}(\mathcal{C})^{\otimes} \times_{\text{Ass}^{\otimes}} N(\Delta)^{op} \to \text{Bim}^{\otimes}(\mathcal{C}) \). Unwinding the definitions, we see that the composition of this functor with the restriction map \( \text{Bim}^{\otimes}(\mathcal{C}) \to \text{Bim}_0^{\otimes}(\mathcal{C}) \) can be identified with the composition

\[
\text{Mod}^{\text{Ass}}(\mathcal{C})^{\otimes} \times_{\text{Ass}^{\otimes}} N(\Delta)^{op} \to (\text{Alg}(\mathcal{C}) \times \text{Ass}^{\otimes}) \times_{\text{Ass}^{\otimes}} N(\Delta)^{op} \to \Delta \text{Alg}(\mathcal{C}) \times N(\Delta)^{op} \to \text{Bim}_0^{\otimes}(\mathcal{C}) .
\]

Theorem 4.4.1.28. Let \( \mathcal{C} \to \text{Ass}^{\otimes} \) be a fibration of \( \infty \)-operads. Then the resulting diagram

\[
\begin{array}{ccc}
\text{Mod}^{\text{Ass}}(\mathcal{C})^{\otimes} \times_{\text{Ass}^{\otimes}} N(\Delta)^{op} & \longrightarrow & \text{Bim}^{\otimes}(\mathcal{C}) \\
\downarrow & & \downarrow \\
\text{Alg}(\mathcal{C}) \times N(\Delta)^{op} & \longrightarrow & \text{Bim}_0^{\otimes}(\mathcal{C})
\end{array}
\]

is a homotopy pullback square of \( \infty \)-categories.

Proof. Let \( \text{pAlg}_{/\text{Ass}}(\mathcal{C}) \) and \( \prod\text{Mod}^{\text{Ass}}(\mathcal{C})^{\otimes} \) be defined as in §3.3.3. We have a commutative diagram

\[
\begin{array}{ccc}
\text{Mod}^{\text{Ass}}(\mathcal{C}) \times_{\text{Ass}^{\otimes}} N(\Delta)^{op} & \longrightarrow & \prod\text{Mod}^{\text{Ass}}(\mathcal{C})^{\otimes} \times_{\text{Ass}^{\otimes}} N(\Delta)^{op} \\
\downarrow & & \downarrow \\
\text{Alg}(\mathcal{C}) \times N(\Delta)^{op} & \longrightarrow & \text{pAlg}_{/\text{Ass}}(\mathcal{C}) \times_{\text{Ass}^{\otimes}} N(\Delta)^{op} \\
\downarrow & & \downarrow \\
\text{Fun}_{\text{Ass}^{\otimes}}(S, \text{Mod}^{\text{Ass}}(\mathcal{C})) & \longrightarrow & \text{Fun}_{N(\Delta)^{op}}(S, \text{Bim}^{\otimes}(\mathcal{C}))
\end{array}
\]

In view of Remark 3.3.3.16, the horizontal maps on the left are categorical equivalences; it will therefore suffice to show that the square on the right is a homotopy pullback diagram. Fix an \( \infty \)-category \( S \) equipped with a map \( S \to N(\Delta)^{op} \); we will show that the induced diagram

\[
\begin{array}{ccc}
\text{Fun}_{\text{Ass}^{\otimes}}(S, \text{Mod}^{\text{Ass}}(\mathcal{C})) & \longrightarrow & \text{Fun}_{N(\Delta)^{op}}(S, \text{Bim}^{\otimes}(\mathcal{C})) \\
\downarrow & & \downarrow \\
\text{Fun}_{\text{Ass}^{\otimes}}(S, \text{pAlg}_{/\text{Ass}}(\mathcal{C})) & \longrightarrow & \text{Fun}_{N(\Delta)^{op}}(S, \text{Bim}_0^{\otimes}(\mathcal{C}))
\end{array}
\]

is a homotopy pullback square of \( \infty \)-categories.

We observe that the \( \infty \)-category \( \mathcal{K}_{\text{Ass}} \times \text{Ass}^{\otimes} \) is isomorphic to the nerve of a category \( D \): an object of \( D \) is given by a triple \( (n), \alpha \) where \( n \in \Delta^{op}, \alpha \in \text{Ass}^{\otimes} \), and \( \phi(n) \) is a semi-inert morphism (from \( \phi : \Delta^{op} \to \text{Ass}^{\otimes} \) is the functor described in Construction 4.1.25). Let \( \psi : \text{Step} \to D \) be the functor described in Construction 4.4.1.27, given on objects by \( \psi(f : [n] \to [k]) = ([k], \phi(n), \phi(f)) \). Let \( \mathcal{E} \) denote the categorical mapping cylinder of \( \psi \), which may be described more explicitly as follows:
4.4. THE RELATIVE TENSOR PRODUCT

- An object of $\mathcal{E}$ is either an object of $\mathcal{D}$ or an object of $\text{Step}$.
- Morphisms in $\mathcal{E}$ are given by the formula

$$\text{Hom}_\mathcal{E}(X, Y) = \begin{cases} \text{Hom}_\mathcal{D}(X, Y) & \text{if } X, Y \in \mathcal{D} \\
\text{Hom}_\text{Step}(X, Y) & \text{if } X, Y \in \text{Step} \\
\text{Hom}_\mathcal{D}(X, \psi Y) & \text{if } X \in \mathcal{D}, Y \in \text{Step} \\
\emptyset & \text{otherwise.} \end{cases}$$

Let $N(\mathcal{E})^0$ denote the full subcategory of $N(\mathcal{E})$ spanned by those objects which belong either to $\text{Step}_0$ or to $\mathcal{K}^0_{\text{Ass}} \subseteq \mathcal{K}_{\text{Ass}}$. Let $N(\mathcal{E})_S$ denote the fiber product $N(\mathcal{D}) \times_{N(\Delta)^{op}} S$, and define $N(\mathcal{E})^0_S$. Let $\text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})_S, \mathcal{C}^{op})$ be the full subcategory of $\text{Fun}_{\text{Ass}_S}(N(\mathcal{E})_S, \mathcal{C}^{op})$ spanned by those functors $F$ with the following properties:

(i) The functor $F$ is a $p$-left Kan extension of $F_0 = F|_{(\mathcal{K}^0_{\text{Ass}} \times_{\text{Ass}^{op}} S)}$.

(ii) The functor $F_0$ determines a map $S \to \text{Mod}^{\text{Ass}}(\mathcal{C})$.

Similarly, we let $\text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})^0_S, \mathcal{C}^{op})$ be the full subcategory of $\text{Fun}_{\text{Ass}_S}(N(\mathcal{E})^0_S, \mathcal{C}^{op})$ spanned by those functors $F$ which satisfy the following conditions:

(i') The functor $F$ is a $p$-left Kan extension of $F_0 = F|_{(\mathcal{K}^0_{\text{Ass}} \times_{\text{Ass}^{op}} S)}$.

(ii') The functor $F_0$ determines a map $S \to p\text{Alg}_{/\text{Ass}}(\mathcal{C})$.

Note that the inclusion $N(\text{Step}) \times_{N(\Delta)^{op}} S$ determines restriction maps

$$\text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})_S, \mathcal{C}^{op}) \to \text{Fun}_{N(\Delta)^{op}}(S, \text{Bim}'(\mathcal{C})) \quad \text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})^0_S, \mathcal{C}^{op}) \to \text{Fun}_{N(\Delta)^{op}}(S, \text{Bim}'_0(\mathcal{C})).$$

We have a commutative diagram

$$
\begin{array}{ccc}
\text{Fun}_{\text{Ass}_S}(S, \text{Mod}^{\text{Ass}}(\mathcal{C})) & \xrightarrow{\text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})_S, \mathcal{C}^{op})} & \text{Fun}_{N(\Delta)^{op}}(S, \text{Bim}'(\mathcal{C})) \\
\text{Fun}_{\text{Ass}_S}(S, p\text{Alg}_{/\text{Ass}}(\mathcal{C})) & \xrightarrow{\text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})^0_S, \mathcal{C}^{op})} & \text{Fun}_{N(\Delta)^{op}}(S, \text{Bim}'_0(\mathcal{C}))
\end{array}
$$

where the horizontal maps on the left are induced by the evident retraction map $r : \mathcal{E} \to \mathcal{D}$. Note that these left horizontal maps are sections of the restriction maps

$$\text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})_S, \mathcal{C}^{op}) \to \text{Fun}_{\text{Ass}_S}(S, \text{Mod}^{\text{Ass}}(\mathcal{C})) \quad \text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})^0_S, \mathcal{C}^{op}) \to \text{Fun}_{\text{Ass}_S}(S, p\text{Alg}_{/\text{Ass}}(\mathcal{C})),$$

which are trivial Kan fibrations (Proposition T.4.3.2.15). To complete the proof, it will therefore suffice to show that the square appearing on the right of the above diagram is a homotopy pullback. In fact, we will show that the map

$$\text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})_S, \mathcal{C}^{op}) \to \text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})^0_S, \mathcal{C}^{op}) \times_{\text{Fun}_{N(\Delta)^{op}}(S, \text{Bim}'(\mathcal{C}))} \text{Fun}_{N(\Delta)^{op}}(S, \text{Bim}'(\mathcal{C}))$$

is a trivial Kan fibration.

Let $N(\mathcal{E})^1_S$ be the full subcategory of $N(\mathcal{E})_S$ spanned by the objects of $N(\mathcal{E})^0_S$ together with the objects of $N(\text{Step}) \times_{N(\Delta)^{op}} S$. Let $\text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})^1_S, \mathcal{C}^{op})$ be the full subcategory of $\text{Fun}_{\text{Ass}_S}(N(\mathcal{E})^1_S, \mathcal{C}^{op})$ spanned by those functors $F$ such that $F|_{N(\mathcal{E})^1_S} \in \text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})^0_S, \mathcal{C}^{op})$ and $F|_{N(\text{Step}) \times_{N(\Delta)^{op}} S}$ determines a map $S \to \text{Bim}'(\mathcal{C})$. In view of Proposition T.4.3.2.15, it will suffice to prove the following:

(a) Every functor $F_0 \in \text{Fun}'_{\text{Ass}_S}(N(\mathcal{E})^1_S, \mathcal{C}^{op})$ admits a $p$-right Kan extension $F \in \text{Fun}_{\text{Ass}_S}(N(\mathcal{E})_S, \mathcal{C}^{op})$. 
(b) Let $F \in \text{Fun}_{\text{Ass}}^i(\mathcal{N}(\mathcal{E})_S, \mathcal{C}^\otimes)$ be an arbitrary functor such that $F_0 = F|_{\mathcal{N}(\mathcal{E})_S^1}$ belongs to the \infinite-category $\text{Fun}_{\text{Ass}}^i(\mathcal{N}(\mathcal{E})_S^1, \mathcal{C}^\otimes)$. Then $F$ is a $p$-right Kan extension of $F_0$ if and only if $F$ belongs to $\text{Fun}_{\text{Ass}}^i(\mathcal{N}(\mathcal{E})_S, \mathcal{C}^\otimes)$.

We first prove (a). Fix $F_0 \in \text{Fun}_{\text{Ass}}^i(\mathcal{N}(\mathcal{E})_S^1, \mathcal{C}^\otimes)$. According to Lemma T.4.3.2.13, it will suffice to show that for every object $X \in \mathcal{N}(\mathcal{E})_S$, if we set $\mathcal{X} = \mathcal{N}(\mathcal{E})_S^1 \times_{\mathcal{N}(\mathcal{E})_S} \mathcal{N}(\mathcal{E})_S$, then the map

$$\theta : \mathcal{X} \to \mathcal{N}(\mathcal{E})_S^1 \xrightarrow{F_0} \mathcal{C}^\otimes$$

can be extended to a $p$-limit diagram covering the evident map

$$\gamma : \mathcal{X} \to \mathcal{N}(\mathcal{E})_S \to \mathcal{N}(\Delta)^{\text{op}} \to \text{Ass}^\otimes.$$

Without loss of generality, we may assume that $X \not\in \mathcal{N}(\mathcal{E})_S^1$. Let $s \in S$ denote the image of $X$ and let $[k] \in \Delta^{\text{op}}$ be the image of $s$, so that we can identify $X$ with a semi-inert morphism $\phi([k]) \to \langle n \rangle$ in $\text{Ass}^\otimes$. Let $\mathcal{E}_{[k]}$ denote the fiber of the map $\mathcal{E} \to \Delta^{\text{op}}$ over the object $[k]$, and let $X'$ denote the image of $X$ in $\mathcal{E}_{[k]}$. Let $\mathcal{X}_0$ be the full subcategory of $\mathcal{E}_{[k]} \times \Delta^{\text{op}}$ spanned by morphisms of the form $\alpha : X \to Y$ which satisfy one of the following two conditions:

1. The object $Y$ belongs to $\mathcal{D}_{[k]}$ and corresponds to a null morphism $\phi([k]) \to \langle m \rangle$, and $\alpha$ induces an inert map $\langle n \rangle \to \langle m \rangle$.

2. The object $Y$ belongs to $\text{Step}_{[k]}$ and corresponds to a map $f : [m] \to [k]$. Moreover, the map $\alpha$ induces an inert map $\langle n \rangle \to \phi([m])$.

It is not difficult to show that the inclusion $\mathcal{X}_0 \to \mathcal{X}$ admits a right adjoint and is therefore right cofinal. Consequently, it will suffice to show that the restriction $\theta_0 = \theta|_{\mathcal{X}_0}$ can be extended to a $p$-limit diagram compatible with $\gamma$.

Let $\mathcal{X}_1 \subseteq \mathcal{X}_0$ be the full subcategory spanned by those objects which satisfy conditions (1) or (2) above, with $m = 1$. Using our assumption that $p$ is a fibration of $\infty$-operads, we deduce that $\theta_0$ is a $p$-right Kan extension of $\theta_1 = \theta|_{\mathcal{X}_1}$. Using Lemma T.4.3.2.7, we are reduced to proving that $\theta_1$ can be extended to a $p$-limit diagram (compatible with $\gamma$).

Let $\mathcal{X}_2 \subseteq \mathcal{X}_1$ be the full subcategory spanned by those objects which either satisfy condition (1) with $m = 1$, or satisfy the following stronger version of condition (2):

(2') The object $Y$ belongs to $\text{Step}_{[k]}$ and corresponds to the $f : [1] \simeq \{i - 1, i\} \to [k]$ for some $1 \leq i \leq k$. Moreover, the map $\alpha$ induces an inert map $\langle n \rangle \to \phi([m])$.

It is not hard to see that the inclusion $\mathcal{X}_2 \subseteq \mathcal{X}_1$ admits a right adjoint and is therefore right cofinal. We are therefore reduced to proving that $\theta_2 = \theta_1|_{\mathcal{X}_2}$ can be extended to a $p$-limit diagram (compatible with $\gamma$). We note that $\mathcal{X}_2$ is equivalent to a discrete simplicial set, whose objects are morphisms $\alpha_i : X \to X_i$ for $1 \leq i \leq n$. The existence of a $p$-limit of $\theta_2$ now follows from our assumption that $p$ is a fibration of $\infty$-operads. This proves (a). Moreover, the proof gives the following version of (b):

(b') Let $F \in \text{Fun}_{\text{Ass}}^i(\mathcal{N}(\mathcal{E})_S, \mathcal{C}^\otimes)$ be an arbitrary functor such that $F_0 = F|_{\mathcal{N}(\mathcal{E})_S^1}$ belongs to the \infinite-category $\text{Fun}_{\text{Ass}}^i(\mathcal{N}(\mathcal{E})_S^1, \mathcal{C}^\otimes)$. Then $F$ is a $p$-right Kan extension of $F_0$ if and only if, for every object $X \in \mathcal{N}(\mathcal{E})_S$ as above, each of the maps $F(\alpha_i)$ is an inert morphism in $\mathcal{C}^\otimes$.

To complete the proof, it will suffice show that if $F \in \text{Fun}_{\text{Ass}}(\mathcal{N}(\mathcal{E})_S, \mathcal{C}^\otimes)$, then $F$ satisfies conditions (i) and (ii) if and only if it satisfies the criterion of (b'). Assume first that $F$ satisfies (i) and (ii), and let $X \in \mathcal{N}(\mathcal{E})_S$ be as above. Fix $1 \leq i \leq n$: we wish to show that $F(\alpha_i)$ is an inert morphism in $\mathcal{C}^\otimes$. If $i$ does not lie in the image of the semi-inert morphism $\beta : \phi([k]) \to \langle n \rangle$, then $\alpha_i$ is an inert morphism in $\mathcal{X}_{\text{Ass}} \times \text{Ass}^\otimes \{s\}$ and the desired result follows from (ii). If $i = \beta(j)$ for $1 \leq j \leq k$, then $\alpha_i$ factors as a composition

$$X \xrightarrow{\alpha^i} \langle s, \rho^i : \langle n \rangle \to \langle 1 \rangle \rangle \xrightarrow{\alpha''} X'_i,$$
where $F(\alpha_i')$ is inert by virtue of (ii) and $F(\alpha_{ii}')$ is an equivalence by (i), from which it follows that $F(\alpha_i)$ is inert.

Now suppose that $F$ satisfies the criterion described in (b'); we wish to show that conditions (i) and (ii) are satisfied. We first prove (i). Fix an object $Y \in N(\text{Step}) \times_{N(\Delta)^{op}} S$, corresponding to a vertex $s \in S$ lying over $[k] \in \Delta^{op}$ and a map $f : [n] \to [k]$ in $\Delta$. Let $X \in N(\mathcal{E})_S$ be the image of $Y$ under the retraction $r$. We wish to prove that $F$ carries the natural map $X \to Y$ to an equivalence in $\mathcal{C}^\otimes$. For $1 \leq i \leq n$, let $\epsilon_i : Y \to Y_i$ be the morphism in $N(\text{Step}) \times_{N(\Delta)^{op}} \{s\}$ corresponding to the map $[1] \simeq \{i - 1, i\} \to [n]$. Since $F_0 \in \text{Fun}_{\Delta^{op}}(N(\mathcal{E})_S, \mathcal{C}^\otimes)$, we conclude that each $F(\epsilon_i)$ is an inert morphism in $\mathcal{C}^\otimes$. Since $\mathcal{C}^\otimes$ is an $\infty$-operad, it will suffice to show that each of the composite maps $F(X) \to F(Y) \to F(Y_i)$ is inert. If $i$ lies in the image of the map $\phi([k]) \to \phi([n])$, then this composition can be identified with $F(\alpha_i)$ and the desired result follows from the criterion of (b'). If $i$ does not belong to the image of $\phi([k])$, then the composite map factors as a composition

$$F(X) \xrightarrow{F(\alpha_i)} F(X_i) \to F(Y_i)$$

where $F(\alpha_i)$ is inert and the second map is an equivalence, since $F_0$ satisfies condition (i').

We now complete the proof by showing that $F$ satisfies (ii). In view of Remark 2.1.2.9, it will suffice to show that for every object $X \in N(\mathcal{E})_S$ corresponding to an object $s \in S$ lying over $[k] \in \Delta^{op}$ and a semi-inert morphism $\beta : \phi([k]) \to [n]$ as above, if we choose inert morphisms $\alpha_i' : X \to X_i = (s, \phi([k]) \to \{1\})$ lying over $\rho^i : [n] \to \{1\}$ for $1 \leq i \leq n$, then each $F(\alpha_i')$ is an inert morphism in $\mathcal{C}^\otimes$. If $i$ does not lie in the image of $\beta$, then $\alpha_i \simeq \alpha_i'$ and the desired result is an immediate consequence of the criterion of (b'). If $i$ does lie in the image of $\beta$, then $\alpha_i$ factors as a composition

$$X \xrightarrow{\alpha_i} X_i \to X_i.$$

Since $F(\alpha_i'')$ is an equivalence (by assumption (i'')) and $F(\alpha_i)$ is inert (by the criterion of (b'))), we conclude that $F(\alpha_i')$ is inert as desired.

We now turn to the proofs of Propositions 4.4.1.17 and 4.4.1.11.

**Proof of Proposition 4.4.1.17.** We use the same idea as in the proof of Theorem 2.3.3.23, though the details are slightly more complicated. First, let $\mathcal{J}$ denote the categorical mapping cylinder of the functor $\Phi$. That is, an object of $\mathcal{J}$ consists either of an object of $\text{Step}$ or an object of $\text{Tens}^\otimes$, with morphisms in $\mathcal{J}$ defined by the formula

$$\text{Hom}_\mathcal{J}(x, y) = \begin{cases} \text{Hom}_{\text{Step}}(x, y) & \text{if } x, y \in \text{Step} \\ \text{Hom}_{\text{Tens}^\otimes}(x, y) & \text{if } x, y \in \text{Tens}^\otimes \\ \text{Hom}_{\text{Tens}^\otimes}(x, \Phi(y)) & \text{if } x \in \text{Tens}^\otimes, y \in \text{Step} \\ \emptyset & \text{if } x \in \text{Step}, y \in \text{Tens}^\otimes. \end{cases}$$

We regard $\text{Tens}^\otimes$ and $\text{Step}$ as full subcategories of $\mathcal{J}$. Note that there is a retraction of $\mathcal{J}$ onto $\text{Tens}^\otimes$, whose restriction to $\text{Step}$ coincides with the functor $\Phi$. In particular, we can use the composite map $\mathcal{J} \to \text{Tens}^\otimes \to \Delta^{op}$ to define an $\infty$-category $N(\mathcal{J})_S = N(\mathcal{J}) \times_{N(\Delta)^{op}} S$. There is an evident functor $N(\mathcal{J})_S \to \Delta^1$, whose fibers are given by

$$N(\mathcal{J})_S \times_{\Delta^1} \{0\} \simeq \text{Tens}^\otimes_S \quad N(\mathcal{J})_S \times_{\Delta^1} \{1\} \simeq N(\text{Step})_S.$$

We will use these isomorphisms to identify $N(\text{Step})_S$ and $\text{Tens}^\otimes_S$ with full subcategories of $N(\mathcal{J})_S$. Moreover, the retraction of $\mathcal{J}$ onto $\text{Tens}^\otimes$ determines a retraction $r : N(\mathcal{J})_S \to \text{Tens}^\otimes_S$, whose restriction to $N(\text{Step})_S$ is the functor $\Phi_S : N(\text{Step})_S \to \text{Tens}^\otimes_S$ induced by $\Phi$.

Let $\mathcal{A}$ be the full subcategory of $\text{Fun}_{\text{Tens}^\otimes}(N(\mathcal{J})_S, \mathcal{C}^\otimes)$ spanned by those functors $F : N(\mathcal{J})_S \to \mathcal{C}^\otimes$ with the following properties:

(i) Let $x \in N(\text{Step})_S$ be an object and $\alpha : \Phi_S(x) \to x$ the evident map. Then $F(\alpha)$ is an equivalence in $\mathcal{C}^\otimes$.\[\Box\]
(ii) The restriction $F|\text{Tens}_S^\otimes$ belongs to $\text{Alg}_/\text{Tens}_S(\mathcal{C})$.

Conditions (i) and (ii) together imply that $F|\text{N(Step)}_S$ is equivalent to the composition $(F|\text{Tens}_S^\otimes)\circ \Phi_S$, and therefore $F$ also satisfies:

(iii) The restriction $F|\text{N(Step)}_S$ belongs to $\text{Alg}_S(\mathcal{C})$.

Note that the functor $\text{Alg}_/\text{Tens}_S(\mathcal{C}) \to \text{Alg}_S(\mathcal{C})$ factors as a composition

\[
\text{Alg}_/\text{Tens}_S(\mathcal{C}) \to A \to \text{Alg}_S(\mathcal{C})
\]

where the first map is given by composition with $r$. We note that $r$ has a left inverse, given by the restriction map $A \to \text{Alg}_/\text{Tens}_S(\mathcal{C})$. Note that a functor $F$ satisfies condition (i) if and only if $F$ is a $q$-left Kan extension of $F|\text{Tens}_S^\otimes$. Using Proposition T.4.3.2.15, we deduce that the $A \to \text{Alg}_/\text{Tens}_S(\mathcal{C})$ is a trivial Kan fibration, and therefore $r$ is an equivalence of $\infty$-categories. To complete the proof, it will suffice to show that the restriction map $A \to \text{Alg}_S(\mathcal{C})$ is also a trivial Kan fibration. In view of Proposition T.4.3.2.15, it will suffice to prove the following:

(a) Every $F_0 \in \text{Alg}_S(\mathcal{C})$ admits a $q$-right Kan extension $F \in \text{Fun}_{\text{Tens}_S^\otimes}(\text{N(Step)}_S, \mathcal{C}^\otimes)$.

(b) A functor $F \in \text{Fun}_{\text{Tens}_S^\otimes}(\text{N(Step)}_S, \mathcal{C}^\otimes)$ belongs to $A$ if and only if $F|\text{N(Step)}_S \in \text{Alg}_S(\mathcal{C})$ and $F$ is a $q$-right Kan extension of $F|\text{N(Step)}_S$.

We first prove (b). Choose a functor $F_0 \in \text{N(Step)}_S$; we wish to prove that $F_0$ admits a $q$-right Kan extension $F \in \text{Fun}_{\text{Tens}_S^\otimes}(\text{N(Step)}_S, \mathcal{C}^\otimes)$. Fix an object of $\mathcal{S} \in \text{Tens}_S^\otimes$, corresponding to an object $s \in S$ and an object $(\langle n \rangle, [k], c_-, c_+)$ having the same image in $\Delta^m$. Let $\mathcal{I}$ denote the $\infty$-category $\text{N(Step)}_S \times_A A_{\mathcal{I}}/\Delta^m$. According to Lemma T.4.3.2.13, it will suffice to show that the functor

\[
f : \mathcal{I} \to A_{\mathcal{I}}/\Delta^m \to A \to \text{Alg}_S(\mathcal{C})
\]

can be extended to a $q$-limit diagram lying over the map

\[
g : \mathcal{I} \to A_{\mathcal{I}}^\Delta \xrightarrow{\Phi} Tens_S^\otimes.
\]

Let $\mathcal{I}_0$ be the full subcategory of $\mathcal{I}$ spanned by those morphisms $\alpha : \mathcal{I} \to \Phi_S(\mathcal{I})$, where $\mathcal{I}$ is an object of $\text{N(Step)}_S$ lying over $t \in S$ and $\alpha$ induces an equivalence $s \to t$ in the $\infty$-category $S$. We note that the inclusion $\mathcal{I}_0 \subseteq \mathcal{I}$ admits a right adjoint and is therefore right cofinal. Consequently, we are reduced to proving that $f|\mathcal{I}_0$ can be extended to a $q$-limit diagram lying over $g|\mathcal{I}_0$.

Let $A_{\mathcal{I}}$ denote the fiber product $A \times_{\mathcal{I}} (s)$, let $\text{N(Step)}_S$ be defined similarly, and let $\mathcal{I}_1$ denote the fiber product $\text{N(Step)}_S \times_{A_{\mathcal{I}}} A_{\mathcal{I}}/\Delta^m$. Note that the canonical map $\mathcal{I}_1 \to \mathcal{I}$ restricts to an equivalence $\mathcal{I}_1 \simeq \mathcal{I}_0$. It therefore suffices to prove that $f|\mathcal{I}_1$ can be extended to a $q$-limit diagram lying over $g|\mathcal{I}_1$.

Unwinding the definitions, we can identify objects of $\mathcal{I}_1$ with pairs consisting of a map $\alpha : [m] \to [k]$ in $\Delta$ and a map $\beta : \langle n \rangle \to \phi([m])$ in $\text{Ass}^\otimes$ which satisfy the following condition:

- For $1 \leq j \leq m$, if $\beta^{-1}\{j\}$ is the linearly ordered set $\{i_0 < \cdots < i_k\}$, then we have

\[
\alpha(j - 1) = c_-(i_0) \leq c_+(i_0) = c_-(i_1) \leq c_+(i_1) = \cdots = c_-(i_k) \leq c_+(i_k) = \alpha(j) \leq \alpha(j - 1) + 1.
\]

Let $\mathcal{I}_2$ denote the full subcategory of $\mathcal{I}_1$ spanned by those pairs $(\alpha, \beta)$ such that $\beta$ is inert. We note that the inclusion $\mathcal{I}_2 \subseteq \mathcal{I}_1$ admits a right adjoint and is therefore right cofinal. We are therefore reduced to proving that $f|\mathcal{I}_2$ can be extended to a $q$-limit diagram lying over $g|\mathcal{I}_2$.

Let $\mathcal{I}_3$ be the full subcategory of $\mathcal{I}_2$ spanned by those pairs $(\alpha : [m] \to [k], \beta : \langle n \rangle \to \phi([m]))$ where $m = 1$. Using our assumption that $F_0 \in \text{Alg}_S(\mathcal{C})$, we deduce that $f|\mathcal{I}_3$ is a $q$-right Kan extension of $f|\mathcal{I}_3$. Using Lemma T.4.3.2.7, we are reduced to proving that $f|\mathcal{I}_3$ admits a $q$-limit diagram lying over $g|\mathcal{I}_3$. We note
that \( \mathcal{B}_3 \) is a discrete category whose objects correspond bijectively to the elements of \( \langle n \rangle^0 \). The existence of the desired extension now follows immediately from our assumption that \( \mathcal{C}^\otimes \to \text{Tens}^\otimes_{S} \) is a fibration of \( S \)-families of \( \infty \)-operads. This proves \((a)\). Let \( \mathcal{A}' \) be the full subcategory of \( \mathcal{F} \in \text{Fun}_{\text{Tens}^\otimes_{S}}(\langle n \rangle, \mathcal{C}^\otimes) \) spanned by those functors such that \( F|\text{N(Step)}_S \in \text{Alg}_S(\mathcal{C}) \) and \( F \) is a \( q \)-right Kan extension of \( F|\text{N(Step)}_S \). We obtain the following version of \((b)\):

\[(b') \text{ Let } F \in \text{Fun}_{\text{Tens}^\otimes_{S}}(\langle n \rangle, \mathcal{C}^\otimes) \text{ be a functor such that } F|\text{N(Step)}_S \text{ belongs to } \text{Alg}_S(\mathcal{C}). \text{ Then } F \in \mathcal{A}' \text{ if and only if, for every object } \pi \in \text{Tens}^\otimes_{S} \text{ as above, the maps } \{\rho^i : \langle n \rangle \to \phi([1])\}_{1 \leq i \leq n} \text{ exhibit } F(\pi) \text{ as a } q\text{-product of the objects } F(s, [1]; i) \text{ as above, if we let } \beta_i : \pi \xrightarrow{\alpha_i} \pi_i \to t_i \text{ is inert, which follows immediately from criterion } (b'). \]

**Proof of Proposition 4.4.1.11.** For every finite nonempty linearly ordered set \( I \), let \( \text{N(Step)}_I \) denote the fiber product \( \text{N(Step)}_I \times_{\text{N}(\mathcal{A}^0)} \{[m]\} \) where \( I \simeq [m] \). Let \( \overline{\text{N}(\text{Step})}_I = (\text{N}(\text{Step})_I, M_I) \), where \( M_I \) is the collection of inert morphisms in \( \text{N}(\text{Step})_I \); we regard \( \overline{\text{N}(\text{Step})}_I \) as an \( \infty \)-preoperad. The functor \( \Phi \) of Definition 4.4.1.12 defines a map of \( \infty \)-preoperads \( \overline{\text{N}(\text{Step})}_I \to \text{Tens}^\otimes_{I} \) (see Notation 2.1.4.5), and Proposition 4.4.1.17 implies that this map is a weak equivalence of \( \infty \)-preoperads. In view of Theorem T.4.2.4.1, it will suffice to show that \( \overline{\text{N}(\text{Step})}_I^{[k]} \) is a homotopy colimit of the diagram

\[
\begin{array}{cccc}
\text{N(Step)}_{\{0\}} & \cdots & \text{N(Step)}_{\{k-1, k\}} \\
\overline{\text{N}(\text{Step})}_{\{0, 1\}} & \cdots & \overline{\text{N}(\text{Step})}_{\{k-1\}} \\
\text{N(Step)}_{\{1\}} & \cdots & \text{N(Step)}_{\{k\}}
\end{array}
\]

in \( \mathcal{P} \mathcal{O} \mathcal{P}_{\infty} \). We observe that this diagram is cofibrant, and its colimit is isomorphic to the pair \( (\mathcal{X}, M) \), where \( \mathcal{X} \) is the full subcategory of \( \text{N(Step)}_I^{[k]} \) spanned by those objects \( f : [n] \to [k] \) whose image in \([k]\) has cardinality \( \leq 2 \) and \( M \) is the collection of inert morphisms in \( \mathcal{X} \). It will therefore suffice to show that the inclusion \( (\mathcal{X}, M) \subset \overline{\text{N}(\text{Step})}_I^{[k]} \) is a weak equivalence of \( \infty \)-preoperads. Unwinding the definitions, we must prove the following:

\[(*) \text{ Let } p : \mathcal{C}^\otimes \to \text{N}(\text{Fin}_n) \text{ be an } \infty \text{-operad. Then the restriction functor } \text{Fun}_{\text{N}(\text{Fin}_n)}(\text{N}(\text{Step})_I^{[k]}, \mathcal{C}^\otimes) \to \text{Fun}_{\text{N}(\text{Fin}_n)}(\mathcal{X}, \mathcal{C}^\otimes) \text{ induces a trivial Kan fibration } \text{Fun}_{\text{N}(\text{Fin}_n)}^0(\text{N}(\text{Step})_I^{[k]}, \mathcal{C}^\otimes) \to \text{Fun}_{\text{N}(\text{Fin}_n)}^0(\mathcal{X}, \mathcal{C}^\otimes), \text{ where } \text{Fun}_{\text{N}(\text{Fin}_n)}(\text{N}(\text{Step})_I^{[k]}, \mathcal{C}^\otimes) \text{ is the full subcategory of } \text{Fun}_{\text{N}(\text{Fin}_n)}(\text{N}(\text{Step})_I^{[k]}, \mathcal{C}^\otimes) \text{ spanned by those} \)

functors which carry inert morphisms in $N(\text{Step})|_k|$ to inert morphisms in $\mathcal{C}^\otimes$, and $\text{Fun}^{0}_{N(\mathcal{F}\text{in}_n)}(\mathcal{X}, \mathcal{C}^\otimes)$ is defined similarly.

In view of Proposition T.4.3.2.15, $(\ast)$ will follow from the following pair of assertions:

(a) Let $F_0 \in \text{Fun}_{N(\mathcal{F}\text{in}_n)}(\mathcal{X}, \mathcal{C}^\otimes)$ be a functor which carries every inert morphism in $\mathcal{X}$ to an inert morphism in $\mathcal{C}^\otimes$. Then $F_0$ admits a $p$-right Kan extension $F \in \text{Fun}_{N(\mathcal{F}\text{in}_n)}(N(\text{Step})|_k, \mathcal{C}^\otimes)$.

(b) Let $F \in \text{Fun}_{N(\mathcal{F}\text{in}_n)}(N(\text{Step})|_k, \mathcal{C}^\otimes)$ be a functor such that $F_0 = F|\mathcal{X}$ carries inert morphisms in $\mathcal{X}$ to inert morphisms in $\mathcal{C}^\otimes$. Then $F$ is a $p$-right Kan extension of $F_0$ if and only if $F$ carries inert morphisms in $N(\text{Step})|_k$ to inert morphisms in $\mathcal{C}^\otimes$.

We begin by proving $(a)$. Fix a functor $F_0 \in \text{Fun}_{N(\mathcal{F}\text{in}_n)}(\mathcal{X}, \mathcal{C}^\otimes)$ which carries inert morphisms in $\mathcal{X}$ to inert morphisms in $\mathcal{C}^\otimes$. Let $X$ be an object of $N(\text{Step})|_k$, corresponding to a map of linearly ordered sets $f : [n] \to [k]$. Let $\mathcal{X}_{X/} = \mathcal{X} \times_{N(\text{Step})|_k} (N(\text{Step})|_k)/_{X/}$; the objects of $\mathcal{X}_{X/}$ can be identified with maps of linearly ordered sets $g : [m] \to [n]$ such that $f \circ g$ carries $[m]$ to a convex subset of $[k]$ having cardinality at most $2$. According to Lemma T.4.3.2.13, it will suffice to show that the map $F_0|\mathcal{X}_{X/}$ can be extended to a $p$-limit diagram covering the evident map

$$\lambda : \mathcal{X}_{X/} \to (N(\text{Step})|_k)_{X/}^p \to N(\text{Step})|_k \to N(\mathcal{F}\text{in}_n).$$

Let $\mathcal{X}_{X/}^0$ be the full subcategory of $\mathcal{X}_{X/}$ spanned by those objects for which $g : [m] \to [n]$ is an injective map whose image is a convex subset of $[n]$. The inclusion $\mathcal{X}_{X/}^0 \subseteq \mathcal{X}_{X/}$ admits a right adjoint and so is right cofinal. It will therefore suffice to show that $F_0|\mathcal{X}_{X/}^0$ can be extended to a $p$-limit diagram covering $\lambda((\mathcal{X}_{X/}^0)^p)$. Let $\mathcal{X}_{X/}^1$ be the full subcategory of $\mathcal{X}_{X/}^0$ spanned by those objects $g : [m] \to [n]$ such that $m = 1$. Since $F_0$ preserves inert morphisms and $\mathcal{C}^\otimes$ is an $\infty$-operad, we conclude that $F_0|\mathcal{X}_{X/}^1$ is a $p$-right Kan extension of $F_0|\mathcal{X}_{X/}^0$. Using Lemma T.4.3.2.7, we are reduced to proving that $F_0|\mathcal{X}_{X/}^1$ can be extended to a $p$-limit diagram covering the map $\lambda((\mathcal{X}_{X/}^1)^p)$. We now observe that $\mathcal{X}_{X/}^1$ is isomorphic to a discrete simplicial set, whose objects correspond to the maps

$$\alpha_i : [1] \simeq \{i - 1, i\} \subseteq [n]$$

for $1 \leq i \leq n$, each of which determines determines an object $X_i \in \mathcal{X}$. We are therefore reduced to proving that there exists an object in $\mathcal{C}_{\mathcal{F}(n)}^\otimes$ which is a $p$-product of the objects $\{F_0(X_i) \in \mathcal{C}^\otimes|_{1 \leq i \leq n}\}$, which follows from our assumption that $\mathcal{C}^\otimes$ is an $\infty$-operad. This proves $(a)$. Moreover, the proof yields the following version of $(b)$:

(b') Let $F \in \text{Fun}_{N(\mathcal{F}\text{in}_n)}(N(\text{Step})|_k, \mathcal{C}^\otimes)$ be a functor such that $F_0 = F|\mathcal{X}$ carries inert morphisms in $\mathcal{X}$ to inert morphisms in $\mathcal{C}^\otimes$. Then $F$ is a $p$-right Kan extension of $F_0$ if and only if, for every object $X = (f : [n] \to [k]) \in N(\text{Step})|_k$ as above, the induced maps $F(X) \to F(X_i)$ are inert for $1 \leq i \leq n$.

Assertion $(b')$ immediately implies the “if” direction of $(b)$. For the converse, suppose that $F \in \text{Fun}_{N(\mathcal{F}\text{in}_n)}(N(\text{Step})|_k, \mathcal{C}^\otimes)$ is a functor which satisfies the conditions described in $(b')$; we wish to prove that $F$ preserves inert morphisms. Let $\beta : X \to X'$ be an inert morphism in $N(\text{Step})|_k$, corresponding to a commutative diagram

$$\begin{array}{ccc}
[n'] & \xrightarrow{h} & [n] \\
\downarrow{f'} & & \downarrow{f} \\
[k] & \xrightarrow{f} & [k]
\end{array}$$

such that $h$ carries $[n']$ isomorphically to a convex subset of $[n]$. We wish to prove that $F(\beta)$ is an inert morphism in $\mathcal{C}^\otimes$. Since $\mathcal{C}^\otimes$ is an $\infty$-operad, it will suffice to show that for every inert morphism $\gamma : F(X') \to
4.4. THE RELATIVE TENSOR PRODUCT

4.4.2 Tensor Products and the Bar Construction

Let $A$, $B$, and $C$ be associative rings, let $M$ be an $A$-$B$-bimodule, $N$ a $B$-$C$-bimodule, and $X$ an $A$-$C$-bimodule. In this situation, we can consider bilinear pairings from $M$ and $N$ into $X$. Such a pairing can be described either as a map of sets $\lambda : M \times N \to X$ satisfying suitable axioms (made explicit in the introduction to §4.4). However, there is another approach which is often more convenient. Namely, one can define the relative tensor product $M \otimes_B N$ to be the coequalizer of the diagram

$$M \otimes B \otimes N \xrightarrow{f} M \otimes N,$$

where $f$ is given by the right action of $B$ on $M$ and $g$ by the left action of $B$ on $N$. This coequalizer inherits a left action of $A$ and a right action of $C$, and may therefore be viewed as an $A$-$C$-bimodule. Moreover, it is not difficult to see that giving a bilinear pairing $M \times N \to X$ is equivalent to giving a map of $A$-$C$-bimodules $M \otimes_B N \to X$.

Our goal in this section is to generalize the theory of relative tensor products to the $\infty$-categorical setting. Let $\mathcal{C}$ be a monoidal $\infty$-category, and suppose we are given algebra objects $A, B, C \in \operatorname{Alg}(\mathcal{C})$ and bimodules $M \in \mathcal{A}_{\text{BMod}}(\mathcal{C})$ and $N \in \mathcal{B}_{\text{BMod}}(\mathcal{C})$. Our goal in this section is to define the relative tensor product $M \otimes_B N$ as an object of $\mathcal{A}_{\text{BMod}}(\mathcal{C})$. Our definition is based on the theory of operadic left Kan extensions developed in §3.1.2, applied to the correspondence of $\infty$-operads $\text{Tens}^\otimes_n$ introduced in §4.4.1. When the relevant operadic left Kan extension exists, it gives rise to a bimodule object $M \otimes_B N \in \mathcal{A}_{\text{BMod}}(\mathcal{C})$ with the following universal property: for any bimodule object $X \in \mathcal{A}_{\text{BMod}}(\mathcal{C})$, the space of maps from $M \otimes_B N$ into $X$ is homotopy equivalent to the space of bilinear pairings of $M$ and $N$ into $X$ (this follows formally from the universal property characterizing operadic left Kan extensions; see Theorem 3.1.2.3). The main result of this section (Theorem 4.4.2.8) gives a criterion which guarantees the existence of this operadic left Kan extension, together with a reasonably concrete description of it. In contrast with the classical case, the relative tensor product $M \otimes_B N$ can not be described as the coequalizer of the diagram

$$M \otimes B \otimes N \xrightarrow{f} M \otimes N.$$

Instead, we must replace this diagram by the more elaborate two-sided bar construction of Construction 4.4.2.7.

**Notation 4.4.2.1.** The morphism $[1] \simeq \{0, 2\} \hookrightarrow [2]$ in $\Delta$ determines a map of simplicial sets $\Delta^1 \to N(\Delta)^{op}$. We let $\text{Tens}^\otimes_\Delta$ denote the fiber product

$$\text{Tens}^\otimes \times_{N(\Delta)^{op}} \Delta^1.$$

**Remark 4.4.2.2.** The map $\text{Tens}^\otimes_\Delta \to \Delta^1$ is a correspondence of $\infty$-operads from $\text{Tens}^\otimes_{[2]} \simeq \text{Tens}^\otimes_\Delta \times_{\Delta^1} \{0\}$ to $\text{Tens}^\otimes_{[1]} \simeq \text{Tens}^\otimes_\Delta \times_{\Delta^1} \{1\} \simeq \mathcal{B}M^\otimes$.

Let $\mathcal{C}^\otimes$ be an $\infty$-operad. Proposition 4.4.1.11 guarantees that the canonical map

$$\text{Alg}_{\text{Tens}^\otimes_{[2]}}(\mathcal{C}) \to \text{BMod}(\mathcal{C}) \times_{\text{Alg}(\mathcal{C})} \text{BMod}(\mathcal{C})$$

is an equivalence of $\infty$-categories. In other words, we can identify objects of $\text{Alg}_{\text{Tens}^\otimes_{[2]}}(\mathcal{C})$ with pairs $M, N \in \text{BMod}(\mathcal{C})$ having the same image in $\text{Alg}(\mathcal{C})$ (that is, $M \in A_{\text{BMod}}(\mathcal{C})$ and $N \in B_{\text{BMod}}(\mathcal{C})$ for some $A, B, C \in \text{Alg}(\mathcal{C})$). Similarly, we can identify objects of $\text{Alg}_{\text{Tens}^\otimes_{[1]}}(\mathcal{C})$ with objects $X \in \text{BMod}(\mathcal{C})$. 

**Definition 4.4.2.3.** Let \( q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a fibration of \( \infty \)-operads and suppose we are given a map of generalized \( \infty \)-operads \( F : \text{Tens}^\otimes_{[2]} \to \mathcal{C}^\otimes \), such that \( F|\text{Tens}^\otimes_{[1]} \) determines a pair of bimodules object \( M, N \in \text{BMod}(\mathcal{C}) \) and \( F|\text{Tens}^\otimes_{[1]} \) is a bimodule object \( X \in \text{BMod}(\mathcal{C}) \). We will say that \( F \) exhibits \( X \) as a relative tensor product of \( M \) and \( N \) if \( F \) is an operadic \( q \)-colimit diagram.

Our main goal in this section is to give a criterion for the existence of relative tensor products.

**Notation 4.4.2.4.** Let \( \text{Step} \subseteq \text{Fun}([1], \Delta)^{op} \) be the category of appearing in Definition 4.4.1.12. We let \( u : \Delta^{op} \to \text{Step} \) be the functor given by the formula

\[
[n] \mapsto ([0] \star [n] \star [0] \simeq [n + 2] \xrightarrow{f} [2]),
\]

where \( f \) is given by the formula

\[
f(i) = \begin{cases} 
0 & \text{if } i = 0 \\
1 & \text{if } 0 < i < n + 2 \\
2 & \text{if } i = n + 2.
\end{cases}
\]

We can extend \( u \) to a functor \( u_+ : \Delta^{op}_{+} \to \text{Step} \), where \( u_+ \) carries the object \([-1] \in \Delta^{op}_{+}\) to the object \((\text{id} : [1] \to [1]) \in \text{Step} \). On morphisms, the extension \( u_+ \) is defined by assigning to each map \([n] \to [-1] \) in \( \Delta^{op}_{+} \) the morphism in \( \text{Step} \) corresponding to the commutative diagram

\[
\begin{array}{ccc}
[1] & \xrightarrow{\sim} & {0, n + 2} \\
\downarrow{\text{id}} & & \downarrow{f} \\
[1] & \xrightarrow{\sim} & {0, 2} \rightarrow [2].
\end{array}
\]

in \( \Delta \).

Composing \( u \) and \( u_+ \) with the functor \( \Phi : \text{Step} \to \text{Tens}^\otimes \) (and passing to nerves), we obtain functors \( U : \text{N}(\Delta)^{op} \to \text{Tens}^\otimes_{[2]} \) and \( U_+ : \text{N}(\Delta_{+})^{op} \to \text{Tens}^\otimes_{+} \).

**Proposition 4.4.2.5.** Suppose we are given a commutative diagram of generalized \( \infty \)-operads

\[
\begin{array}{ccc}
\text{Tens}^\otimes_{[2]} & \xrightarrow{F_0} & \mathcal{C}^\otimes \\
\downarrow{F} & & \downarrow{q} \\
\text{Tens}^\otimes & \xrightarrow{f} & \mathcal{O}^\otimes,
\end{array}
\]

where \( q \) is a fibration of \( \infty \)-operads and \( F_0 \) corresponds to a pair of bimodule objects \( M \in \mathcal{A}\text{BMod}_{B}(\mathcal{C}), N \in \mathcal{A}\text{BMod}_{C}(\mathcal{C}) \). Then there exists a dotted arrow \( F \) as indicated in the diagram, which exhibits \( X = F|\text{Tens}^\otimes_{[1]} \) as a relative tensor product of \( M \) and \( N \), if and only if the following conditions are satisfied:

(i) Let \( a_0, a_2 \in \text{Tens}_{[2]} \) and \( a_-, a_+ \in \text{Tens}_{[1]} \simeq \mathcal{B}M \) be as in Notation 4.4.1.9 and Definition 4.3.1.1. Then the evident maps \( f(a_0) \to f(a_-) \) and \( f(a_2) \to f(a_+) \) in \( \mathcal{O} \) can be lifted to morphisms \( A \to A', C \to C' \) in \( \mathcal{C} \), which are given by operadic \( q \)-colimit diagrams \( \Delta^1 \to \mathcal{C}^\otimes \).

(ii) Let \( U \) and \( U_+ \) be as in Notation 4.4.2.4. Then the composition \( f \circ U_+ \) can be lifted to an operadic \( q \)-colimit diagram extending the functor \( F_0 \circ U : \text{N}(\Delta)^{op} \to \mathcal{C}^\otimes \).

Moreover, if \( F : \text{Tens}^\otimes \to \mathcal{C}^\otimes \) is any map making the above diagram commute and \( X = F|\text{Tens}^\otimes_{[1]} \in \mathcal{A}\text{BMod}_{C}(\mathcal{C}) \), then \( F \) is an operadic \( q \)-left Kan extension of \( F_0 \) if and only if the following conditions are satisfied:
(i') The functor $F$ induces maps $A \to A'$ and $C \to C'$ which are given by operadic $q$-colimit diagrams $\Delta^1 \to \mathcal{C}^\otimes$.

(ii') The composition $F \circ U_+ : N(\Delta_+)^{op} \to \mathcal{C}^\otimes$ is an operadic $q$-colimit diagram.

Proof. The $\infty$-category $\text{Tens}[1] \simeq \mathcal{B}M$ has three objects, given by $a_-$, $m$, and $a_+$. Let $\mathcal{D}(a_-)$ denote the $\infty$-category $(\text{Tens}^\otimes_{\text{act}})_{a_-} \times_{\Delta^1} \{0\}$, and define $\mathcal{D}(m)$ and $\mathcal{D}(a_+)$ similarly. Assertions (i') and (ii') are immediate consequences of the following:

(i'') The inclusions $\{a_0\} \hookrightarrow \mathcal{D}(a_-)$ and $\{a_2\} \hookrightarrow \mathcal{D}(a_+)$ are left cofinal.

(ii'') The functor $U_+$ induces a left cofinal map $\theta : N(\Delta)^{op} \to \mathcal{D}(m)$.

Furthermore, conditions (i) and (ii) follow from (i'') and (ii'') together with Theorem 3.1.2.3. Assertion (i'') is obvious (the $\infty$-categories $\mathcal{D}(a_-)$ and $\mathcal{D}(a_+)$ contain $a_0$ and $a_2$ as final objects). To prove (ii''), we observe that $\theta$ admits a left adjoint. $\square$

Remark 4.4.2.6. In the situation of Proposition 4.4.2.5, suppose that the maps

$$f(a_0) \to f(a_-) \quad f(a_2) \to f(a_+)$$

are equivalences in $\mathcal{O}$. Then condition (i) is automatically satisfied, and condition (i') is equivalent to the requirement that the functor $F$ induces equivalences $A \to A'$ and $C \to C'$.

Our next goal is to make the construction of relative tensor products more explicit.

Construction 4.4.2.7. [Bar Construction] Let $U : N(\Delta)^{op} \to \text{Tens}_{[2]}^\otimes$ be as in Notation 4.4.2.4. The extension $U_+ : N(\Delta_+)^{op} \to \text{Tens}_{[2]}^\otimes$ determines a morphism $\beta : U \to U'$ in $\text{Fun}(N(\Delta)^{op}, \text{Tens}_{[2]}^\otimes)$, where $U' : N(\Delta)^{op} \to \text{Tens}[1] \subseteq \text{Tens}_{[2]}^\otimes$ is the constant functor taking the value $m \in \text{Tens}[1] \simeq \mathcal{B}M$.

Suppose we are given a commutative diagram of generalized $\infty$-operads

$$
\begin{array}{ccc}
\text{Tens}_{[2]}^\otimes & \xrightarrow{F_0} & \mathcal{C}^\otimes \\
\downarrow & & \downarrow q \\
\text{Tens}_{[2]}^\otimes & \xrightarrow{f} & \mathcal{O}^\otimes
\end{array}
$$

where $q$ is a coCartesian fibration of $\infty$-operads. The functor $F_0$ corresponds to a pair of bimodules $M \in \mathcal{A}\text{Mod}_B(\mathcal{C})$, $N \in \mathcal{B}\text{Mod}_C(\mathcal{C})$. Let $\mathcal{C}_m$ denote the fiber product $\mathcal{C}^\otimes \times_{\mathcal{O}^\otimes} \{m\}$, where

$$\{m\} \subseteq \text{Tens}_{[1]}^\otimes \subseteq \text{Tens}_{[2]}^\otimes$$

maps to $\mathcal{O}^\otimes$ via $f$.

Since $q$ is a coCartesian fibration, the natural transformation $f \circ U \to f \circ U'$ determined by $\beta$ can be lifted to a $q$-coCartesian natural transformation $F_0 \circ U \to X_\bullet$ in $\text{Fun}(N(\Delta)^{op}, \mathcal{C}^\otimes)$. Here $X_\bullet$ is a simplicial object of the $\infty$-category $\mathcal{C}_m$, which is well-defined up to a contractible space of choices. We will denote this simplicial object by $\text{Bar}_B(M, N)_\bullet$, and refer to it as the (two-sided) bar construction on $M$ and $N$.

Theorem 4.4.2.8. Let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a coCartesian fibration of $\infty$-operads which is compatible with $N(\Delta)^{op}$-indexed colimits, in the sense of Definition 3.1.1.18.

Suppose we are given a commutative diagram of generalized $\infty$-operads

$$
\begin{array}{ccc}
\text{Tens}_{[2]}^\otimes & \xrightarrow{F_0} & \mathcal{C}^\otimes \\
\downarrow & & \downarrow q \\
\text{Tens}_{[2]}^\otimes & \xrightarrow{f} & \mathcal{O}^\otimes
\end{array}
$$

This theorem provides a detailed description of how the relative tensor product is constructed, involving the bar construction and the coCartesian fibration.
where \( F_0 \) corresponds to a pair of bimodule objects \( M \in \mathbb{A}BMod_B(\mathcal{C}), N \in \mathbb{B}BMod_C(\mathcal{C}) \). Then there exists an extension \( F \) of \( F_0 \) as indicated in the diagram, which exhibits \( X = F|_{\mathbb{Tens}^\mathcal{C}_{[1]}} \) as a relative tensor product of \( M \) and \( N \). Moreover, if \( F \) is an arbitrary extension of \( F_0 \) making the above diagram commute, then \( F \) exhibits \( X \in \mathbb{A}BMod_B(\mathcal{C}) \) as a relative tensor product of \( M \) and \( N \) if and only if the following conditions are satisfied:

(i) The functor \( F \) induces \( q \)-coCartesian morphisms \( A \to A', B \to B' \).

(ii) The functor \( F \) induces an equivalence

\[
\lvert \text{Bar}_B(M, N)_\bullet \rvert \to F(m).
\]

Proof. Since \( N(\Delta)^{op} \) is weakly contractible, the projection map \( N(\Delta)^{op} \to \Delta^0 \) is left cofinal; it follows that \( q \) is also compatible with \( \Delta^0 \)-indexed colimits. The desired result now follows from Propositions 3.1.1.15, 3.1.1.16, and 4.4.2.5.

\[\]

Remark 4.4.2.9. In the situation of Construction 4.4.2.7, suppose that \( B \) is a trivial algebra object of the monoidal \( \infty \)-category \( \mathcal{C}^\otimes \) (see §3.2.1). Then the simplicial object \( \text{Bar}_B(M, N)_\bullet \) is essentially constant, so that \( \lvert \text{Bar}_B(M, N)_\bullet \rvert \) is equivalent to \( \text{Bar}_B(M, N)_0 \). It follows that the canonical map \( M \otimes N \to M \otimes_B N \) is an equivalence.

Definition 4.4.2.10. Let \( q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes \) be a coCartesian fibration of \( \infty \)-operads which is compatible with \( N(\Delta)^{op} \)-indexed colimits. Suppose we are given a map of generalized \( \infty \)-operads \( \text{Tens}_p^\mathcal{C} \to \mathcal{O}^\otimes \).

The formation of operadic \( q \)-left Kan extensions induces a functor

\[
T : \text{Alg}_{\text{Tens}^\mathcal{C}_{[2]} / \mathcal{O}}(\mathcal{C}) \to \text{Alg}_{\text{Tens}^\mathcal{C}_{[1]} / \mathcal{O}}(\mathcal{C}).
\]

We will refer to this functor as the relative tensor product functor. Given an object of \( \text{Alg}_{\text{Tens}^\mathcal{C}_{[2]} / \mathcal{O}}(\mathcal{C}) \) corresponding to a pair of bimodules \( M \in \mathbb{A}BMod_B(\mathcal{C}), N \in \mathbb{B}BMod_C(\mathcal{C}) \), we will denote the image of of pair \( (M, N) \) under the functor \( T \) by \( M \otimes_B N \).

Example 4.4.2.11. Let \( q : \mathcal{C}^\otimes \to \text{Ass}^\otimes \) be a monoidal \( \infty \)-category. Assume that \( \mathcal{C} \) admits geometric realizations of simplicial objects and that the tensor product functors \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations of simplicial objects separately in each variable (this is equivalent to the assumption that \( \otimes \) preserves geometric realizations of simplicial objects, since the simplicial set \( N(\Delta)^{op} \) is sifted). Consider the map of generalized \( \infty \)-operads given by the composition \( \text{Tens}_p^\mathcal{C} \to \mathcal{O}^\otimes \to \text{Ass}^\otimes \).

The relative tensor product determines a functor

\[
T : \text{BMod}(\mathcal{C}) \times_{\text{Alg}(\mathcal{C})} \text{BMod}(\mathcal{C}) \simeq \text{Alg}_{\text{Tens}^\mathcal{C}_{[2]} / \text{Ass}}(\mathcal{C}) \to \text{BMod}(\mathcal{C}).
\]

Criterion (i) of Theorem 4.4.2.8 guarantees that the diagram

\[
\begin{array}{ccc}
\text{BMod}(\mathcal{C}) \times_{\text{Alg}(\mathcal{C})} \text{BMod}(\mathcal{C}) & \xrightarrow{T} & \text{BMod}(\mathcal{C}) \\
\theta \downarrow & & \downarrow \\
\text{Alg}(\mathcal{C}) \times \text{Alg}(\mathcal{C}) & & \\
\end{array}
\]

commutes up to canonical homotopy; we may therefore assume without loss of generality that this diagram is commutative (since the map \( \theta \) is a categorical fibration). It follows that for every triple of algebra objects \( A, B, C \in \text{Alg}(\mathcal{C}) \), the functor \( T \) restricts to a map

\[
\mathbb{A}BMod_B(\mathcal{C}) \times \mathbb{B}BMod_C(\mathcal{C}) \to \mathbb{A}BMod_C(\mathcal{C}),
\]

which we will also refer to as the relative tensor product functor and denote by \( (M, N) \mapsto M \otimes_B N \in \mathbb{A}BMod_C(\mathcal{C}) \).
4.4. THE RELATIVE TENSOR PRODUCT

Example 4.4.2.12. There is a retraction $r$ of $\text{Tens}^\otimes$ onto the full subcategory $\text{Tens}^\otimes_{[1]} \subseteq \text{Tens}^\otimes$, which is given on $\text{Tens}^\otimes_{[2]}$ by composition with the map $u : [2] \to [1]$ in $\Delta$ defined by $u(0) = u(1) = 0 < 1 = u(2)$.

Let $q : \mathcal{E}^\otimes \to \mathcal{B}M^\otimes$ be a coCartesian fibration of $\infty$-operads, corresponding to an $\infty$-category $N = \mathcal{E}_m$ which is bitensored over a pair of monoidal $\infty$-categories $\mathcal{E}_-^\otimes$ and $\mathcal{E}_+^\otimes$. We note that $\text{Alg}_{\text{Tens}_{[2]}} / \mathcal{B}M^\otimes(\mathcal{E})$ can be identified with the fiber product

$$\text{BMod}(\mathcal{E}_-) \times_{\text{Alg}(\mathcal{E}_-)} \text{BMod}(N),$$

whose objects are pairs $(M, N)$ where $M \in \mathcal{A}\text{BMod}_B(\mathcal{E}_-)$, $N \in \mathcal{B}\text{Mod}_C(N)$ for some $A, B \in \text{Alg}(\mathcal{E}_-)$, $C \in \text{Alg}(\mathcal{E}_+)$. Assume that $q$ is compatible with $N(\Delta)^{\text{op}}$-indexed colimits: that is, the $\infty$-categories $\mathcal{E}_-, N$, and $\mathcal{E}_+$ admit geometric realizations of simplicial objects, and the tensor product functors

$$\mathcal{E}_- \times \mathcal{E}_- \to \mathcal{E}_- \quad \mathcal{E}_+ \times \mathcal{E}_+ \to \mathcal{E}_+$$

preserve geometric realizations separately in each variable. Then Theorem 4.4.2.8 defines a relative tensor product functor

$$\text{BMod}(\mathcal{E}_-) \times_{\text{Alg}(\mathcal{E}_-)} \text{BMod}(N) \simeq \text{Alg}_{\text{Tens}_{[2]} / \mathcal{B}M^\otimes(\mathcal{E})} \to \text{BMod}(N).$$

As in Example 4.4.2.11, we also obtain for every triple $A, B \in \text{Alg}(\mathcal{E}_-) \quad C \in \text{Alg}(\mathcal{E}_+)$ an induced functor

$$\mathcal{A}\text{BMod}_B(\mathcal{E}_-) \times \mathcal{B}\text{Mod}_C(N) \to \mathcal{A}\text{BMod}_C(N).$$

Remark 4.4.2.13. In the situation of Example 4.4.2.12, we obtain another retraction of $\text{Tens}^\otimes$ onto $\text{Tens}^\otimes_{[1]}$ using the map $u' : [2] \to [1]$ given by $u(0) = 0 < 1 = u(1) = u(2)$. This gives a relative tensor product functor

$$\mathcal{A}\text{BMod}_B(\mathcal{E}_-) \times \mathcal{B}\text{Mod}_C(\mathcal{E}_+) \to \mathcal{A}\text{BMod}_C(N)$$

defined for algebra objects $A \in \text{Alg}(\mathcal{E}_-)$ and $B, C \in \text{Alg}(\mathcal{E}_+)$. We conclude this section by studying the behavior of the relative tensor product with respect to colimits. First, we need to recall a bit of notation. For $i \in \{0, 1, 2\}$, we let $\text{Tens}^\otimes_{[i]}$ denote the full subcategory of $\text{Tens}^\otimes_{[2]}$ defined in Notation 4.4.1.10 (so that $\text{Tens}^\otimes_{[1]}$ is isomorphic to $\text{Ass}^\otimes$). We let $\text{Ass}^\otimes_-$ and $\text{Ass}^\otimes_+$ be the full subcategories of $\mathcal{B}M^\otimes \simeq \text{Tens}^\otimes_{[1]}$ defined in Remark 4.3.1.10. We regard $\text{Ass}^\otimes_-$, $\text{Ass}^\otimes_+$, and $\text{Ass}^\otimes_+$ as full subcategories of $\text{Tens}^\otimes_{[2]}$. Similarly, we let $\text{m}_0, 1, 2$ denote the objects of $\text{Tens}^\otimes_{[2]} \subseteq \text{Tens}^\otimes_{[1]} \subseteq \text{Tens}^\otimes_{[0]}$ the object defined in Remark 4.3.1.3.

Proposition 4.4.2.14. Let $K$ be a simplicial set and let $q : \mathcal{E}^\otimes \to \mathcal{O}^\otimes$ be a coCartesian fibration of $\infty$-operads which is compatible with $N(\Delta)^{\text{op}}$-indexed colimits and with $K$-indexed colimits.

Suppose we are given a map of generalized $\infty$-operads $\mathcal{T}^\otimes \to \mathcal{O}^\otimes$ and algebra objects $A \in \text{Alg}_{\mathcal{O}_- \mathcal{O}_+}(\mathcal{E})$, $B \in \text{Alg}_{\mathcal{O}_- \mathcal{O}_+}(\mathcal{E})$, and $C \in \text{Alg}_{\mathcal{O}_- \mathcal{O}_+}(\mathcal{E})$. Using Theorem 3.1.2.3, we can choose $q$-coCartesian natural transformations $A \to A'$ and $C \to C'$, where $A' \in \text{Alg}_{\mathcal{O}_- \mathcal{O}_+}(\mathcal{E})$ and $C' \in \text{Alg}_{\mathcal{O}_- \mathcal{O}_+}(\mathcal{E})$. Then the relative tensor product defines a functor

$$T : \mathcal{A}\text{BMod}_B(\mathcal{E}_{m_{0, 1}}) \times \mathcal{B}\text{Mod}_C(\mathcal{E}_{m_{1, 2}}) \to \mathcal{A}\text{BMod}_B(\mathcal{E}_{m})$$

which preserves $K$-indexed colimits separately in each variable.

Corollary 4.4.2.15. Let $\mathcal{E}^\otimes$ be a monoidal $\infty$-category and $K$ a simplicial set. Assume that the tensor product functor $\otimes : \mathcal{E} \times \mathcal{E} \to \mathcal{E}$ preserves $N(\Delta)^{\text{op}}$-indexed colimits and $K$-indexed colimits separately in each variable, and let $A, B, C \in \text{Alg}(\mathcal{E})$. Then the relative tensor product functor

$$\mathcal{A}\text{BMod}_B(\mathcal{E}) \times \mathcal{B}\text{Mod}_C(\mathcal{E}) \to \mathcal{A}\text{BMod}_C(\mathcal{E})$$

preserves $K$-indexed colimits separately in each variable.
Corollary 4.4.2.16. Let $\mathcal{N}$ be an $\infty$-category which is bitensored over a pair of monoidal $\infty$-categories $\mathcal{C}_-^\otimes$ and $\mathcal{C}_+^\otimes$. Let $K$ be a simplicial set. Assume that the tensor product functors
\[
\mathcal{C}_- \times \mathcal{C}_- \to \mathcal{C}_- \quad \mathcal{C}_+ \times \mathcal{C}_+ \to \mathcal{C}_+
\]
preserve $\mathcal{N}(\Delta)^{op}$-indexed colimits and $K$-indexed colimits separately in each variable. Given a triple of algebra objects $A, B \in \text{Alg}(\mathcal{C}_-)$, $C \in \text{Alg}(\mathcal{C}_+)$, the relative tensor product functor
\[
\mathcal{A}B\text{Mod}_B(\mathcal{C}_-) \times \mathcal{B}\text{Mod}_C(\mathcal{N}) \to \mathcal{A}B\text{Mod}_C(\mathcal{N})
\]
of Example 4.4.2.12 preserves $K$-indexed colimits separately in each variable.

Proof of Proposition 4.4.2.14. In view of Proposition 4.3.3.9, it will suffice to show that the composite functor
\[
\mathcal{A}B\text{Mod}_B(\mathcal{C}_{m_0,1}) \times \mathcal{B}\text{Mod}_C(\mathcal{C}_{m_1,2}) \xrightarrow{T} \mathcal{A}B\text{Mod}_B(\mathcal{C}_m) \to \mathcal{C}_m
\]
preserves $K$-indexed colimits separately in each variable. Theorem 4.4.2.8 shows that this composite functor is given by $(M, N) \mapsto \{\text{Bar}_B(M, N)_k\}$. In view of Lemma T.5.5.2.3, it will suffice to show that for each $k \geq 0$, the functor
\[
\theta : \mathcal{A}B\text{Mod}_B(\mathcal{C}_{m_0,1}) \times \mathcal{B}\text{Mod}_C(\mathcal{C}_{m_1,2}) \to \mathcal{C}_m
\]
given by $(M, N) \mapsto \text{Bar}_B(M, N)_k$ preserves $K$-indexed colimits separately in each variable. We note that $\theta$ factors as a composition
\[
\mathcal{A}B\text{Mod}_B(\mathcal{C}_{m_0,1}) \times \mathcal{B}\text{Mod}_C(\mathcal{C}_{m_1,2}) \xrightarrow{\phi \times \psi} \mathcal{C}_{m_0,1} \times \mathcal{C}_{m_1,2} \xrightarrow{\theta'} \mathcal{C}_m.
\]
Here the functors $\phi$ and $\psi$ preserve $K$-indexed colimits by Proposition 4.3.3.9, and the functor $\theta'$ preserves $K$-indexed colimits separately in each variable by virtue of our assumption that $q : \mathcal{C}_\otimes \to \mathcal{O}_\otimes$ is compatible with $K$-indexed colimits.

4.4.3 Associativity of the Tensor Product

Let $\mathcal{A}b$ denote the category of abelian groups. If $A$ and $B$ are rings, we let $\mathcal{A}B\text{Mod}_B(\mathcal{A}b)$ denote the category of $A$-$B$-bimodules. Suppose we are given associative rings $A$, $B$, $C$, and $D$, together with bimodules $M \in \mathcal{A}B\text{Mod}_B(\mathcal{A}b)$, $N \in \mathcal{B}\text{Mod}_C(\mathcal{A}b)$, and $P \in \mathcal{C}\text{Mod}_D(\mathcal{A}b)$. Then there is a canonical isomorphism of $A$-$D$-bimodules
\[
M \otimes_B (N \otimes_C P) \simeq (M \otimes_B N) \otimes_C P.
\]
To see this, it suffices to show that $M \otimes_B (N \otimes_C P)$ and $(M \otimes_B N) \otimes_C P$ corepresent the same functor on the category $\mathcal{A}B\text{Mod}_D()$. In fact, for any $A$-$D$-bimodule $X$, both $\text{Hom}_{\mathcal{A}B\text{Mod}_D()}(M \otimes_B N \otimes_C P, X)$ and $\text{Hom}_{\mathcal{A}B\text{Mod}_D()}(M \otimes_B (N \otimes_C P), X)$ can be identified with the set of maps $f : M \times N \times P \to X$ satisfying the conditions
\[
\begin{align*}
f(m + m', n, p) &= f(m, n, p) + f(m', n, p) \\
f(m, n + n', p) &= f(m, n, p) + f(m, n', p) \\
f(m, n, p + p') &= f(m, n, p) + f(m, n, p') \\
f(am, n, p) &= af(m, n, p) \\
f(mh, n, p) &= f(m, bn, p) \\
f(m, nc, p) &= f(m, np) \\
f(m, npd) &= f(m, np)d.
\end{align*}
\]
Our goal in this section is to prove an analogous associativity property for the tensor product of bimodule objects in an arbitrary monoidal $\infty$-category. The crucial ingredient is the following technical result, whose proof will be given at the end of this section:
Theorem 4.4.3.1. The forgetful functor $\text{Tens}^\otimes \to N(\Delta)^{op}$ is a flat categorical fibration (see Definition B.3.8).

Corollary 4.4.3.2. Let $S$ be a simplicial set equipped with a map $S \to N(\Delta)^{op}$, and let $\text{Tens}^\otimes_S$ be the $S$-family of $\infty$-operads defined in Notation 4.4.1.15. For every simplex $\sigma : \Delta^n \to S$, we let $\text{Tens}^\otimes_{\sigma}$ denote the fiber product $\text{Tens}^\otimes_S \times_S \Delta^n$.

Suppose we are given a fibration of $\infty$-operads $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ and a map of generalized $\infty$-operads $\text{Tens}^\otimes_S \to \mathcal{O}^\otimes$. Suppose further that the following condition is satisfied:

(*) For every edge $\alpha : s \to s'$ in $S$ and every $F_0 \in \text{Alg}_{\text{Tens}^\alpha} / \mathcal{O}(\mathcal{C})$, there exists an operadic $q$-left Kan extension $F \in \text{Alg}_{\text{Tens}^\alpha} / \mathcal{O}(\mathcal{C})$ of $F_0$.

Define a map of simplicial sets $p : X \to S$ so that the following universal property is satisfied: for every map of simplicial sets $K \to S$, there is a canonical bijection $\text{Hom}(\text{set}_{\Delta})_X(K, X) \simeq \text{Alg}_{\text{Tens}^R} / \mathcal{O}(\mathcal{C})$. Then the projection map $p : X \to S$ is a coCartesian fibration. Moreover, if $\overline{\alpha}$ is an edge of $X$ with $p(\overline{\alpha}) = \alpha : s \to s'$, then $\overline{\alpha}$ is $p$-coCartesian if and only if it corresponds to an object $F \in \text{Alg}_{\text{Tens}^\alpha} / \mathcal{O}(\mathcal{C})$ which is an operadic $q$-left Kan extension of $F_0 = F|\text{Tens}^\otimes$.

Proof. It follows from Theorem 4.4.3.1 that $p$ is an inner fibration. Let us call an edge $\overline{\alpha}$ of $X$ special if $p(\overline{\alpha}) = \alpha : s \to s'$ and $\overline{\alpha}$ corresponds to an object $F \in \text{Alg}_{\text{Tens}^\alpha} / \mathcal{O}(\mathcal{C})$ which is an operadic $q$-left Kan extension of $F_0 = F|\text{Tens}^\otimes$. Theorem 3.1.2.3 implies that every special edge of $X$ is $p$-coCartesian. It follows from (*) that $p$ is a locally coCartesian fibration. Using Theorem 4.4.3.1 and Theorem 3.1.4.1, we conclude that the class of special edges is closed under composition, so that $p$ is a coCartesian fibration (Proposition T.2.4.2.8).

To apply Corollary 4.4.3.2 in practice, we need to describe the functors induced by operadic left Kan extension along correspondences of the form $\text{Tens}^\otimes_{\alpha} = \text{Tens}^\otimes \times_{N(\Delta)^{op}} \Delta^1$, where $\Delta^1 \to N(\Delta)^{op}$ is induced by a morphism $\alpha : [n] \to [m]$ in $\Delta$.

Notation 4.4.3.3. Let $\alpha : [n] \to [m]$ be a morphism in $\Delta$, which we identify with a map $\Delta^1 \to N(\Delta)^{op}$. We let $\text{Tens}^\otimes_{\alpha}$ denote the fiber product $\text{Tens}^\otimes \times_{N(\Delta)^{op}} \Delta^1$. We observe that $\text{Tens}^\otimes_{\alpha}$ can be identified with a correspondence of $\infty$-operads from $\text{Tens}^\otimes_{[m]}$ to $\text{Tens}^\otimes_{[n]}$. For $0 \leq i \leq m$, we let $\alpha_i \in \text{Tens}^\otimes_{[m]} \subseteq \text{Tens}^\otimes_{[n]}$ be defined as in Notation 4.4.1.9, and for $0 \leq i < m$ we let $\alpha_{i,i+1} \in \text{Tens}^\otimes_{[m]} \subseteq \text{Tens}^\otimes_{[n]}$ defined similarly. To avoid confusion, we will denote the corresponding objects of $\text{Tens}^\otimes_{[n]} \subseteq \text{Tens}^\otimes_{[m]}$ by $\{b_j\}_{0 \leq j \leq n}$ and $\{n_{j,j+1}\}_{0 \leq j < n}$.

We would like to analyze the behavior of operadic left Kan extension along a correspondence of the form $\text{Tens}^\otimes_{\alpha}$. We begin by considering an easy special case.

Remark 4.4.3.4. Let $\alpha : [n] \to [m]$ be a map of linearly ordered sets. Assume that the image of $\alpha$ is convex (that is, we have $\alpha(i+1) \leq \alpha(i) + 1$ for $0 \leq i < n$). We let $v_\alpha : \text{Tens}^\otimes_{[n]} \to \text{Tens}^\otimes_{[m]}$ be the map given by composition with $\alpha$ (Notation 4.4.1.10).

The projection map $\text{Tens}^\otimes_{\alpha} \to \Delta^1$ is the Cartesian fibration associated to the induced functor $\text{Tens}^\otimes_{[n]} \to \text{Tens}^\otimes_{[m]}$. It follows that for every object $X \in \text{Tens}^\otimes_{[n]}$, the $\infty$-category $\text{Tens}^\otimes_{[m]} \times_{\text{Tens}^\otimes(\text{Tens}^\otimes_{\alpha})/X}$ contains $v_\alpha(X)$ as a final object.

Combining Remark 4.4.3.4 and Theorem 3.1.2.3, we deduce:

Lemma 4.4.3.5. Let $\alpha : [n] \to [m]$ be a morphism in $\Delta$ with convex image and let $q : \mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a fibration of $\infty$-operads. Suppose we are given a diagram of generalized $\infty$-operads

\[
\begin{array}{ccc}
\text{Tens}^\otimes_{[m]} & \xrightarrow{F_0} & \mathcal{C}^\otimes \\
F & \downarrow & q \\
\text{Tens}^\otimes_{\alpha} & \xrightarrow{f} & \mathcal{O}^\otimes
\end{array}
\]

Then:
There exists a functor $F$ as indicated in the diagram, which is an operadic $q$-left Kan extension of $F_0$, if and only if for every object $X \in \text{Tens}_{[n]}$, there exists a map $F_0(v_{\alpha}X) \rightarrow C$ in $\mathcal{C}$ lying over the map $f(v_{\alpha}X) \rightarrow f(X)$, given by an operadic $q$-colimit diagram $\Delta^1 \rightarrow \mathcal{C}^\otimes$.

(2) Let $F : \text{Tens}^\otimes_{\alpha} \rightarrow \mathcal{C}^\otimes$ be any map of generalized $\infty$-operads making the above diagram commute. Then $F$ is an operadic $q$-left Kan extension of $F_0$ if and only if, for each $X \in \text{Tens}_{[n]}$, the induced map $F(v_{\alpha}X) \rightarrow F(X)$ is given by an operadic $q$-colimit diagram $\Delta^1 \rightarrow \mathcal{C}^\otimes$.

**Example 4.4.3.6.** In the situation of Lemma 4.4.3.5, suppose that the condition stated in (1) is always satisfied. Moreover, we can construct an operadic $q$-left Kan extension of $F_0$ by setting $F = F_0 \circ v_{\alpha}$.

We now discuss the process of operadic left Kan extension along a correspondence $\text{Tens}^\otimes_{\alpha}$, where $\alpha$ is a face map in $\Delta$.

**Notation 4.4.3.7.** For $0 \leq i \leq m$, we let $\alpha_i : [m-1] \rightarrow [m]$ be the $i$th face map (given by $\alpha(j) = \begin{cases} j & \text{if } j < i \\ j + 1 & \text{if } j > i \end{cases}$), so that $\alpha$ is an isomorphism from $[m-1]$ onto $\{0, \ldots, i-1, i+1, \ldots, m\} \subseteq [m]$.

If $0 < i < m$, then the commutative diagram

$$
\begin{array}{ccc}
[1] & \longrightarrow & \{i-1, i\} \\
\downarrow & & \downarrow \\
[2] & \longrightarrow & \{i-1, i, i+1\}
\end{array}
\quad
\alpha_i
\begin{array}{ccc}
\{i-1, i\} & \longrightarrow & [m-1] \\
\downarrow & & \downarrow \\
\{i-1, i, i+1\} & \longrightarrow & [m]
\end{array}
$$

determines a map of generalized $\infty$-operads $\xi : \text{Tens}^\otimes_{\alpha} \rightarrow \text{Tens}^\otimes_{\alpha_i}$.

**Lemma 4.4.3.8.** Let $0 \leq i \leq m$ and let $\alpha_i : [m-1] \rightarrow [m]$ be as in Notation 4.4.3.7. Let $q : \mathcal{C}^\otimes \rightarrow \mathcal{O}^\otimes$ be a fibration of $\infty$-operads, and suppose we are given a commutative diagram of generalized $\infty$-operads

$$
\begin{array}{ccc}
\text{Tens}^\otimes_{[m]} & \xrightarrow{F_0} & \mathcal{C}^\otimes \\
\downarrow & & \downarrow q \\
\text{Tens}^\otimes_{\alpha} & \xrightarrow{f} & \mathcal{O}^\otimes
\end{array}
$$

There exists a map $F$ as indicated in the diagram, which is an operadic $q$-left Kan extension of $F_0$, if and only if the following conditions are satisfied:

(a) For $j \in [m-1]$, there exists a morphism $F_0(a_{\alpha(j)}) \rightarrow B$ in $\mathcal{C}$ lying over the morphism $f(a_{\alpha(j)}) \rightarrow f(b_j)$ in $\mathcal{O}$, given by an operadic $q$-colimit diagram $\Delta^1 \rightarrow \mathcal{C}^\otimes$.

(b) For $0 < j < i$, there exists a morphism $F_0(m_{j-1,j}) \rightarrow N$ in $\mathcal{C}$ lying over the morphism $f(m_{j-1,j}) \rightarrow f(n_{j-1,j})$ in $\mathcal{O}$, given by an operadic $q$-colimit diagram $\Delta^1 \rightarrow \mathcal{C}^\otimes$.

(c) For $i < j < m$, there exists a morphism $F_0(m_{j,j+1}) \rightarrow N$ in $\mathcal{C}$ lying over the morphism $f(m_{j,j+1}) \rightarrow f(n_{j,j+1})$, given by an operadic $q$-colimit diagram $\Delta^1 \rightarrow \mathcal{C}^\otimes$. 
4.4. THE RELATIVE TENSOR PRODUCT

(d) If $0 < i < m$ and $\xi : \text{Tens}_s^\otimes \to \text{Tens}_b^\otimes$, is defined as in Notation 4.4.3.7, then the diagram

\[ \begin{array}{ccc} \text{Tens}_s^\otimes & \xrightarrow{F_0 \circ \xi} & \mathcal{C}^\otimes \\ \downarrow & & \downarrow q \\ \text{Tens}_b^\otimes & \xrightarrow{F \circ \xi} & \mathcal{O}^\otimes \end{array} \]

admits an extension as indicated, which is an operadic $q$-left Kan extension of $F_0 \circ \xi$.

Moreover, a map of generalized $\infty$-operads $F : \text{Tens}_b^\otimes$, making the above diagrams commute is an operadic $q$-left Kan extension if and only if the following conditions are satisfied:

(a') For $j \in [m - 1]$, the map $F(a_{\alpha(j)}) \to F(b_j)$ in $\mathcal{C}$ is given by an operadic $q$-colimit diagram $\Delta^1 \to \mathcal{C}^\otimes$.

(b') For $0 < j < i$, the map $F(m_{j-1,j}) \to F(n_{j-1,j})$ is given by an operadic $q$-colimit diagram $\Delta^1 \to \mathcal{C}^\otimes$.

(c') For $i < j < m$, the map $F(m_{j,j+1}) \to F(n_{j-1,j})$ is given by an operadic $q$-colimit diagram $\Delta^1 \to \mathcal{C}^\otimes$.

(d') If $0 < i < m$, then $F \circ \xi$ is an operadic $q$-left Kan extension of $F \circ \xi | \text{Tens}_s^\otimes$.

Proof. For every object $X \in \text{Tens}_{[m-1]}$, we let $\mathcal{D}(X)$ denote the fiber product

\[ \text{Tens}_{[m]}^\otimes \times \text{Tens}_b^\otimes \text{Tens}_s^\otimes \mathcal{C}^\otimes / X. \]

The objects of $\text{Tens}_{[m-1]}$ have the form $\{b_j\}_{0 \leq j < m}$ and $\{n_{j-1,j}\}_{0 < j < m}$. The desired result follows from Theorem 3.1.2.3 together with the following observations:

(a'') If $X = b_j$, then $\mathcal{D}(X)$ contains $a_{\alpha(j)}$ as a final object.

(b'') If $X = n_{j-1,j}$ for $0 < j < i$, then $\mathcal{D}(X)$ contains $m_{j-1,j}$ as a final object.

(c'') If $X = n_{j-1,j}$ for $i < j < m$, then $\mathcal{D}(X)$ contains $m_{j,j+1}$ as a final object.

(d'') If $0 < i < m$, then $\xi$ induces an isomorphism from $\text{Tens}_{[2]}^\otimes \times \text{Tens}_b^\otimes \text{Tens}_s^\otimes / m$ to $\mathcal{D}(m_{i-1,i})$.

Lemma 4.4.3.9. Let $q : \mathcal{C}^\otimes \to \text{Ass}^\otimes$ be a monoidal $\infty$-category. Assume that $\mathcal{C}^\otimes$ admits geometric realizations of simplicial objects and that the tensor product functor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves geometric realizations of simplicial objects separately in each variable. Let $p : \mathcal{X} \to N(\Delta)^{op}$ be defined as in Corollary 4.4.3.2 (applied to identity map $N(\Delta)^{op} \to N(\Delta)^{op}$). Then:

1. The map $p$ is a coCartesian fibration.

2. If $\alpha : [n] \to [m]$ is a morphism in $\Delta$ with convex image, then the associated functor

\[ \alpha^\otimes : \text{Alg}_{\text{Tens}_{[n]}^\otimes / \text{Ass}(\mathcal{C})} \to \text{Alg}_{\text{Tens}_{[m]}^\otimes / \text{Ass}(\mathcal{C})} \]

is given by composition with the map $v_\alpha$ of Remark 4.4.3.4.

3. If $\alpha_i : [m-1] \to [m]$ is the morphism in $\Delta$ described in Notation 4.4.3.7 for $0 < i < m$, then the associated functor $(\alpha_i)_* : X_{[m]} \to X_{[m-1]}$ is given by the composition

\[ X_{[m]} \simeq \text{Alg}_{\text{Tens}_{[m]}^\otimes / \text{Ass}(\mathcal{C})} \simeq \text{BMod}(\mathcal{C}) \times_{\text{Alg}(\mathcal{C})} \cdots \times_{\text{Alg}(\mathcal{C})} \text{BMod}(\mathcal{C}) \simeq \text{Alg}_{\text{Tens}_{[m-1]}^\otimes / \text{Ass}(\mathcal{C})} \simeq X_{[m-1]}. \]
Here the functor $T$ is given by applying the relative tensor product functor

$$\text{BMod}(\mathcal{C}) \times_{\text{Alg}(\mathcal{C})} \text{BMod}(\mathcal{C}) \to \text{BMod}(\mathcal{C})$$

to the $i$th and $(i+1)$st factors.

**Proof.** To prove (1), it will suffice to show that for every map $\alpha: [n] \to [m]$ in $\Delta$ and every $F_0 \in \text{Alg}_{\text{Tens_{op}}} / \text{Ass}(\mathcal{C})$, there exists an operadic $q$-left Kan extension $F \in \text{Alg}_{\text{Tens}_q} / \text{Ass}(\mathcal{C})$ of $F$ (Corollary 4.4.3.2). We can factor $\alpha$ as a composition

$$[n] \xrightarrow{\beta} [k] \to [k+1] \to \cdots \to [m-1] \to [m],$$

where $\beta$ has convex image and remaining maps are of the form $\alpha_i: [p-1] \to [p]$, where $0 < i < p$. Using Theorems 4.4.3.1 and 3.1.4.1, we can assume either that $\alpha = \beta$ or that $\alpha$ has the form $\alpha_i: [p-1] \to [p]$ for $0 < i < p$. In these cases, the desired result (and the more explicit description of the associated functor supplied by (2) and (3)) follow from Lemmas 4.4.3.5 and 4.4.3.8, respectively. ☐

**Definition 4.4.3.10.** If $\mathcal{C}^\otimes \to \text{Ass}^\otimes$ is as in Lemma 4.4.3.9, we will denote the simplicial set $X$ by $\text{BMod}(\mathcal{C})^\otimes$.

**Remark 4.4.3.11.** Let $\mathcal{C}^\otimes \to \text{Ass}^\otimes$ be as in Lemma 4.4.3.9, and let $p : \text{BMod}(\mathcal{C})^\otimes \to N(\Delta)^{op}$ be the associated coCartesian fibration. We have canonical isomorphisms

$$\text{BMod}(\mathcal{C})^\otimes_{[0]} \simeq \text{Alg}(\mathcal{C}) \quad \text{BMod}(\mathcal{C})^\otimes_{[1]} \simeq \text{BMod}(\mathcal{C}).$$

Using Proposition 4.4.1.11, we see that for each $n \geq 0$, the inclusions $[1] \simeq \{i-1, i\} \hookrightarrow [n]$ induce an equivalence of $\infty$-categories

$$\text{BMod}(\mathcal{C})^\otimes_{[n]} \to \text{BMod}(\mathcal{C})^\otimes_{[1]} \times_{\text{BMod}(\mathcal{C})^\otimes_{[0]}} \cdots \times_{\text{BMod}(\mathcal{C})^\otimes_{[0]}} \text{BMod}(\mathcal{C})^\otimes_{[1]}$$

$$\simeq \text{BMod}(\mathcal{C})^\otimes \times_{\text{Alg}(\mathcal{C})} \cdots \times_{\text{Alg}(\mathcal{C})} \text{BMod}(\mathcal{C}).$$

One can regard the coCartesian fibration $p$ as encoding the structure of an $(\infty, 2)$-category in which the objects are associative algebra objects of $\mathcal{C}$ and the morphisms from $A \in \text{Alg}(\mathcal{C})$ to $B \in \text{Alg}(\mathcal{C})$ are given by the $(\infty, 1)$-category $A\text{BMod}_B(\mathcal{C})$.

We now describe some applications of Lemma 4.4.3.9.

**Proposition 4.4.3.12.** Let $\mathcal{C}$ be a monoidal $\infty$-category and let $A$ be an associative algebra object of $\mathcal{C}$. Assume that $\mathcal{C}$ admits geometric realizations of simplicial objects and that the tensor product on $\mathcal{C}$ preserves geometric realizations of simplicial objects separately in each variable. Then the planar $\infty$-operad $\text{Mod}^A_{\text{Ass}}(\mathcal{C})^\otimes$ is a monoidal $\infty$-category. Moreover, the tensor product on $\text{Mod}^A_{\text{Ass}}(\mathcal{C})$ corresponds (under the equivalence $\text{Mod}^A_{\text{Ass}}(\mathcal{C}) \simeq A\text{BMod}_A(\mathcal{C})$ provided by Theorem 4.4.1.28) to the relative tensor product functor $\otimes_A : A\text{BMod}_A(\mathcal{C}) \times A\text{BMod}_A(\mathcal{C}) \to A\text{BMod}_A(\mathcal{C})$ described in §4.4.2.

**Remark 4.4.3.13.** In the situation of Proposition 4.4.3.12, the tensor product on $\text{Mod}^A_{\text{Ass}}(\mathcal{C})$ again preserves geometric realizations of simplicial objects separately in each variable (Corollary 4.4.2.15).

**Proof.** We wish to show that the forgetful functor $\text{Mod}^A_{\text{Ass}}(\mathcal{C})^\otimes \to \text{Ass}^\otimes$ is a coCartesian fibration. According to Corollary T.2.4.2.10, it will suffice to show that for every map $\sigma : \Delta^n \to \text{Ass}^\otimes$, the induced map $\text{Mod}^A_{\text{Ass}}(\mathcal{C})^\otimes \times_{\text{Ass}^\otimes} \Delta^n \to \Delta^n$ is a coCartesian fibration (in fact, we may assume that $n \leq 2$. Let $\text{Cut} : N(\Delta)^{op} \to \text{Ass}^\otimes$ be the functor of Construction 4.1.2.5. We observe that $\sigma$ factors as a composition $\Delta^n \to N(\Delta)^{op} \to \text{Ass}^\otimes$. It will therefore suffice to show that the pullback $\text{Mod}^A_{\text{Ass}}(\mathcal{C})^\otimes \times_{\text{Ass}^\otimes} N(\Delta)^{op} \to N(\Delta)^{op}$ is a coCartesian fibration. This follows from Theorem 4.4.1.28 and Lemma 4.4.3.9. ☐
4.4. THE RELATIVE TENSOR PRODUCT

Proposition 4.4.3.14 (Associativity of the Tensor Product). Let \( q : \mathcal{C}^\otimes \to \mathcal{A}ss^\otimes \) be a monoidal \( \infty \)-category. Assume that \( \mathcal{C}^\otimes \) admits geometric realizations of simplicial objects and that the tensor product functor \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations of simplicial objects separately in each variable. Let \( X : \mathcal{B}\text{Mod}(\mathcal{C}) \times_{\mathcal{A}\text{lg}(\mathcal{C})} \mathcal{B}\text{Mod}(\mathcal{C}) \to \mathcal{B}\text{Mod}(\mathcal{C}) \) be the relative tensor product functor. Then the diagram

\[
\begin{array}{ccc}
\mathcal{B}\text{Mod}(\mathcal{C}) \times_{\mathcal{A}\text{lg}(\mathcal{C})} \mathcal{B}\text{Mod}(\mathcal{C}) & \xrightarrow{\mathcal{B}\text{Mod}(\mathcal{C}) \times \text{id}} & \mathcal{B}\text{Mod}(\mathcal{C}) \times \mathcal{B}\text{Mod}(\mathcal{C}) \\
\downarrow & & \downarrow \\
\mathcal{B}\text{Mod}(\mathcal{C}) & \xrightarrow{T} & \mathcal{B}\text{Mod}(\mathcal{C})
\end{array}
\]

commutes up to canonical homotopy.

Proof. Using Lemma 4.4.3.9, we see that both functors are induced by operadic \( q \)-left Kan extension along the correspondence \( \text{Tens}_\beta^\otimes \), where \( \beta \) is the morphism \( [1] \simeq \{0, 3\} \to [3] \) in \( \Delta \).

Remark 4.4.3.15. In the situation of Proposition 4.4.3.14, suppose we are given a quintuple of algebra objects \( A, B, C, D, E \in \mathcal{A}\text{lg}(\mathcal{C}) \) and bimodules \( M \in \mathcal{A}\text{B}\text{Mod}_B(\mathcal{C}), N \in \mathcal{A}\text{B}\text{Mod}_C(\mathcal{C}), P \in \mathcal{A}\text{B}\text{Mod}_D(\mathcal{C}), \) and \( Q \in \mathcal{A}\text{B}\text{Mod}_E(\mathcal{C}) \). Proposition 4.4.3.14 supplies a diagram of equivalences

\[
(M \otimes_B N) \otimes_C (P \otimes_D Q) \cong (M \otimes_B N) \otimes_C (P \otimes_D Q)
\]

in the \( \infty \)-category \( \mathcal{A}\text{B}\text{Mod}_G(\mathcal{C}) \). This diagram commutes up to (canonical) homotopy: indeed, each of its terms can be canonically identified with the image of \( (M, N, P, Q) \in \mathcal{A}\text{lg}(\mathcal{C}) \) under the functor \( \mathcal{A}\text{B}\text{Mod}_G(\mathcal{C}) \to \mathcal{B}\text{Mod}(\mathcal{C}) \) given by operadic \( q \)-left Kan extension along \( \text{Tens}_\beta^\otimes \), where \( \beta \) is the morphism \( [1] \simeq \{0, 4\} \to [4] \) in \( \Delta \). In fact, the coCartesian fibration \( q : X \to N(\Delta_\ast)^\text{op} \) can be regarded as witnessing the fact that the relative tensor product operation on bimodules is associative up to coherent homotopy.

Proposition 4.4.3.16 (Unitality of the Tensor Product). Let \( q : \mathcal{C}^\otimes \to \mathcal{A}ss^\otimes \) be a monoidal \( \infty \)-category. Assume that \( \mathcal{C}^\otimes \) admits geometric realizations of simplicial objects and that the tensor product functor \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations of simplicial objects separately in each variable. Let \( u : \mathcal{A}\text{lg}(\mathcal{C}) \to \mathcal{B}\text{Mod}(\mathcal{C}) \) be given by composition with the forgetful functor \( \mathcal{B}\text{Mod}(\mathcal{C}) \to \mathcal{A}ss^\otimes \) (so that \( u \) carries an algebra object \( A \in \mathcal{A}\text{lg}(\mathcal{C}) \) to the underlying object of \( \mathcal{C} \), regarded as an \( A \)-\( A \)-bimodule), and let \( T : \mathcal{B}\text{Mod}(\mathcal{C}) \times_{\mathcal{A}\text{lg}(\mathcal{C})} \mathcal{B}\text{Mod}(\mathcal{C}) \to \mathcal{B}\text{Mod}(\mathcal{C}) \) be the relative tensor product functor. Then the composite functors

\[
\begin{align*}
\mathcal{B}\text{Mod}(\mathcal{C}) & \simeq \mathcal{A}\text{lg}(\mathcal{C}) \times_{\mathcal{A}\text{lg}(\mathcal{C})} \mathcal{B}\text{Mod}(\mathcal{C}) \xrightarrow{u \times \text{id}} \mathcal{B}\text{Mod}(\mathcal{C}) \times_{\mathcal{A}\text{lg}(\mathcal{C})} \mathcal{B}\text{Mod}(\mathcal{C}) \xrightarrow{T} \mathcal{B}\text{Mod}(\mathcal{C}) \\
\mathcal{B}\text{Mod}(\mathcal{C}) & \simeq \mathcal{B}\text{Mod}(\mathcal{C}) \times_{\mathcal{A}\text{lg}(\mathcal{C})} \mathcal{A}\text{lg}(\mathcal{C}) \xrightarrow{\text{id} \times \eta} \mathcal{B}\text{Mod}(\mathcal{C}) \times_{\mathcal{A}\text{lg}(\mathcal{C})} \mathcal{B}\text{Mod}(\mathcal{C}) \xrightarrow{T} \mathcal{B}\text{Mod}(\mathcal{C})
\end{align*}
\]

are canonically homotopic to the identity.
We can state Proposition 4.4.3.16 more informally as follows: if $M$ is an $A$-$B$-bimodule object of $\mathcal{C}$, then we have canonical equivalences

$$A \otimes_A M \simeq M \simeq M \otimes_B B.$$

Proof. Apply Lemma 4.4.3.9 to the commutative diagrams

$$\alpha \downarrow \downarrow \beta$$

in $\Delta$, where $\alpha$ is the inclusion $[1] \simeq \{0, 2\} \to [2]$ and $\beta$ is a left inverse to $\alpha$.

Remark 4.4.3.17. In the situation of Proposition 4.4.3.16, if we are given a pair of bimodule objects $M \in {}_A \text{BMod}_B(\mathcal{C})$ and $N \in {}_B \text{BMod}_C(\mathcal{C})$, then the diagrams

$$A \otimes_A (M \otimes_B N) \to (A \otimes_A M) \otimes_B C \leftarrow M \otimes_B N$$

$$[M \otimes_B N] \otimes_C C \to M \otimes_B (N \otimes_C C) \leftarrow M \otimes_B N$$

$$[M \otimes_B B] \otimes_B N \to M \otimes_B (B \otimes_B N) \leftarrow M \otimes_B N$$

in the $\infty$-category ${}_A \text{BMod}_C(\mathcal{C})$ commute up to canonical homotopy.

Remark 4.4.3.18. In the situation of Proposition 4.4.3.16, let $A$ be an associative algebra object of $\mathcal{C}$, and regard $A$ as a bimodule over itself. For any $M \in {}_A \text{BMod}_A(\mathcal{C})$, Proposition 4.4.3.16 supplies equivalences

$$\phi : A \otimes_A M \simeq M \quad \psi : M \otimes_A A \simeq M.$$

When $M = A$, the maps $\phi$ and $\psi$ are canonically homotopic. Indeed, both are determined the object of $\text{Alg}_{\text{Tens}}/\text{Ass}(\mathcal{C})$ given by the composition

$$\text{Tens}_\circ \to \text{Ass}_\circ \overset{A}{\to} \mathcal{C}_\circ.$$

We conclude this section by giving the proof of Theorem 4.4.3.1. First, we need some preliminaries.

Lemma 4.4.3.19. Let $S$ and $T$ be finite linearly ordered sets, where $T$ is nonempty. Let $\mathcal{C}$ be the category whose objects are linearly ordered sets $\bar{S}$ equipped with monotone maps

$$S \leftarrow \bar{S} \overset{\alpha}{\to} T$$

such that $\alpha$ is surjective. Then $N(\mathcal{C})$ is weakly contractible.
Proof. We work by induction on the number of elements of \( S \). If \( S \) is empty, then the result is obvious. Otherwise, \( S \) has a smallest element \( s \). Let \( \mathcal{D} \) be the category whose objects are nonempty linearly ordered sets \( T \) equipped with a map \( \gamma : \mathcal{T} \to T \), and let \( f : \mathcal{C} \to \mathcal{D} \) be the functor given by \( \bar{S} \mapsto \alpha^{-1}\{s\} \). We observe that \( f \) induces a Cartesian fibration \( N(\mathcal{C}) \to N(\mathcal{D}) \). Moreover, if \( \gamma : \mathcal{T} \to T \) is an object of \( \mathcal{D} \) and \( t_0 \in T \) is the largest element in \( \gamma(\mathcal{T}) \), then the fiber of \( f \) over \( \gamma \) can be identified with the category \( \mathcal{C}' \) whose objects are diagrams

\[
S - \{s\} \xrightarrow{\alpha'} \bar{S}' \xrightarrow{\beta'} \{t \in T : t \geq t_0\}
\]

such that \( \alpha' \) is surjective. The inductive hypothesis guarantees that \( \mathcal{C}' \) has a weakly contractible nerve, so that Lemma T.4.1.3.2 guarantees that the map \( N(\mathcal{C}) \to N(\mathcal{D}) \) is left cofinal (and therefore a weak homotopy equivalence). It will therefore suffice to show that \( N(\mathcal{D}) \) is weakly contractible. This is clear, since \( \mathcal{D} \) has a final object (given by the identity map \( T \to T \)).

Lemma 4.4.3.20. Fix maps of finite linearly ordered sets \( \mu : S \to T \), \( \nu : S \to S' \), where \( \mu \) is injective. Let \( \mathcal{C}_{\mu, \nu} \) be the category whose objects are commutative diagrams of finite linearly ordered sets

\[
\begin{array}{ccc}
S & \xrightarrow{\mu} & T \\
\downarrow{\nu} & & \downarrow \\
S' & \xrightarrow{\mu'} & T',
\end{array}
\]

where \( \mu' \) is injective. Then the nerve \( N(\mathcal{C}_{\mu, \nu}) \) is weakly contractible.

Proof. Let \( \mathcal{C}_{\mu, \nu}^0 \) be the full subcategory of \( \mathcal{C}_{\mu, \nu} \) spanned by those diagrams which induce a surjection \( T \coprod S' \to T' \). It is easy to see that the inclusion \( \mathcal{C}_{\mu, \nu}^0 \subseteq \mathcal{C}_{\mu, \nu} \) admits a right adjoint. It will therefore suffice to show that the simplicial set \( N(\mathcal{C}_{\mu, \nu}^0) \) is weakly contractible.

We work by induction on the number of elements of the set \( T - \mu(S) \). If \( T = \mu(S) \), then \( \mathcal{C}_{\mu, \nu}^0 \) has an initial object (characterized by the requirement that \( \mu' \) be a bijection) and the result is obvious. If \( T - \mu(S) \) is nonempty, then we can factor \( \mu \) as a composition of injective maps

\[
S \xrightarrow{\mu_0} U \xrightarrow{\mu_1} T,
\]

where \( U - \mu_0(S) \) consists of a single element \( u \), and \( \mu_1 \) is a monomorphism. Let \( \mathcal{D} \) be the category whose objects are commutative diagrams

\[
\begin{array}{ccc}
S & \xrightarrow{\mu_0} & U \\
\downarrow{\nu} & & \downarrow{\mu_1} \\
S' & \xrightarrow{\mu_0'} & U' \xrightarrow{\mu_1'} T',
\end{array}
\]

where \( \mu_0' \) and \( \mu_1' \) are injective and the maps \( U \coprod S' \to U' \) and \( T \coprod U' \to T' \) are surjective. There is an evident forgetful functor \( \mathcal{D} \to \mathcal{C}_{\mu_0, \nu}^0 \). This functor has a right adjoint and therefore induces a weak homotopy equivalence \( N(\mathcal{D}) \to N(\mathcal{C}_{\mu_0, \nu}) \); it will therefore suffice to show that \( \mathcal{D} \) is weakly contractible. We have another forgetful functor \( \mathcal{D} \to \mathcal{C}_{\mu_0, \nu}^0 \), which induces a Cartesian fibration \( \phi : N(\mathcal{D})^{op} \to N(\mathcal{C}_{\mu_0, \nu})^{op} \). Each fiber of \( \phi \) is equivalent to an \( \infty \)-category of the form \( N(\mathcal{C}_{\mu_0, \nu})^{op} \) for some map \( \nu' : U \to U' \), and is therefore weakly contractible by the inductive hypothesis. Lemma T.4.1.3.2 implies that \( \phi \) is left cofinal and therefore a weak homotopy equivalence. We are therefore reduced to proving that the simplicial set \( N(\mathcal{C}_{\mu_0, \nu}^0) \) is weakly contractible. We may therefore replace \( \mu \) by \( \mu_0 \) and thereby reduce to the case where \( T - \mu(S) \) consists of a single element, which we will again denote by \( u \).

Let \( S_- = \{s \in S : \mu(s) < u\} \) and \( S_+ = \{s \in S : \mu(s) > u\} \). We will assume for simplicity that \( S_- \) and \( S_+ \) are nonempty (the cases where either \( S_- \) or \( S_+ \) require slight modifications). Then \( S_- \) has a largest element \( s_- \), and \( S_+ \) has a largest element \( s_+ \). Let \( S'_0 = \{s' \in S' : \nu(s_-) \leq s' \leq \nu(s_+)\} \). As an ordered set,
we can write \( S' = \{ \nu_s = s_0 < s_1' < \cdots < s_n' = \nu(s_+) \} \). For \( 0 \leq i \leq n \), let \( X_i \) denote the object of \( \mathcal{C}_{\mu,\nu} \) corresponding to the diagram

\[
\begin{array}{ccc}
S & \xrightarrow{\mu} & T \\
\downarrow{\nu} & & \downarrow{\nu'} \\
S' & \xrightarrow{\mu'} & S''
\end{array}
\]

where \( \nu'(u) = i \). For \( 1 \leq i \leq n \), let \( Y_i \) denote the object of \( \mathcal{C}_{\mu,\nu} \) corresponding to the diagram

\[
\begin{array}{ccc}
S & \xrightarrow{\mu} & T \\
\downarrow{\nu} & & \downarrow{\nu'} \\
S' & \xrightarrow{\mu'} & S' \cup \{ u' \},
\end{array}
\]

where \( \nu'(u) = u' \) and the ordering on \( S' \cup \{ u' \} \) is such that \( u \leq s' \) if and only if \( s'_i \leq s'. \) It is easy to see that every object of \( \mathcal{C}_{\mu,\nu} \) is uniquely isomorphic either to \( X_i \) (for some \( 0 \leq i \leq n \)) or \( Y_i \) (for some \( 1 \leq i \leq n \)); moreover, \( \mathcal{C}_{\mu,\nu} \) is equivalent to the category depicted by the diagram

\[
X_0 \xhookrightarrow{Y_1} X_1 \xhookrightarrow{Y_2} \cdots \xhookrightarrow{Y_n} X_n.
\]

It follows that the geometric realization \( |N(\mathcal{C}_{\mu,\nu})| \) is homeomorphic to a closed interval and is therefore contractible, as desired. \( \square \)

**Proposition 4.4.3.21.** The forgetful functor \( N(\text{Step}) \to N(\Delta)^{\text{op}} \) is a flat categorical fibration (see Definition B.3.8).

**Proof.** We will prove that the map \( N(\text{Step})^{\text{op}} \to N(\Delta) \) is flat. Fix a 2-simplex \( \sigma \) of \( N(\Delta) \), corresponding to a composable pair of morphisms \( [k] \xrightarrow{\alpha} [k'] \xrightarrow{\beta} [k''] \) in \( \Delta \). Let \( \mathcal{C} = N(\text{Step})^{\text{op}} \times_{N(\text{Fin}_\Delta)} \Delta^2 \); for \( i \in \{0, 1, 2\} \) we let \( \mathcal{C}_i \) denote the fiber product \( \mathcal{C} \times_{\Delta^2} \{i\} \). Fix a morphism \( f : X \to Z \) in \( \mathcal{C} \), where \( X \in \mathcal{C}_0 \) and \( Z \in \mathcal{C}_2 \), and let \( \mathcal{D} = \mathcal{C}_1 \times_{\mathcal{C}} \mathcal{C}_{X/Z} \); we wish to show that \( \mathcal{D} \) is weakly contractible. We can identify \( X \) with a morphism \( \gamma : [n] \to [k] \) and \( Z \) with a morphism \( \gamma'' : [n''] \to [k''] \), so that an object of \( \mathcal{D} \) corresponds to a commutative diagram

\[
\begin{array}{ccc}
[n] & \xrightarrow{\beta} & [n''] \\
\downarrow{\gamma} & & \downarrow{\gamma''} \\
[k] & \xrightarrow{\alpha} & [k']
\end{array}
\]

in \( \Delta \), where \( \gamma'(n') \) is a convex subset of \([k']\).

Let \( \mathcal{S} \subseteq [k'] \) be the smallest convex subset of \([k']\) which contains \((\beta \circ \gamma)([n])\), and let \( S = \mathcal{S} \cap \beta([n]) \). Let \( \mathcal{D}' \) be the full subcategory of \( \mathcal{D} \) spanned by diagrams with the following property that \([n'] = \alpha([n]) \cup \gamma'^{-1} \mathcal{S} \). It is not difficult to see that the inclusion \( \mathcal{D}' \subseteq \mathcal{D} \) admits a right adjoint, and is therefore a weak homotopy equivalence. It will therefore suffice to show that \( \mathcal{D}' \) is weakly contractible.

Let \( T = \beta(S) \subseteq [k''] \), and let \( \mathcal{T} = \gamma''^{-1} T \subseteq [n''] \). Note that \( T \) is contained in the smallest convex subset of \([k'']\) which contains the image of the map \([n] \to [k] \to [k'] \to [k'']\). Since the image of \( \gamma'' \) is convex, we conclude that \( \gamma'' \) induces a surjection \( \mathcal{T} \to T \). Unwinding the definitions, we see that the construction \([n'] \mapsto \gamma'^{-1} \mathcal{S} \) determines an equivalence from \( \mathcal{D}' \) to the nerve of the category whose objects are linearly ordered sets \( S \) which fit into a commutative diagram

\[
\begin{array}{ccc}
S & \xrightarrow{\delta} & \mathcal{T} \\
\downarrow{\beta} & & \downarrow{\gamma''} \\
S & \xrightarrow{\alpha} & [k'i]
\end{array}
\]
4.5. MODULES OVER COMMUTATIVE ALGEBRAS 423

where $\delta$ is surjective. We now conclude by observing that this category is equivalent to a product, over the elements of $T$, of categories of the type described in Lemma 4.4.3.19 (and therefore has a weakly contractible nerve).

Remark 4.4.3.22. Suppose we are given a morphism $(n', k', c'_-, c'_+) \to (n, k, c_-, c_+)$ in $\text{Tens}^\otimes$, corresponding to a nondecreasing map of linearly ordered sets $\lambda : [k] \to [k']$ and a morphism $\alpha : (n') \to (n)$ in $\text{Ass}^\otimes$. For $1 \leq i \leq n$, let $L_i = \{j_1 < j_2 < \cdots < j_p\}$ denote the inverse image $\alpha^{-1}\{i\}$, regarded as a linearly ordered set. For $\lambda c_-(i) < m \leq \lambda c_+(i)$, there is a unique element $\mu_i(m) \in L_i$ such that $c'_-(\mu_i(m)) = m - 1$ and $c'_+\mu_i(m)) = m$. The function $\mu_i$ determines an injective map of linearly ordered sets $\{\lambda c_-(i) + 1, \ldots, \lambda c_+(i)\} \to L_i$.

Conversely, suppose we are given an object $(n, k, c_-, c_+)$ in $\text{Tens}^\otimes$ and a morphism $\lambda : [k] \to [k']$ in $\Delta$. Given any collection of injective maps of finite linearly ordered sets

$$\mu_i : \{\lambda c_-(i) + 1, \ldots, \lambda c_+(i)\} \to L_i$$

for $1 \leq i \leq n$, we can reconstruct a morphism $(n', k', c'_-, c'_+) \to (n, k, c_-, c_+)$ covering $\lambda$, which is unique up to canonical isomorphism.

Proof of Theorem 4.4.3.1. Fix a 2-simplex $\sigma$ of $N(\Delta)^\text{op}$ corresponding to a composable pair of morphisms $[k] \xrightarrow{\lambda} [k'] \xrightarrow{\mu} [k'']$ in $\Delta$. Let $\mathcal{C} = \text{Tens}^\otimes \times_{N(\Delta)^\text{op}} \Delta^2$, and let $\mathcal{C}_i = \mathcal{C} \times_{\Delta^2} \{i\}$ for $i \in \{0, 1, 2\}$. Fix a map $f : X \to Z$ in $\mathcal{C}$ where $X = ((n''), [k''], c''_-, c''_+)$ and $Z = ((n), [k], c_-, c_+)$ in $\mathcal{C}_{01}$. We wish to prove that the simplicial set $\mathcal{D} = \mathcal{C}_{X/Z} \times_{\Delta^2} \{1\}$ is weakly contractible. According to Remark 4.4.3.22, we can identify $f$ with a collection of finite linearly ordered sets $L_i$ equipped with injective monotone maps $\mu_i : \{\lambda' c_-(i) + 1, \ldots, \lambda' c_+(i)\} \to L_i$ for $1 \leq i \leq n$. Similarly, we can identify an object of $\mathcal{D}$ with a collection of commutative diagrams of finite linearly ordered sets

$$\begin{array}{ccc}
\{\lambda' c_-(i) + 1, \ldots, \lambda' c_+(i)\} & \xrightarrow{\nu_i} & L_i \\
\downarrow \mu_i & & \downarrow \\
\{\lambda c_-(i) + 1, \ldots, \lambda c_+(i)\} & \xrightarrow{\nu'_i} & L'_i
\end{array}$$

defined for $1 \leq i \leq n$, where $\mu'_i$ is injective and the map $\nu_i$ is characterized by the inequalities

$$\lambda'(\nu_i(m) - 1) \leq m - 1 < m \leq \lambda'(\nu_i(m)).$$

It follows that $\mathcal{D}$ equivalent to a finite product of (the nerves) of categories of the type described in Lemma 4.4.3.20, and is therefore weakly contractible.

4.5 Modules over Commutative Algebras

This section is devoted to the study of algebras and modules over the commutative $\infty$-operad $\text{Comm}^\otimes = N(\text{Fin}_*)$ of Example 2.1.1.18. Our principal results can be summarized as follows:

1. Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category and let $\text{CAlg}(\mathcal{C})$ be the $\infty$-category of commutative algebra objects of $\mathcal{C}$. Since $\text{Comm}^\otimes$ is a coherent $\infty$-operad (Example 3.3.1.12), we can associate to each commutative algebra object $A \in \text{CAlg}(\mathcal{C})$ an $\infty$-operad $\text{Mod}_A^{\text{Comm}}(\mathcal{C})$. In §4.5.1, we will show that the underlying $\infty$-category $\text{Mod}_A^{\text{Comm}}(\mathcal{C})$ is equivalent to the $\infty$-category $\text{LMod}_A(\mathcal{C})$ of left $A$-module objects of $\mathcal{C}$ studied in §4.2 (Proposition 4.5.1.4); here we abuse notation by identifying $A$ with the underlying associative algebra object of $\mathcal{C}$ (that is, the image of $A$ under the forgetful functor $\text{CAlg}(\mathcal{C}) \to \text{Alg}(\mathcal{C})$).
4.5.1 Left and Right Modules over Commutative Algebras

Let $R$ be an associative ring. We can associate to $R$ a category $LMod_R$ of left $R$-modules and a category $RMod_R$ of right $R$-modules. If $R$ is commutative, then these categories are equivalent to one another: every left action of $R$ on an abelian group $M$ can also be viewed as a right action of $R$ on $M$. In this section, we will describe an $\infty$-categorical analogue of this phenomenon. Suppose that $A$ is a commutative algebra object in $CAlg(C)$ and any coherent $\infty$-category $\mathcal{C}$, and let us abuse notation by identifying $A$ with its image in $\text{Alg}(\mathcal{C})$. We will show that there is a canonical equivalence $LMod_A(\mathcal{C}) \simeq RMod_A(\mathcal{C})$. In fact, both of these $\infty$-categories are equivalent to the (symmetrically defined) $\infty$-category $\text{Mod}^\text{Comm}_A(\mathcal{C})$ introduced in §3.3.3.

In what follows, it will be convenient to introduce a slight simplification in notation:

**Definition 4.5.1.1.** Let $\mathcal{O}^\otimes \to N(\mathcal{F}_{\text{Fin}})$ be a generalized $\infty$-operad. We let $\text{Mod}(\mathcal{O})^\otimes$ denote the generalized $\infty$-operad $\text{Mod}^\text{Comm}(\mathcal{O})^\otimes$ of Definition 3.3.3.8. If $A \in CAlg(\mathcal{C})$, we let $\text{Mod}_A(\mathcal{O})^\otimes$ denote the $\infty$-operad $\text{Mod}(\mathcal{O})^\otimes \times_{CAlg(\mathcal{C})} \{A\}$, and $A\text{Mod}(\mathcal{O})$ its underlying $\infty$-category.

**Remark 4.5.1.2.** Let $f : \mathcal{O}'^\otimes \to \mathcal{O}^\otimes$ be a map of coherent $\infty$-operads, and let $\mathcal{C}^\otimes \to \mathcal{O}^\otimes$ be a fibration of generalized $\infty$-operads. We let $\text{Mod}^{\mathcal{O}'}(\mathcal{C})^\otimes$ denote the $\infty$-category $\text{Mod}^{\mathcal{O}'}(\mathcal{C})^\otimes$, where $\mathcal{C}^\otimes = \mathcal{C}^\otimes \times_{\mathcal{O}^\otimes} \mathcal{O}^\otimes$.

The map $f$ induces a map $F : \mathcal{K}_{\mathcal{O}'} \to \mathcal{K}_{\mathcal{O}} \times_{\mathcal{O}^\otimes} \mathcal{O}^\otimes$. Composition with $F$ determines a functor

$$\text{Mod}^{\mathcal{O}'}(\mathcal{C})^\otimes \times_{\mathcal{O}^\otimes} \mathcal{O}^\otimes \to \text{Mod}^{\mathcal{O}'}(\mathcal{C})^\otimes.$$

In particular, for any generalized $\infty$-operad $\mathcal{C}^\otimes$ and any coherent $\infty$-operad $\mathcal{O}$, we have a canonical map

$$\text{Mod}(\mathcal{C})^\otimes \times_{N(\mathcal{F}_{\text{Fin}})} \mathcal{O}^\otimes \to \text{Mod}^{\mathcal{O}}(\mathcal{C})^\otimes.$$

**Construction 4.5.1.3.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad. Applying Remark 4.5.1.2 to the $\infty$-operad $\text{Ass}^\otimes$, we obtain a forgetful functor $\theta : \text{Mod}(\mathcal{O}) \to \text{Mod}^{\text{Ass}}(\mathcal{O})$. Let $\text{Bin}'(\mathcal{O})$ be defined as in Construction 4.4.1.24 (applied to the planar $\infty$-operad $\mathcal{O}^\otimes \times_{N(\mathcal{F}_{\text{Fin}})} \text{Ass}^\otimes$) and let $\text{Bin}'(\mathcal{O})[1]$ denote the fiber $\text{Bin}'(\mathcal{O}) \times_{N(\Delta)} \{[1]\}$, so that Theorem 4.4.1.28 supplies an equivalence $\text{Mod}^{\text{Ass}}(\mathcal{O}) \to \text{Alg}(\mathcal{C}) \times_{\Delta Alg(\mathcal{C})} \text{Alg}(\mathcal{C}) \text{Bin}'(\mathcal{O})[1]$. Let $\Delta LMod(\mathcal{O})$ be defined as in Definition 4.2.2.10 (where we view the $\infty$-category $\mathcal{C}$ as weakly enriched over itself), so
4.5. MODULES OVER COMMUTATIVE ALGEBRAS

there is an evident forgetful functor $\text{Bim}'(\mathcal{E})_{[1]} \to \Delta \text{LMod}(\mathcal{E})$. Composing these functors, we obtain a map $\Theta : \text{Mod}(\mathcal{E}) \to \Delta \text{LMod}(\mathcal{E})$. We observe that $\Theta$ fits into a commutative diagram

\[
\begin{array}{ccc}
\text{Mod}(\mathcal{E}) & \longrightarrow & \Delta \text{LMod}(\mathcal{E}) \\
\downarrow & & \downarrow \\
\text{CAlg}(\mathcal{E}) & \longrightarrow & \Delta \text{Alg}(\mathcal{E}).
\end{array}
\]

The main result of this section can now be stated as follows:

**Proposition 4.5.1.4.** Let $\mathcal{E}^\otimes \to N(\text{Fin}_*)$ be an $\infty$-operad. Then Construction 4.5.1.3 determines a homotopy pullback diagram of $\infty$-categories

\[
\begin{array}{ccc}
\text{Mod}(\mathcal{E}) & \longrightarrow & \Delta \text{LMod}(\mathcal{E}) \\
\downarrow & & \downarrow \\
\text{CAlg}(\mathcal{E}) & \longrightarrow & \Delta \text{Alg}(\mathcal{E}).
\end{array}
\]

**Corollary 4.5.1.5.** Let $\mathcal{E}^\otimes$ be an $\infty$-operad, let $A \in \text{CAlg}(\mathcal{E})$, and let us abuse notation by identifying $A$ with its image under the forgetful functor $\text{CAlg}(\mathcal{E}) \to \text{Alg}(\mathcal{E}) \to \Delta \text{Alg}(\mathcal{E})$. Then the functor $\Theta$ of Construction 4.5.1.3 induces an equivalence of $\infty$-categories $\text{Mod}_A(\mathcal{E}) \to \Delta \text{LMod}_A(\mathcal{E})$.

**Corollary 4.5.1.6.** Let $\mathcal{E}^\otimes$ be an $\infty$-operad. Then $\text{Mod}(\mathcal{E})$ can be identified with the homotopy fiber product of $\infty$-categories $\text{LMod}(\mathcal{E}) \times_{\text{Alg}(\mathcal{E})} \text{CAlg}(\mathcal{E})$. If $A \in \text{CAlg}(\mathcal{E})$, there is a canonical equivalence of $\infty$-categories $\text{Mod}_A(\mathcal{E}) \simeq \text{LMod}_A(\mathcal{E})$ (here we abuse notation by identifying $A$ with its image in $\text{Alg}(\mathcal{E})$).

**Proof.** Consider the functor $\Phi : \Delta^\text{op} \times [1] \to (\text{Fin}_*)_{(1)}/$ described as follows:

- For $n \geq 0$, we have $\Phi([n], 0) = (\alpha : (1) \to \psi([n] \ast [0]))$, where $\psi$ denotes the composition of the functor $\phi : \Delta^\text{op} \to \text{Ass}^\otimes$ with the forgetful functor $\text{Ass}^\otimes \to \text{Fin}_*$ and $\alpha : (1) \to \psi([n] \ast [0])$ carries $1 \in (1)$ to the point $[n] \in \psi([n] \ast [0])$.
- For $n \geq 0$, we have $\Phi([n], 1) = (\alpha : (1) \to \psi([n]))$, where $\alpha$ is the null morphism given by the composition $(1) \to ([0]) \to \psi([n]) \simeq [n]$.

Let $\mathcal{J}_0$ denote the full subcategory of $(\text{Fin}_*)_{(1)}/$ spanned by the semi-inert morphisms $(1) \to (n)$. We observe that $\Phi$ defines a functor $\Delta^\text{op} \times [1] \to \mathcal{J}_0$. Let $\mathcal{J}$ denote the categorical mapping cylinder of the functor $\Phi$. More precisely, the category $\mathcal{J}$ is defined as follows:

- An object of $\mathcal{J}$ is either an object $\alpha : (1) \to (n)$ of $\mathcal{J}_0$ or an object $([n], i)$ of $\Delta^\text{op} \times [1]$.
- Morphisms in $\mathcal{J}$ are defined as follows:

  \[
  \text{Hom}_\mathcal{J}(\alpha, \alpha') = \text{Hom}_{\mathcal{J}_0}(\alpha, \alpha') \\
  \text{Hom}_\mathcal{J}(([n], i), ([n'], i')) = \text{Hom}_{\Delta^\text{op} \times [1]}/((n), i), ([n'], i')) \\
  \text{Hom}_\mathcal{J}(([n], i), \alpha) = \emptyset.
  \]

The full subcategory of $\mathcal{J}_{\text{Comm}} \times_{\text{Comm}^\otimes} (1)$ spanned by the null morphisms $(1) \to (n)$ is actually isomorphic (rather than merely equivalent) to $\text{Comm}^\otimes$. Consequently, we have an isomorphism $\text{Mod}^\text{Comm}(\mathcal{E}) \simeq \text{Mod}^\text{Comm}(\mathcal{E})$, where the latter can be identified with a full subcategory of $\text{Fun}^\text{Comm}^\otimes(N(\mathcal{J}), \mathcal{E}^\otimes)$. We regard $N(\mathcal{J})$ as equipped with a forgetful functor to $\text{Comm}^\otimes$. Let $\mathcal{D}$ denote the full subcategory of $\text{Fun}^\text{Comm}^\otimes(N(\mathcal{J}), \mathcal{E}^\otimes)$ spanned by those functors $F$ which satisfy the following conditions:

- An object of $\mathcal{J}$ is either an object $\alpha : (1) \to (n)$ of $\mathcal{J}_0$ or an object $([n], i)$ of $\Delta^\text{op} \times [1]$.
- Morphisms in $\mathcal{J}$ are defined as follows:

  \[
  \text{Hom}_\mathcal{J}(\alpha, \alpha') = \text{Hom}_{\mathcal{J}_0}(\alpha, \alpha') \\
  \text{Hom}_\mathcal{J}(([n], i), ([n'], i')) = \text{Hom}_{\Delta^\text{op} \times [1]}/((n), i), ([n'], i')) \\
  \text{Hom}_\mathcal{J}(([n], i), \alpha) = \emptyset.
  \]

The full subcategory of $\mathcal{K}_{\text{Comm}} \times_{\text{Comm}^\otimes} (1)$ spanned by the null morphisms $(1) \to (n)$ is actually isomorphic (rather than merely equivalent) to $\text{Comm}^\otimes$. Consequently, we have an isomorphism $\text{Mod}^\text{Comm}(\mathcal{E}) \simeq \text{Mod}^\text{Comm}(\mathcal{E})$, where the latter can be identified with a full subcategory of $\text{Fun}^\text{Comm}^\otimes(N(\mathcal{J}), \mathcal{E}^\otimes)$. We regard $N(\mathcal{J})$ as equipped with a forgetful functor to $\text{Comm}^\otimes$, given by composing the retraction $r : \mathcal{J} \to \mathcal{J}_0$ with the forgetful functor $N(\mathcal{J}_0) \to \text{Comm}^\otimes$. Let $\mathcal{D}$ denote the full subcategory of $\text{Fun}^\text{Comm}^\otimes(N(\mathcal{J}), \mathcal{E}^\otimes)$ spanned by those functors $F$ which satisfy the following conditions:

- An object of $\mathcal{J}$ is either an object $\alpha : (1) \to (n)$ of $\mathcal{J}_0$ or an object $([n], i)$ of $\Delta^\text{op} \times [1]$.
- Morphisms in $\mathcal{J}$ are defined as follows:

  \[
  \text{Hom}_\mathcal{J}(\alpha, \alpha') = \text{Hom}_{\mathcal{J}_0}(\alpha, \alpha') \\
  \text{Hom}_\mathcal{J}(([n], i), ([n'], i')) = \text{Hom}_{\Delta^\text{op} \times [1]}/((n), i), ([n'], i')) \\
  \text{Hom}_\mathcal{J}(([n], i), \alpha) = \emptyset.
  \]
(i) The restriction of $F$ to $N(\mathcal{J}_0)$ belongs to $\text{Mod}^\text{Comm}(\mathcal{C})$.

(ii) For every object $([n], i) \in \Delta^{op} \times [1]$, the canonical map $F(\Phi([n], i)) \to F([n], i)$ is an equivalence in $\mathcal{C}^\otimes$ (equivalently: $F$ is a $p$-left Kan extension of $F|N(\mathcal{J}_0)$).

Let $\mathcal{J}'$ denote the full subcategory of $\mathcal{J}$ spanned by those objects corresponding to null morphisms $\langle 1 \rangle \to \langle n \rangle$ in $\mathcal{F}\text{in}_*$ or having the form $\alpha : \langle 1 \rangle \to \langle n \rangle$ where $\alpha$ is null, or pairs $([n], i) \in \Delta^{op} \times [1]$ where $i = 1$. Let $\mathcal{D}'$ denote the full subcategory of $\text{Fun}_{\text{Comm}}^\otimes(N(\mathcal{J}'), \mathcal{C}^\otimes)$ spanned by those functors $F$ satisfying the following conditions:

(i') The restriction of $F$ to $N(\mathcal{J}_0 \cap \mathcal{J}')$ belongs to $\text{CAlg}(\mathcal{C})$.

(ii') For $n \geq 0$, the canonical map $F(\Phi([n], 1)) \to F([n], 1)$ is an equivalence in $\mathcal{C}^\otimes$ (equivalently: $F$ is a $p$-left Kan extension of $F|N(\mathcal{J}_0 \cap \mathcal{J}')$).

Using Proposition T.4.3.2.15, we deduce that inclusion $\mathcal{J}_0 \hookrightarrow \mathcal{J}$ induces a trivial Kan fibrations

$$\mathcal{D} \to \text{Mod}^\text{Comm}(\mathcal{C}) \quad \mathcal{D}_0 \to \text{CAlg}(\mathcal{C}).$$

We have a commutative diagram

$$\begin{array}{ccc}
\text{Mod}^\text{Comm}(\mathcal{C}) & \to & \mathcal{D} \\
\downarrow & & \downarrow \\
\text{CAlg}(\mathcal{C}) & \to & \mathcal{D}' \\
\end{array}$$

where the horizontal maps on the left are given by composition with the retraction $r$ (since these are sections of the trivial Kan fibrations above, they are categorical equivalences) and the horizontal maps on the right are given by composition with the inclusion $\Delta^{op} \times [1] \hookrightarrow \mathcal{J}$. Consequently, it will suffice to prove that the square on the right is a homotopy pullback diagram. Since the vertical maps in this square are categorical fibrations between $\infty$-categories, it will suffice to show that the map $\mathcal{D} \to \Delta\text{LMod}(\mathcal{C}) \times_{\text{CAlg}(\mathcal{C})} \mathcal{D}'$ is a trivial Kan fibration. Let $\mathcal{J}''$ denote the full subcategory of $\mathcal{J}$ spanned by the objects of $\mathcal{J}'$ and $\Delta^{op} \times [1]$. We observe that $\Delta\text{LMod}(\mathcal{C}) \times_{\text{CAlg}(\mathcal{C})} \mathcal{D}'$ can be identified with the full subcategory of $\mathcal{D}'' \subseteq \text{Fun}_{\text{Comm}}^\otimes(N(\mathcal{J}''), \mathcal{C}^\otimes)$ spanned by those functors $F$ which satisfy conditions (i'), (ii'), and the following additional condition:

(iii') The restriction of $F$ to $N(\Delta)^{op} \times 1^\Delta$ belongs to $\Delta\text{LMod}(\mathcal{C})$.

We wish to prove that $\mathcal{D} \to \mathcal{D}''$ is a trivial Kan fibration. In view of Proposition T.4.3.2.15, it will suffice to prove the following:

(a) Every functor $F_0 \in \mathcal{D}''$ admits a $p$-right Kan extension $F \in \text{Fun}_{\text{Comm}}^\otimes(N(\mathcal{J}), \mathcal{C}^\otimes)$.

(b) Let $F \in \text{Fun}_{\text{Comm}}^\otimes(N(\mathcal{J}), \mathcal{C}^\otimes)$ be a functor such that $F_0 = F|N(\mathcal{J}'') \in \mathcal{D}''$. Then $F \in \mathcal{D}$ if and only if $F$ is a $p$-right Kan extension of $F_0$.

We first prove (a). Let $F_0 \in \mathcal{D}''$, and consider an object $\alpha : \langle 1 \rangle \to \langle n \rangle$ of $\mathcal{J}$ which does not belong to $\mathcal{J}'$, and let $i = \alpha(1) \in \langle n \rangle^\circ$. Let $\mathcal{J} = \mathcal{J}' \times_2 \mathcal{J}_{\alpha/}$. We wish to prove that the diagram $N(\mathcal{J}) \to \mathcal{C}^\otimes$ determined by $F_0$ can be extended to a $p$-limit diagram covering the map

$$N(\mathcal{J})^\circ \to N(\mathcal{J}_{\alpha/})^\circ \to N(\mathcal{J}) \to N(\mathcal{F}\text{in}_*).$$

Let $\mathcal{J}_0$ denote the full subcategory of $\mathcal{J}$ spanned by the objects of $\mathcal{J}' \times_2 \mathcal{J}_{\alpha/}$ together with those maps $\alpha \to ([n], 0)$ in $\mathcal{J}$ for which the underlying map $u : \langle n \rangle \to \psi([m] \times [0])$ satisfies the following condition: if $u(j) = u(i)$ for $j \in \langle n \rangle^\circ$, then $i = j$. It is not difficult to see that the inclusion $\mathcal{J}_0 \subseteq \mathcal{J}$ admits a right adjoint, so that $N(\mathcal{J}_0) \subseteq N(\mathcal{J})$ is right cofinal. Consequently, it will suffice to show that the induced map $G : N(\mathcal{J}_0) \to \mathcal{C}^\otimes$ can be extended to a $p$-limit diagram (compatible with the underlying map $N(\mathcal{J}_0)^\circ \to N(\mathcal{F}\text{in}_*)$).
4.5. MODULES OVER COMMUTATIVE ALGEBRAS

Let \( \mathcal{J}_1 \) denote the full subcategory of \( \mathcal{J}_0 \) spanned by the objects of \( \mathcal{J}' \times \mathcal{J}_0 \), together with the morphism \( s: \alpha \to ([0], 0) \) in \( \mathcal{J} \) given by the map \( \rho^i: (n) \to \psi([0] \ast [0]) \simeq (1) \). We claim that \( G \) is a \( p \)-right Kan extension of \( G|\mathcal{N}(\mathcal{J}_1) \). To prove this, consider an arbitrary object \( J \in \mathcal{J}_0 \) which does not belong to \( \mathcal{J}_1 \), which we identify with a map \( t: \alpha \to ([m], 0) \) in \( \mathfrak{I} \). We have a commutative diagram

\[
\begin{array}{c}
\xymatrix{ (t: \alpha \to ([m], 0)) \ar[r] & (s: \alpha \to ([0], 0)) \\
(t': \alpha \to ([m], 1)) \ar[r] & (s': \alpha \to ([0], 1)) }
\end{array}
\]

in \( \mathcal{J}_0 \), which we can identify with a diagram \( s \to s' \leftarrow t' \) in \( (\mathcal{J}_0)_J \times \mathcal{J}_0 \mathcal{J}_1 \). Using Theorem T.4.1.3.1, we deduce that this diagram determines a left cofinal map \( \Lambda_G^0 \to \mathcal{N}(\mathcal{J}_0)_J \times \mathcal{J}_0 \mathcal{J}_1 \). Consequently, to prove that \( G \) is a \( p \)-right Kan extension of \( G|\mathcal{N}(\mathcal{J}_1) \), it suffices to verify that the diagram

\[
\begin{array}{c}
\xymatrix{ F_0([m], 0) \ar[r] & F_0([0], 0) \\
F_0([m], 1) \ar[r] & F_0([1], 1) }
\end{array}
\]

is a \( p \)-limit diagram, which follows from \((iii')\). Using Lemma T.4.3.2.7, we are are reduced to proving that \( G_1 = G|\mathcal{N}(\mathcal{J}_1) \) can be extended to a \( p \)-limit diagram lifting the evident map \( \mathcal{N}(\mathcal{J}_1)^\circ \to \mathcal{N}(\mathfrak{I}) \).

Let \( \beta: (n) \to (n - 1) \) be an inert morphism such that \( \beta(i) = \ast \), and let \( \alpha': (1) \to (n - 1) \) be given by the composition \( \beta \circ \alpha \). Let \( \mathcal{J}_2 \) denote the full subcategory of \( \mathcal{J}_1 \) spanned by the map \( s: \alpha \to ([0], 0) \), the induced map \( s': \alpha \to ([0], 1) \), and the natural transformation \( \alpha \to \alpha' \) induced by \( \beta \). Using Theorem T.4.1.3.1, we deduce that the inclusion \( \mathcal{N}(\mathcal{J}_2) \subseteq \mathcal{N}(\mathcal{J}_1) \) is right cofinal. Consequently, we are reduced to proving that \( G_2 = G|\mathcal{N}(\mathcal{J}_2) \) can be extended to a \( p \)-limit diagram lifting the evident map \( \mathcal{N}(\mathcal{J}_2)^\circ \to \mathcal{N}(\mathfrak{I}) \). In other words, we must find a \( p \)-limit diagram

\[
\begin{array}{c}
\xymatrix{ F(\alpha) \ar[r] & F_0([0], 0) \\
F_0(\alpha') \ar[r] & F_0([1], 1) }
\end{array}
\]

covering the diagram

\[
\begin{array}{c}
\xymatrix{ (n) \ar[r]^{\rho'} & (1) \\
(\beta) \ar[d] & \\
(n - 1) \ar[r]^{(0)} & (0) }
\end{array}
\]

in \( \mathfrak{I} \). The existence of such a diagram follows immediately from our assumption that \( p: \mathcal{C} \to \mathcal{N}(\mathfrak{I}) \) is an \( \infty \)-operad (see Proposition 2.3.2.5). This completes the proof of \((a)\). Moreover, the proof also gives the following analogue of \((b)\):

\((b')\) Let \( F \in \text{FunComm}^\circ(|\mathcal{J}|, \mathcal{C}^\circ) \) be a functor such that \( F_0 = F|\mathcal{N}(\mathcal{J})' \) \( \subseteq \mathcal{D}'' \). Then \( F \) is a \( p \)-right Kan extension of \( F_0 \) if and only if it satisfies the following condition:

\((*)\) For every object \( \alpha: (1) \to (n) \) of \( \mathcal{J} \) which does not belong to \( \mathcal{J}' \), the induced diagram

\[
\begin{array}{c}
\xymatrix{ F(\alpha) \ar[r]^u & F_0([0], 0) \\
& F_0(\alpha') \ar[l]_v & F_0([1], 1) }
\end{array}
\]

is a p-limit diagram.

We observe that (⋆) can be reformulated as follows:

(⋆) For every object \( α : \{1\} \to \langle n \rangle \) of \( J \) which does not belong to \( J'' \), the induced morphisms \( u : F(α) \to F_0([0], 0) \) and \( v : F(α') \to F_0(α') \) are inert.

To complete the proof, it will suffice to show that if \( F \in \text{Fun}_{\text{Comm}^\otimes}(N(\mathcal{J}), \mathcal{E}^\otimes) \) satisfies (i′), (ii′), and (iii′), then \( F \) satisfies condition (⋆) if and only if it satisfies conditions (i) and (ii). We first prove the “if” direction. The assertion that \( v \) is inert follows immediately from (i). To see that \( u \) is inert, choose a map \( u_0 : α \to ([n - 1], 0) \) in \( J \) corresponding to an isomorphism \( \langle n \rangle \simeq ψ([n - 1] \ast [0]) \), so that \( u \) factors as a composition

\[
F(α) \xrightarrow{F(u_0)} F([n - 1], 0) \xrightarrow{F(u_1)} F([0], 0).
\]

The map \( F(u_0) \) is inert by virtue of (ii), and the map \( F(u_1) \) is inert by virtue of (iii′).

We now prove the “only if” direction. Suppose that \( F \) satisfies (i′), (ii′), (iii′), and (⋆). We first claim that \( F \) satisfies (i). Let \( f : α \to β \) be a morphism in \( J_0 \) whose image in \( \mathcal{T}_n \), is inert; we wish to prove that \( F(f) \) is an inert morphism in \( \mathcal{E}^\otimes \). If \( α \in J' \), then this follows from assumption (i′). If \( β \in J' \) and \( α \notin J' \), then we can factor \( f \) as a composition

\[
α \xrightarrow{f'} α' \xrightarrow{f''} β
\]

where \( α' \in J' \) is defined as above. Then \( F(f'') \) is inert by virtue of (i′), while \( F(f') \) is inert by (⋆), so that \( F(f) \) is inert as desired. Finally, suppose that \( β : \{1\} \to \langle m \rangle \) does not belong to \( J' \), so that \( β(1) = i \in \langle m \rangle \).

To prove that \( F(f) \) is inert, it will suffice to show that for each \( j \in \langle m \rangle \), there exists an inert morphism \( γ_j : F(β) \to C_j \) in \( \mathcal{E}^\otimes \) covering \( ρ^j : \langle m \rangle \to \{1\} \) such that \( γ_j \circ F(f) \) is inert. If \( j = i \), we can take \( γ_j = F(g) \), where \( β_i = ρ^i \circ β \) and \( g : β \to β_i \) is the induced map; then \( β_j = J' \) so that \( F(g) \) and \( F(g \circ f) \) are both inert by the arguments presented above. If \( i = j \), we take \( γ_j = F(g) \) where \( g \) is the map \( β \to ([0], 0) \) in \( J \) determined by \( ρ^i \). Then \( F(g) \) and \( F(g \circ f) \) are both inert by virtue of (⋆). (This completes the proof of (i).

We now prove (ii). Let \((n, i) \in N(\Delta)^{op} \times \Delta^1 \), let \( α = Ψ([n], i) \in J_0 \), and let \( f : α \to ([n], i) \) be the canonical morphism in \( J \). We wish to prove that \( F(f) \) is an equivalence in \( \mathcal{E}^\otimes \). If \( i = 1 \), this follows from (ii′). Assume therefore that \( i = 0 \). Observe that \( α \) can be identified with the morphism \( \{1\} \to \langle n + 1 \rangle \) carrying \( 1 \in \{1\} \) to \( n + 1 \in \langle n + 1 \rangle \). To prove that \( F(f) \) is an equivalence, it will suffice to show that for each \( j \in \langle n + 1 \rangle \), there exists an inert morphism \( γ_j : F([n], 0) \to C_j \) in \( \mathcal{E}^\otimes \) covering \( ρ^j : \langle n + 1 \rangle \to \{1\} \) such that \( γ_j \circ F(f) \) is also inert. If \( j \neq n + 1 \), we take \( γ_j = F(g) \), where \( g : ([n], 0) \to ([1], 1) \) is a morphism in \( Δ^\otimes \times \{1\} \) covering the map \( ρ^i \). Then \( γ_j \) is inert by virtue of (ii′), while \( γ_j \circ F(f) \simeq F(g \circ f) \) can be written as a composition

\[
F(α) \xrightarrow{F(h')} F(α') \xrightarrow{F(h'')} F(ρ([1], 1)) \xrightarrow{F(h''')} F([1], 1).
\]

Assumption (⋆) guarantees that \( F(h') \) is inert, assumption (i′) guarantees that \( F(h'') \) is inert, and assumption (ii′) guarantees that \( F(h''') \) is inert. It follows that \( F(h''' \circ h''' \circ h') \simeq F(g \circ f) \) is inert as desired. In the case \( j = n + 1 \), we instead take \( γ_j = F(g) \) where \( g : ([n], 0) \to ([0], 0) \) is the morphism in \( J \) determined by the map \( [0] \to [n] \) in \( Δ \) carrying \( 0 \in [0] \) to \( n \in [n] \). Then \( γ_j = F(g) \) is inert by virtue of (iii′), while \( γ_j \circ F(f) \simeq F(g \circ f) \) is inert by virtue of (⋆).

\[

\]

### 4.5.2 Tensor Products over Commutative Algebras

Let \( R \) be a commutative ring. Then the category of \( R \)-modules is endowed with a symmetric monoidal structure, whose tensor product operation is given by \( (M, N) \to M \otimes_R N \). Our goal in this section is to establish a generalization of this statement, where we replace the category of abelian groups by an arbitrary symmetric monoidal \( ∞ \)-category \( C \). Let \( A \) be a commutative algebra object of \( C \), and let us abuse notation by identifying \( A \) with the underlying associative algebra object of \( C \). We have seen that the \( ∞ \)-category \( \text{Mod}^A^\text{Ass}(C) \) can be identified with the \( ∞ \)-category of \( A-A \)-bimodules (Theorem 4.4.1.28). Moreover, under some mild hypotheses, the relative tensor product functor \( ⊗_A \) endows \( \text{Mod}^A^\text{Ass}(C) \) with the structure of a monoidal \( ∞ \)-category (Proposition 4.4.3.12). Our main result can be stated as follows:
Theorem 4.5.2.1. Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category. Assume that $\mathcal{C}$ admits geometric realizations of simplicial objects, and that the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves geometric realizations of simplicial objects separately in each variable. Let $A$ be a commutative algebra object of $\mathcal{C}$. Then:

1. The $\infty$-operad $\Mod_A(\mathcal{C})^\otimes$ is a symmetric monoidal $\infty$-category.
2. The forgetful functor $\psi : \Mod_A(\mathcal{C})^\otimes \times_{N(\text{Fin}_\ast)} \text{Ass}^\otimes \to \Mod_A^{\text{Ass}}(\mathcal{C})^\otimes$ of Remark 4.5.1.2 is monoidal. In particular, we can identify the tensor product operation on $\Mod_A(\mathcal{C})$ with the composition

$$\Mod_A(\mathcal{C}) \times \Mod_A(\mathcal{C}) \to A\text{BMod}_A(\mathcal{C}) \times A\text{BMod}_A(\mathcal{C}) \xrightarrow{\otimes} A\text{BMod}_A(\mathcal{C}) \to \text{LMod}_A(\mathcal{C}) \simeq \Mod_A(\mathcal{C})$$

(see Proposition 4.4.3.12).

The proof of Theorem 4.5.2.1 will make use of the following criterion for detecting symmetric monoidal structures.

Proposition 4.5.2.2. Let $q : \mathcal{C}^\otimes \to N(\text{Fin}_\ast)$ be an $\infty$-operad. Then $q$ is a coCartesian fibration if and only if the following conditions are satisfied:

1. The fibration $q$ has units (in the sense of Definition 3.2.1.1).
2. Let $\alpha : \langle 2 \rangle \to \langle 1 \rangle$ be an active morphism in $N(\text{Fin}_\ast)$, and let $X \in \mathcal{C}^\otimes_{\langle 2 \rangle}$. Then there exists a map $\overline{\alpha} : X \to X'$ with $q(\overline{\alpha}) = q(q)$, which determines an operadic $q$-colimit diagram $\Delta^1 \to \mathcal{C}^\otimes$.

Proof. If $q$ is a coCartesian fibration, then conditions (1) and (2) follow immediately from Proposition 3.1.1.13. Conversely, suppose that (1) and (2) are satisfied; we wish to prove that $q$ is a coCartesian fibration. In view of Proposition 3.1.1.13, it will suffice to prove that the following stronger version of (2) is satisfied:

$$\langle 2 \rangle \to \langle 1 \rangle$$

(2') Let $\alpha : \langle n \rangle \to \langle 1 \rangle$ be an active morphism in $N(\text{Fin}_\ast)$, and let $X \in \mathcal{C}^\otimes_{\langle n \rangle}$. Then there a map $\overline{\alpha} : X \to X'$ lifting $\alpha$ which is given by an operadic $q$-colimit diagram.

We verify (2') using induction on $n$. If $n = 0$, the desired result follows from (1). If $n = 1$, then $\alpha$ is the identity and we can choose $\overline{\alpha}$ to be a degenerate edge. Assume that $n \geq 2$. Choose any partition of this set into nonempty disjoint subsets $\langle n \rangle^\circ_-$ and $\langle n \rangle^\circ_+$. This decomposition determines a factorization of $\alpha$ as a composition

$$\langle n \rangle \xrightarrow{\langle \alpha \rangle} \langle 2 \rangle \xrightarrow{\langle \gamma \rangle} \langle 1 \rangle.$$

Let $n_-$ and $n_+$ be the cardinalities of $\langle n \rangle^\circ_-$ and $\langle n \rangle^\circ_+$, respectively, so that our decomposition induces inert morphisms $\langle n \rangle \to \langle n_+ \rangle$ and $\langle n \rangle \to \langle n_- \rangle$. Since $q$ is a fibration of $\infty$-operads, we can lift these maps to inert morphisms $X \to X_-$ and $X \to X_+$ in $\mathcal{C}^\otimes$. Using the inductive hypothesis, we choose morphisms $X_\ast \to X'_\ast$ and $X_+ \to X'_+$ lying over the maps $\langle n_- \rangle \to \langle 1 \rangle \leftarrow \langle n_+ \rangle$. Using (2), we can choose a morphism $\alpha'' : X'_- \otimes X'_+ \to X'_- \otimes X'_+$ which is classified by an operadic $q$-colimit diagram. To complete the proof, it will suffice to show that $\overline{\alpha''} \circ \overline{\alpha'}$ is classified by an operadic $q$-colimit diagram. Choose an object $Y \in \mathcal{C}^\otimes$; we must show that the composite map

$$X \otimes Y \simeq X_- \otimes X_+ \oplus Y \xrightarrow{\beta} X'_- \otimes X'_+ \oplus Y \xrightarrow{\gamma} X'_- \oplus Y$$

is classified by a weak operadic $q$-colimit diagram. To prove this, it suffices to show that $\gamma \circ \beta$ is $q$-coCartesian. In view of Proposition T.2.4.1.7, it suffices to show that $\gamma$ and $\beta$ are $q$-coCartesian, which follows from Proposition 3.1.1.10.

Proof of Theorem 4.5.2.1. We will prove (1) using Proposition 4.5.2.2. Note that $\Mod_A(\mathcal{C})^\otimes \to N(\text{Fin}_\ast)$ automatically has units (Example 3.4.4.5). It will therefore suffice to prove the following:
(⋆) For every object \( X \in \text{Mod}_A(\mathcal{C})^{\otimes}_{(2)} \), there exists a morphism \( f : X \to Y \) in \( \text{Mod}_A(\mathcal{C})^{\otimes} \) covering the active morphism \( (2) \to (1) \) in \( \text{Fin}_\star \) and classified by an operadic \( p \)-colimit diagram, where \( p : \text{Mod}_A(\mathcal{C})^{\otimes} \to N(\text{Fin}_\star) \) denotes the projection.

Let \( \mathcal{D} \) denote the subcategory of \( N(\text{Fin}_\star)_{(2)} / \) whose objects are injective maps \( (2) \to (n) \) and whose morphisms are diagrams

\[
\begin{array}{ccc}
(2) & \xrightarrow{u} & (n) \\
\downarrow & & \downarrow \\
(\langle m \rangle) & & \langle n \rangle
\end{array}
\]

where \( u \) is active, so that \( \mathcal{D}^{\otimes} \) maps to \( N(\text{Fin}_\star) \) by a map carrying the cone point of \( \mathcal{D}^{\otimes} \) to \( (1) \). The category \( \mathcal{D} \) has an evident forgetful functor \( \mathcal{D} \to \mathcal{K}_{\text{Comm}} \times \text{Comm}^{\otimes}_{(2)} \), so that \( X \) determines a functor \( F_0 \in \text{Fun}_{N(\text{Fin}_\star)}(\mathcal{D}, \mathcal{C}^{\otimes}) \). In view of Theorem 3.4.4.3, to prove (⋆) it will suffice to show that \( F_0 \) can be extended to an operadic \( p \)-colimit diagram \( F \in \text{Fun}_{N(\text{Fin}_\star)}(\mathcal{D}^{\otimes}, \mathcal{C}^{\otimes}) \).

In view of our assumption on \( \mathcal{C}^{\otimes} \) and Proposition 3.1.1.20, the existence of \( F \) will follow provided that we can exhibit a left cofinal map \( \phi : N(\Delta)^{\otimes} \to \mathcal{D} \). We define \( \phi \) by a variation of Construction 4.1.2.5. Let \( \mathcal{J} \) denote the category whose objects are finite sets \( S \) containing a pair of distinct elements \( x, y \in S \), so we have a canonical equivalence \( \mathcal{D} \simeq N(\mathcal{J}) \). We will obtain \( \phi \) as the nerve of a functor \( \phi_0 : \Delta^{\otimes} \to \mathcal{J} \), where \( \phi_0([n]) \) is the set of all downward-closed subsets of \( [n] \) (with distinguished points given by \( 0, [n] \subseteq [n] \)). To prove that \( \phi \) is left cofinal, it will suffice to show that for each \( S = (S, x, y) \in \mathcal{J} \), the category \( \mathcal{J} = \Delta^{\otimes} \times \mathcal{J} \) has weakly contractible nerve. Writing \( S = S_0 \coprod \{x, y\} \), we can identify \( \mathcal{J}^{\otimes} \) with the category of simplices of the simplicial set \( (\Delta^1)^{S_0} \). Since \( (\Delta^1)^{S_0} \) is weakly contractible, it follows that \( N(\mathcal{J}) \) is weakly contractible. This proves (1).

We now prove (2). Since the forgetful functor \( \psi \) clearly preserves units (Corollary 3.4.4.4), it will suffice to verify the following:

\((\ast')\) Let \( X \in \text{Mod}_A(\mathcal{C})^{\otimes}_{(2)} \), let \( \alpha : (2) \to (1) \) be an active morphism in \( \text{Ass}^{\otimes} \), let \( \alpha_0 \) be its image in \( \text{Comm}^{\otimes} \), and let \( \bar{\alpha}_0 : X \to Y \) be a \( q \)-coCartesian morphism in \( \text{Mod}_A(\mathcal{C})^{\otimes} \) lifting \( \alpha_0 \). Then the induced morphism \( \bar{\alpha} \) in \( \text{Mod}_A^{\text{Ass}}(\mathcal{C})^{\otimes} \) is \( q' \)-coCartesian (where \( q' : \text{Mod}_A^{\text{Ass}}(\mathcal{C})^{\otimes} \to \text{Ass}^{\otimes} \) denotes the projection).

Using Proposition 3.1.1.15, we deduce that \( \bar{\alpha}_0 \) is classified by an operadic \( q \)-colimit diagram \( \Delta^1 \to \text{Mod}_A(\mathcal{C})^{\otimes} \). Applying Theorem 3.4.4.3, we deduce that the underlying diagram \( \mathcal{D}^{\otimes} \to \mathcal{C}^{\otimes} \) is an operadic \( p \)-colimit diagram. By the cofinality argument above, we conclude that \( \bar{\alpha}_0 \) induces an operadic \( p \)-colimit diagram \( N(\Delta^{\otimes}q') \to \mathcal{C}^{\otimes} \). The desired result now follows from the description of the tensor product on \( \text{Mod}_A^{\text{Ass}}(\mathcal{C}) \) supplied by Proposition 4.4.3.12 (together with Theorem 4.4.2.8).

### 4.5.3 Change of Algebra

Let \( f : A \to B \) be a commutative ring. Via the map \( f \), every \( B \)-module can be regarded as an \( A \)-module. This construction determines a forgetful functor from the (ordinary) category \( \text{Mod}_B \) of \( B \)-modules to the (ordinary) category \( \text{Mod}_A \) of \( A \)-modules. This forgetful functor has a left adjoint, given by the construction \( M \mapsto B \otimes_A M \). This left adjoint is symmetric monoidal: that is, for every pair of \( A \)-modules \( M \) and \( N \), there is a canonical isomorphism

\[
B \otimes_A (M \otimes_A N) \simeq (B \otimes_A M) \otimes_B (B \otimes_A N).
\]

Our goal in this section is to prove an analogous result, where the commutative rings \( A \) and \( B \) are replaced by commutative algebra objects in an arbitrary symmetric monoidal \( \infty \)-category. Our main result can be stated as follows:

**Theorem 4.5.3.1.** Let \( \mathcal{C}^{\otimes} \) be a symmetric monoidal \( \infty \)-category. Assume that \( \mathcal{C} \) admits geometric realizations of simplicial objects, and that the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations separately in each variable. Then the map \( p : \text{Mod}(\mathcal{C})^{\otimes} \to \text{CAlg}(\mathcal{C}) \times N(\text{Fin}_\star) \) is a coCartesian fibration.
Remark 4.5.3.2. Let $\mathcal{C}^\otimes$ be as in Theorem 4.5.3.1. The coCartesian fibration $\text{Mod}(\mathcal{C})^\otimes \to \text{CAlg}(\mathcal{C}) \times N(\text{Fin}_*)$ is classified by functor $\text{CAlg}(\mathcal{C}) \times N(\text{Fin}_*) \to \text{Cat}_\infty$, which we can interpret as a functor $\text{CAlg}(\mathcal{C}) \to \text{Mon}_{\text{Comm}}(\text{Cat}_\infty)$. In particular, every morphism $f : A \to B$ of commutative algebra objects of $\mathcal{C}$ determines a morphism in $\text{Mon}_{\text{Comm}}(\text{Cat}_\infty) \subseteq \text{Fun}(N(\text{Fin}_*), \text{Cat}_\infty)$, which classifies a symmetric monoidal functor $\text{Mod}_A(\mathcal{C})^\otimes \to \text{Mod}_B(\mathcal{C})^\otimes$.

Remark 4.5.3.3. Theorem 4.5.3.1 singles out a special property enjoyed by the commutative $\infty$-operad. If $f : A \to B$ is a map of associative algebra objects of $\mathcal{C}$, then the forgetful functor

$$B \text{BMod}_B(\mathcal{C}) \simeq \text{Mod}_B^{\text{Ass}}(\mathcal{C}) \to \text{Mod}_A^{\text{Ass}}(\mathcal{C}) \simeq A \text{BMod}_A(\mathcal{C})$$

also has a left adjoint, given by the construction $M \mapsto B \otimes_A M \otimes_A B$. However, this left adjoint is not a monoidal functor: if $M$ and $N$ are objects of $A \text{BMod}_A(\mathcal{C})$, then there is an induced map

$$B \otimes_A M \otimes_A N \otimes_A B \to B \otimes_A M \otimes_A B \otimes_A N \otimes_A N \simeq (B \otimes_A M \otimes_A B) \otimes_B (B \otimes_A N \otimes_A B)$$

which is in general not an equivalence.

The proof of Theorem 4.5.3.1 will require some preliminaries.

Lemma 4.5.3.4. Let $S$ be an $\infty$-category and let $p : \mathcal{C}^\otimes \to S \times N(\text{Fin}_*)$ be an $S$-family of $\infty$-operads. Assume that:

(a) The composite map $p' : \mathcal{C}^\otimes \to S$ is a Cartesian fibration; moreover, the image in $N(\text{Fin}_*)$ of any $p'$-Cartesian morphism of $\mathcal{C}^\otimes$ is an equivalence.

(b) For each $s \in S$, the induced map $p_s : \mathcal{C}_s^\otimes \to N(\text{Fin}_*)$ is a coCartesian fibration.

(c) The underlying map $p_0 : \mathcal{C} \to S$ is a coCartesian fibration.

Then:

(1) The map $p$ is a locally coCartesian fibration.

(2) A morphism $f$ in $\mathcal{C}^\otimes$ is locally $p$-coCartesian if and only if it factors as a composition $f'' \circ f'$, where $f'$ is a $p_s$-coCartesian morphism in $\mathcal{C}_s^\otimes$ for some $s \in S$ (here $p_s : \mathcal{C}_s^\otimes \to N(\text{Fin}_*)$ denotes the restriction of $p$) and $f'' : Y \to Z$ is a morphism in $\mathcal{C}_{(n)}$ with the following property: for $1 \leq i \leq n$, there exists a commutative diagram

$$
\begin{array}{ccc}
Y & \xrightarrow{f'} & Z \\
\downarrow & & \downarrow \\
y_i & \xrightarrow{f''} & z_i \\
\end{array}
$$

where the vertical maps are inert morphisms of $\mathcal{C}^\otimes$ lying over $\rho^i : (n) \to (1)$ and the map $f''_i$ is a locally $p_0$-coCartesian morphism in $\mathcal{C}$.

Proof. Let $f \simeq f' \circ f''$ be as in (2), and let $y, z \in S$ denote the images of $Y, Z \in \mathcal{C}^\otimes$. Using the equivalences

$$\mathcal{C}^\otimes \times S \times N(\text{Fin}_*)(y, (n)) \simeq \mathcal{C}^n_y \quad \mathcal{C}^\otimes \times S \times N(\text{Fin}_*)(z, (n)) \simeq \mathcal{C}^n_z,$$

we deduce that if $f''$ satisfies the stated condition, then $f''$ is locally $p$-coCartesian. If $f'$ is a $p_s$-coCartesian morphism in $\mathcal{C}_s^\otimes$, then condition (a) and Corollary T.4.3.1.15 guarantee that $f'$ is $p$-coCartesian. Replacing $p$ by the induced fibration $\mathcal{C}^\otimes \times S \times N(\text{Fin}_*) \Delta^2 \to \Delta^2$ and applying Proposition T.2.4.1.7, we deduce that $f$ is locally $p$-coCartesian. This proves the “if” direction of (2).
To prove (1), consider an object $X \in \mathcal{C}^\otimes$ lying over $(s, \langle n \rangle) \in S \times N(\mathrm{Fin}_*)$, and let $f_0 : (s, \langle n \rangle) \rightarrow (s', \langle n' \rangle)$ be a morphism in $S \times N(\mathrm{Fin}_*)$. Then $f_0$ factors canonically as a composition

$$(s, \langle n \rangle) \xrightarrow{f_0} (s', \langle n' \rangle).$$

Using assumption (b), we can lift $f_0$ to a $p_\alpha$-coCartesian morphism $f' : X \rightarrow Y$ in $\mathcal{C}^\otimes$, and using (c) we can lift $f_0$ to a morphism $f'' : Y \rightarrow Z$ in $\mathcal{C}^\otimes_{(n)}$ satisfying the condition given in (2). It follows from the above argument that $f = f'' \circ f'$ is a locally $p$-coCartesian morphism of $\mathcal{C}^\otimes$ lifting $f_0$. This proves (1).

The “only if” direction of (2) now follows from the above arguments together with the uniqueness properties of locally $p$-coCartesian morphisms.

For the statement of the next lemma, we need to introduce a bit of terminology. Let $p : \mathcal{C}^\otimes \rightarrow S \times N(\mathrm{Fin}_*)$ be as in Lemma 4.5.3.4, and let $f : X \rightarrow Y$ be a locally $p$-coCartesian morphism in $\mathcal{C}^\otimes_{(n)}$ for some $n \geq 0$. If $\alpha : \langle n \rangle \rightarrow \langle n' \rangle$ is a morphism in $\mathrm{Fin}_*$, we will say that $f$ is $\alpha$-good if the following condition is satisfied:

\begin{itemize}
  \item[(*)] Let $x, y \in S$ denote the images of $X, Y \in \mathcal{C}^\otimes$, and choose morphisms $\pi_x : X \rightarrow X'$ in $\mathcal{C}^\otimes_x$ and $\pi_y : Y \rightarrow Y'$ in $\mathcal{C}^\otimes_y$ which are $p_x$ and $p_y$-coCartesian lifts of $\alpha$, respectively, so that we have a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{\pi_x} & & \downarrow{\pi_y} \\
X' & \xrightarrow{f'} & Y'.
\end{array}
\]

Then $f'$ is locally $p$-coCartesian.
\end{itemize}

**Lemma 4.5.3.5.** Let $p : \mathcal{C}^\otimes \rightarrow S \times N(\mathrm{Fin}_*)$ be as in Lemma 4.5.3.4. The following conditions are equivalent:

1. The map $p$ is a coCartesian fibration.

2. For every morphism $f : X \rightarrow Y$ in $\mathcal{C}^\otimes_{(n)}$ and every morphism $\alpha : \langle n \rangle \rightarrow \langle n' \rangle$, the morphism $f$ is $\alpha$-good.

3. For every morphism $f : X \rightarrow Y$ in $\mathcal{C}^\otimes_{(n)}$ where $n \in \{0, 2\}$ and every active morphism $\alpha : \langle n \rangle \rightarrow \langle 1 \rangle$, the morphism $f$ is $\alpha$-good.

**Proof.** The implication (1) $\Rightarrow$ (2) follows from Proposition T.2.4.1.7 and the implication (2) $\Rightarrow$ (3) is obvious. We next prove that (2) $\Rightarrow$ (1). Since $p$ is a locally coCartesian fibration (Lemma 4.5.3.4), it will suffice to show that if $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ are locally $p$-coCartesian morphisms in $\mathcal{C}^\otimes$, then $g \circ f$ is locally $p$-coCartesian (Proposition T.2.4.2.8). Using Lemma 4.5.3.4, we can assume that $f = f'' \circ f'$, where $f'$ is $p$-coCartesian and $f''$ is a locally $p$-coCartesian morphism in $\mathcal{C}^\otimes_{(n)}$ for some $n \geq 0$. To prove that $g \circ f \simeq (g \circ f'') \circ f'$ is locally $p$-coCartesian, it will suffice to show that $g \circ f''$ is locally $p$-coCartesian. We may therefore replace $f$ by $f''$ and thereby assume that $f$ has degenerate image in $N(\mathrm{Fin}_*)$. Applying Lemma 4.5.3.4 again, we can write $g = g'' \circ g'$ where $g' : Y \rightarrow Y'$ is a $p$-coCartesian morphism in $\mathcal{C}^\otimes \otimes_{(n)}$ covering some map $\alpha : \langle n \rangle \rightarrow \langle n' \rangle$, and $g''$ is a locally $p$-coCartesian morphism in $\mathcal{C}^\otimes_{(n'')}$. Let $x$ denote the image of $X$ in $S$, and let $k : X \rightarrow X'$ be a $p$-coCartesian morphism in $\mathcal{C}^\otimes_x$ lying over $\alpha$. We have a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{k} & Y \\
\downarrow{g'} & & \downarrow{g''} \\
X' & \xrightarrow{h} & Y'.
\end{array}
\]

Since $f$ is $\alpha$-good (by virtue of assumption (2)), we deduce that $h$ is locally $p$-coCartesian. To prove that $g \circ f \simeq (g'' \circ h) \circ k$ is locally $p$-coCartesian, it will suffice (by virtue of Lemma 4.5.3.4) to show that $g'' \circ h$ is locally $p$-coCartesian. We claim more generally that the collection of locally $p$-coCartesian edges in $\mathcal{C}^\otimes_{(n)}$
is closed under composition. This follows from the observation that $\mathbb{C}^\otimes_{(n)} \to S$ is a coCartesian fibration (being equivalent to a fiber power of the coCartesian fibration $p_0 : \mathbb{C} \to S$). This completes the proof that (2) $\Rightarrow$ (3).

We now prove that (3) $\Rightarrow$ (2). Let us say that a morphism $\alpha : \langle n \rangle \to \langle m \rangle$ is perfect if every locally $p$-coCartesian morphism $f$ in $\mathbb{C}^\otimes_{(n)}$ is $\alpha$-good. Assumption (3) guarantees that the active morphisms $\langle 2 \rangle \to \langle 1 \rangle$ and $\langle 0 \rangle \to \langle 1 \rangle$ are perfect; we wish to prove that every morphism in $\mathcal{F}\text{in}_a$ is perfect. This follows immediately from the following three claims:

(i) If $\alpha : \langle n \rangle \to \langle m \rangle$ is perfect, then for each $k \geq 0$ the induced map $\langle n + k \rangle \to \langle m + k \rangle$ is perfect.

(ii) The unique (inert) morphism $\langle 1 \rangle \to \langle 0 \rangle$ is perfect.

(iii) The collection of perfect morphisms in $\mathcal{F}\text{in}_a$ is closed under composition.

Assertions (i) and (ii) are obvious. To prove (iii), suppose that we are given perfect morphisms $\alpha : \langle n \rangle \to \langle m \rangle$ and $\beta : \langle m \rangle \to \langle k \rangle$. Let $f : X \to Y$ be a locally $p$-coCartesian morphism in $\mathbb{C}^\otimes_{(n)}$, and form a commutative diagram

$$
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow & & \downarrow \\
X' & \xrightarrow{f'} & Y' \\
\downarrow & & \downarrow \\
X'' & \xrightarrow{f''} & Y''
\end{array}
$$

where the upper vertical maps are $p$-coCartesian lifts of $\alpha$ and the lower vertical maps are $p$-coCartesian lifts of $\beta$. Since $\alpha$ is perfect, the map $f'$ is locally $p$-coCartesian. Since $\beta$ is perfect, the map $f''$ is locally $p$-coCartesian, from which it follows that $f$ is $\beta \circ \alpha$-good as desired.

**Lemma 4.5.3.6.** Let $\mathbb{C}^\otimes$ be a monoidal $\infty$-category. Assume that $\mathbb{C}$ admits geometric realizations of simplicial objects and that the tensor product functor $\otimes : \mathbb{C} \times \mathbb{C} \to \mathbb{C}$ preserves geometric realizations separately in each variable. Then the forgetful functor $\theta : \text{LMod}(\mathbb{C}) \to \text{Alg}(\mathbb{C})$ is a coCartesian fibration.

**Proof.** Corollary 4.2.3.2 guarantees that $\theta$ is a Cartesian fibration. In view of Proposition T.5.2.25, it will suffice to show that for each morphism $f : A \to B$ in $\text{Alg}(\mathbb{C})$, the forgetful functor $\text{LMod}_B(\mathbb{C}) \to \text{LMod}_A(\mathbb{C})$ has a left adjoint. This follows from Proposition 4.6.2.17.

**Proof of Theorem 4.5.3.1.** We first show that $p$ is a locally coCartesian fibration by verifying the hypotheses of Lemma 4.5.3.4:

(a) The map $p' : \text{Mod}(\mathbb{C})^\otimes \to \text{CAlg}(\mathbb{C})$ is a Cartesian fibration by virtue of Corollary 3.4.3.4; moreover, a morphism $f$ in $\text{Mod}(\mathbb{C})^\otimes$ is $p'$-Cartesian if and only if its image in $\mathbb{C}^\otimes$ is an equivalence (which implies that its image in $N(\mathcal{F}\text{in}_a)$ is an equivalence).

(b) For each $A \in \text{CAlg}(\mathbb{C})$, the fiber $\text{Mod}_A(\mathbb{C})^\otimes$ is a symmetric monoidal $\infty$-category (Theorem 4.5.2.1).

(c) The map $p_0 : \text{Mod}(\mathbb{C}) \to \text{CAlg}(\mathbb{C})$ is a coCartesian fibration. This follows from Corollary 4.5.1.6, because the forgetful functor $\text{LMod}(\mathbb{C}) \to \text{Alg}(\mathbb{C})$ is a coCartesian fibration (Lemma 4.5.3.6).

To complete the proof, it will suffice to show that $p$ satisfies condition (3) of Lemma 4.5.3.5. Fix a map $f_0 : A \to B$ in $\text{CAlg}(\mathbb{C})$ and a locally $p$-coCartesian morphism $f : M_A \to M_B$ in $\text{Mod}(\mathbb{C})^\otimes_{(n)}$ covering $f$; we wish to prove that $f$ is $\alpha$-good, where $\alpha : \langle n \rangle \to \langle 1 \rangle$ is the unique active morphism (here $n = 0$ or $n = 2$). Let $\mathcal{D}^\otimes = \text{Mod}_A(\mathbb{C})^\otimes$. Theorem 4.5.2.1 implies that $\mathcal{D}^\otimes$ is a symmetric monoidal $\infty$-category, Corollaries 4.5.1.6 and 4.2.3.5 imply that $\mathcal{D}$ admits geometric realizations of simplicial objects, and Corollary 4.4.2.15 implies that the tensor product on $\mathcal{D}$ preserves geometric realizations separately in each variable. Corollary
3.4.1.8 implies that the forgetful functor \( \text{Mod}(\mathcal{D})^\circ \to \text{Mod}(\mathcal{E})^\circ \times \text{CAlg}(\mathcal{E}) \text{CAlg}(\mathcal{E})^A/ \) is an equivalence of \( \infty \)-categories. Replacing \( \mathcal{E}^\circ \) by \( \mathcal{D}^\circ \), we may assume without loss of generality that \( A \) is a unit algebra in \( \mathcal{E}^\circ \).

Suppose first that \( n = 0 \). Unwinding the definitions, we are required to show that if \( M_A \to M'_A \) and \( M_B \to M'_B \) are morphisms \( \text{Mod}(\mathcal{E})^\circ \) which exhibit \( M'_A \in \text{Mod}_A(\mathcal{E}) \) as a \( p_A \)-unit (see Definition 3.2.1.1; here \( p_A : \text{Mod}_A(\mathcal{E})^\circ \to N(\text{Fin}_A) \) denotes the restriction of \( p \) and \( M'_B \in \text{Mod}_B(\mathcal{E}) \) as a \( p_B \)-unit (where \( p_B \) is defined similarly), then the induced map \( f' : M'_A \to M'_B \) is locally \( p \)-coCartesian. Using Corollary 3.4.3.4, it suffices to show that \( \phi(f') \) is an equivalence, where \( \phi : \text{Mod}(\mathcal{E}) \to \mathcal{E} \) is the forgetful functor. Using Corollary 3.4.4.4 and Proposition 4.5.1.4, this translates into the following assertion: the map \( A \to B \) exhibits \( B \) as the free left \( B \)-module generated by \( A \). This follows from Corollary 4.2.4.8.

We now treat the case \( n = 2 \). Since \( A \) is a unit algebra, Proposition 3.4.2.1 allows us to identify \( M_A \) with a pair of objects \( P, Q \in \mathcal{E} \). We can identify \( M_B \) with a pair of objects \( P_B, Q_B \in \text{Mod}_B(\mathcal{E}) \). Let us abuse notation by identifying \( P_B \) and \( Q_B \) with their images in \( \text{Mod}^\text{Ass}(\mathcal{E}) \simeq B\text{Mod}^\text{Ass}(\mathcal{E}) \). Unwinding the definitions (and using Theorem 4.5.2.1), it suffices to show that the canonical map \( f' : P \otimes Q \to (P_B \otimes Q_B) \) exhibits the relative tensor product \( P_B \otimes_B Q_B \) as the free left \( B \)-module generated by \( P \otimes Q \). This follows from the calculation

\[
B \otimes (P \otimes Q) \simeq (B \otimes P) \otimes Q \simeq (B \otimes P) \otimes_1 Q \simeq (B \otimes P) \otimes_B (B \otimes Q).
\]

(see Remark 4.4.2.9).

\[\square\]

### 4.5.4 Rectification of Commutative Algebras

Let \( \mathbf{A} \) be a symmetric monoidal model category (Definition 4.1.3.8). In §4.1.3, we saw that the underlying \( \infty \)-category \( N(\mathbf{A})_c[W^{-1}] \) of \( \mathbf{A} \) inherits the structure of a symmetric monoidal \( \infty \)-category, for which the natural map \( N(\mathbf{A})_c \to N(\mathbf{A})_c[W^{-1}] \) can be promoted to a symmetric monoidal functor. In particular, every associative algebra object of \( \mathbf{A} \) (which is cofibrant as an object of \( \mathbf{A} \)) determines an associative algebra object of the underlying \( \infty \)-category \( N(\mathbf{A})_c[\mathbf{W}^{-1}] \). Under some mild hypotheses, Proposition 4.1.4.3 guarantees that the category of associative algebra objects \( \text{Alg}(\mathbf{A}) \) is equipped with a model structure, and Theorem 4.1.4.4 implies that the underlying \( \infty \)-category of \( \text{Alg}(\mathbf{A}) \) is equivalent to \( \text{Alg}(N(\mathbf{A})_c[\mathbf{W}^{-1}]) \). Our goal in this section is to prove analogous results concerning the relationship between commutative algebra objects of \( \mathbf{A} \) and \( N(\mathbf{A})_c[\mathbf{W}^{-1}] \). These results will require some rather strong assumptions relating the model structure on \( \mathbf{A} \) and the symmetric monoidal structure on \( \mathbf{A} \), which we now formulate.

**Notation 4.5.4.1.** Let \( \mathbf{A} \) be a symmetric monoidal category which admits colimits. Given a pair of morphisms \( f : A \to A', g : B \to B' \), we let \( f \wedge g \) denote the induced map

\[
(A \otimes B') \coprod_{A \otimes B} (A' \otimes B) \to A' \otimes B'.
\]

We observe that the operation \( \wedge \) determines a symmetric monoidal structure on the category of morphisms in \( \mathbf{A} \). In particular, for every morphism \( f : X \to Y \), we iterate the above construction to obtain a map

\[
\wedge^n(f) : \square^n(f) \to Y^\otimes n.
\]

Here the source and target of \( \wedge^n(f) \) carry actions of the symmetric group \( \Sigma_n \), and \( \wedge^n(f) \) is a \( \Sigma_n \)-equivariant map. Passing to \( \Sigma_n \)-coinvariants, we obtain a new map, which we will denote by \( \sigma^n(f) : \text{Sym}^n(Y; X) \to \text{Sym}^n(Y) \).

Before giving the next definition, we need to review a bit of terminology. Recall that a collection \( S \) of morphisms in a presentable category \( \mathbf{A} \) is weakly saturated if it is stable under pushouts, retracts, and transfinite composition (see Definition T.A.1.2.2). For every collection \( S \) of morphisms in \( \mathbf{A} \), there is a smallest weakly saturated collection of morphisms \( \overline{S} \) containing \( S \). In this case, we will say that \( \overline{S} \) is generated by \( S \).
Definition 4.5.4.2. Let $\mathbf{A}$ be a combinatorial symmetric monoidal model category. We will say that a morphism $f : X \rightarrow Y$ is a \textit{power cofibration} if the following condition is satisfied:

\((\star)\) For every $n \geq 0$, the induced map $\wedge^n(f) : \square^n(f) \rightarrow Y^\otimes n$ is a cofibration in $\mathbf{A}^\Sigma_n$. Here $\mathbf{A}^\Sigma_n$ denotes the category of objects of $\mathbf{A}$ equipped with an action of the symmetric group $\Sigma_n$, endowed with the \textit{projective} model structure (see §T.A.3.3).

We will say that an object $X \in \mathbf{A}$ is \textit{power cofibrant} if the map $\emptyset \rightarrow X$ is a power cofibration, where $\emptyset$ is an initial object of $\mathbf{A}$.

Let $V$ be a collection of morphisms in a combinatorial symmetric monoidal model category $\mathbf{A}$. We will say that $\mathbf{A}$ is \textit{freely powered} if the following conditions are satisfied:

\((F1)\) The model category $\mathbf{A}$ satisfies the monoid axiom of [128] (see Definition 4.1.4.1): if $\mathcal{U}$ denotes the weakly saturated class generated by morphisms of the form $\text{id}_X \otimes f$, where $f$ is a trivial cofibration in $\mathbf{A}$, then every morphism in $\mathcal{U}$ is a weak equivalence in $\mathbf{A}$.

\((F2)\) The model category $\mathbf{A}$ is left proper, and the collection of cofibrations in $\mathbf{A}_V$ is generated (as a weakly saturated class) by cofibrations between cofibrant objects.

\((F3)\) Every cofibration in $\mathbf{A}$ is a power cofibration.

Remark 4.5.4.3. If $f : X \rightarrow Y$ is a cofibration in $\mathbf{A}$, then the definition of a monoidal model category guarantees that $\wedge^n(f)$ is a cofibration in $\mathbf{A}$, which is trivial if $f$ is trivial. Condition $(\star)$ is much stronger: roughly speaking, it guarantees that the symmetric group $\Sigma_n$ acts \textit{freely} on the object $Y^\otimes n$ (see Lemma 4.5.4.11 below).

Remark 4.5.4.4. In the situation of Definition 4.5.4.2, if every object of $\mathbf{A}$ is cofibrant, then conditions $(F1)$ and $(F2)$ are automatic.

Remark 4.5.4.5. Let $\mathbf{A}$ be a combinatorial symmetric monoidal model category. Then every power cofibration in $\mathbf{A}$ is a cofibration (take $n = 1$).

We now turn to the study of commutative algebras in a symmetric monoidal model category $\mathbf{A}$. Let $\text{CAlg}(\mathbf{A})$ denote the category whose objects are commutative algebras in $\mathbf{A}$. The main results of this section can be stated as follows:

Proposition 4.5.4.6. Let $\mathbf{A}$ be a combinatorial symmetric monoidal model category which is freely powered. Then:

\((1)\) The category $\text{CAlg}(\mathbf{A})$ admits a combinatorial model structure, where:

\((W)\) A morphism $f : A \rightarrow B$ of commutative algebra objects of $\mathbf{A}$ is a weak equivalence if it is a weak equivalence when regarded as a morphism in $\mathbf{A}$.

\((F)\) A morphism $f : A \rightarrow B$ of commutative algebra objects of $\mathbf{A}$ is a fibration if it is a fibration when regarded as a morphism in $\mathbf{A}$.

\((2)\) The forgetful functor $\theta : \text{CAlg}(\mathbf{A}) \rightarrow \mathbf{A}$ is a right Quillen functor.

Theorem 4.5.4.7. Let $\mathbf{A}$ be a combinatorial symmetric monoidal model category which is freely powered. Assume that the forgetful functor $\theta : \text{CAlg}(\mathbf{A}) \rightarrow \mathbf{A}$ preserves fibrant-cofibrant objects. Let $\mathbf{A}^c$ and $\text{CAlg}(\mathbf{A})^c$ denote the full subcategories of $\mathbf{A}$ and $\text{CAlg}(\mathbf{A})$ spanned by the cofibrant objects, let $W$ be the collection of weak equivalences in $\mathbf{A}^c$, and let $W'$ be the collection of weak equivalences in $\text{CAlg}(\mathbf{A})^c$. Then the canonical map

$$\text{N}(\text{CAlg}(\mathbf{A})^c)[W'^{-1}] \rightarrow \text{CAlg}(\text{N}(\mathbf{A}^c)[W^{-1}])$$

is an equivalence of $\infty$-categories.
We will prove Proposition 4.5.4.6 and Theorem 4.5.4.7 at the end of this section.

Remark 4.5.4.8. Suppose that \( A \) is a combinatorial simplicial symmetric monoidal model category, in the sense of Definition 4.1.3.8. The category \( \text{CAlg}(A) \) inherits the structure of a simplicial category from \( A \): namely, we regard \( \text{CAlg}(A) \) as cotensored over simplicial sets using the observation that any commutative algebra structure on an object \( A \in A \) induces a commutative algebra structure on \( A^k \) for every simplicial set \( K \). It is not difficult to see that the model structure of Proposition 4.5.4.6 is compatible with this simplicial structure on \( \text{CAlg}(A) \).

Remark 4.5.4.9. Let \( \mathcal{C} \) be a symmetric monoidal \( \infty \)-category. In order for \( \mathcal{C} \) to arise from the situation described in Proposition 4.1.3.10, it is necessary for \( \mathcal{C} \) to be presentable and for the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) to preserve small colimits separately in each variable. We do not know if these conditions are also sufficient.

We now turn to the proof of Proposition 4.5.4.6. First, we need a few preliminaries.

Lemma 4.5.4.10. Let \( A \) be a combinatorial symmetric monoidal model category. For every category \( \mathcal{C} \), let \( A^\mathcal{C} \) denote the associated diagram category, endowed with the projective model structure (see \( \S 5.3.A.3 \)). Let \( f \) be a cofibration in \( A^\mathcal{C} \), and \( g \) a cofibration in \( A^\mathcal{C}' \). Then the smash product \( f \wedge g \) (see Notation 4.5.4.1) is a cofibration in \( A^{\mathcal{C} \times \mathcal{C}'} \). In particular, if \( X \in A^\mathcal{C} \) and \( Y \in A^\mathcal{C}' \) are cofibrant, then \( X \otimes Y \) is a cofibrant object of \( A^{\mathcal{C} \times \mathcal{C}'} \).

Proof. Let \( S \) denote the collection of all morphisms \( f \) in \( A^\mathcal{C} \) for which the conclusion of the Lemma holds. It is not difficult to see that \( S \) is weakly saturated, in the sense of Definition T.A.1.2. Consequently, it will suffice to prove that \( S \) contains a set of generating cofibrations for \( A^\mathcal{C} \). Let \( i^\mathcal{C} : \{ \ast \} \to \mathcal{C} \) be the inclusion of an object \( C \in \mathcal{C} \), and let \( i^\mathcal{C} : A \to A^\mathcal{C} \) be the corresponding left Kan extension functor (a left adjoint to the evaluation at \( C \)). Then the collection of cofibrations in \( A^\mathcal{C} \) is generated by morphisms of the form \( i^\mathcal{C} (f_0) \), where \( f_0 \) is a cofibration in \( A \). We may therefore assume that \( f = i^\mathcal{C} (f_0) \). Using the same argument, we may assume that \( g = i^\mathcal{C}' (g_0) \), where \( C' \in \mathcal{C} \) and \( g_0 \) is a cofibration in \( A \). We now observe that \( f \wedge g \) is isomorphic to \( i^\mathcal{C} \wedge i^\mathcal{C}' (f_0 \wedge g_0) \). Since \( i^\mathcal{C} \wedge i^\mathcal{C}' : A \to A^{\mathcal{C} \times \mathcal{C}'} \) is a left Quillen functor, it will suffice to show that \( f_0 \wedge g_0 \) is a cofibration in \( A \), which follows from our assumption that \( A \) is a (symmetric) monoidal model category.

Lemma 4.5.4.11. Let \( A \) be a combinatorial symmetric monoidal model category. Then:

1. Let \( f : X \to Y \) be a power cofibration in \( A \). Then the induced map
   \[
   \sigma^n(f) : \text{Sym}^n(Y; X) \to \text{Sym}^n(Y)
   \]
   is a cofibration, which is weak equivalence if \( f \) is a weak equivalence (see Notation 4.5.4.1) and \( n > 0 \).

2. Let \( Y \) be a power cofibrant object of \( A \). Then \( \text{Sym}^n(Y) \) is a homotopy colimit for the action of \( \Sigma_n \) on \( Y^{\otimes n} \).

3. Let \( f : X \to Y \) be a power cofibration between power-cofibrant objects of \( A \). Then the object \( \square^n(f) \in A^{\Sigma_n} \) is cofibrant (with respect to the projective model structure).

Proof. Let \( F : A^{\Sigma_n} \to A \) be a left adjoint to the diagonal functor, so that \( F \) carries an object \( X \in A^{\Sigma_n} \) to the object of coinvariants \( X_{\Sigma_n} \). We observe that \( F \) is a left Quillen functor, and that \( \sigma^n(f) = F(\wedge^n(f)) \) for every morphism in \( A \). Assertion (1) now follows immediately from the definitions (and the observation that \( \wedge^n(f) \) is a weak equivalence if \( n > 0 \) and \( f \) is a trivial cofibration). Assertion (2) follows immediately from the definition of a homotopy colimit.

We now prove (3). Let \( f : X \to Y \) be a power cofibration between power cofibrant objects of \( A \). We observe that \( Y^{\otimes n} \) admits a \( \Sigma_n \)-equivariant filtration
   \[
   X^{\otimes n} = Z_0 \xrightarrow{\gamma_1} Z_1 \xrightarrow{\gamma_2} \ldots \xrightarrow{\gamma_{n-1}} Z_{n-1} = \square^n(f) \to Z_n = Y^{\otimes n}.
   \]
It will therefore suffice to prove that each of the maps \( \{ \gamma_i \} \) is a cofibration in \( A^{\Sigma_n} \). For this, we observe that there is a pushout diagram

\[
\begin{array}{ccc}
\pi_1(\square'(f) \times X \otimes (n-i)) & \xrightarrow{\pi_1((\wedge_i(f)) \otimes \text{id})} & \pi_1(Y \otimes X \otimes n-i) \\
\downarrow & & \downarrow \\
Z_{i-1} & \xrightarrow{\gamma_i} & Z_i,
\end{array}
\]

where \( \pi_1 \) denotes the left adjoint to the forgetful functor \( A^{\Sigma_{n}} \to A^{\Sigma_{i} \times \Sigma_{n-i}} \). Since \( \pi_1 \) is a left Quillen functor, it suffices to show that each \( \wedge_i(f) \otimes \text{id} \) is a cofibration in \( A^{\Sigma_{i} \times \Sigma_{n-i}} \). This follows from our assumption that \( X \) is power cofibrant, our assumption that \( f \) is a power cofibration, and Lemma 4.5.4.10.

**Proof of Proposition 4.5.4.6.** We first observe that the category \( \text{CAlg}(A) \) is presentable (this is a special case of Corollary 3.2.3.5). Since \( A \) is combinatorial, there exists a (small) collection of morphisms \( \bar{I} = \{ i_\alpha : C \to C' \} \) which generates the class of cofibrations in \( A \), and a (small) collection of morphisms \( \bar{J} = \{ j_\alpha : D \to D' \} \) which generates the class of trivial cofibrations in \( A \).

Let \( F : A \to \text{CAlg}(A) \) be a left adjoint to the forgetful functor. Let \( \overline{F(\bar{I})} \) be the weakly saturated class of morphisms in \( \text{CAlg}(A) \) generated by \( \{ F(i) : i \in \bar{I} \} \), and let \( \overline{F(\bar{J})} \) be defined similarly. Unwinding the definitions, we see that a morphism in \( \text{CAlg}(A) \) is a trivial fibration if and only if it has the right lifting property with respect to \( F(i) \), for every \( i \in \bar{I} \). Invoking the small object argument, we deduce that every morphism \( f : A \to C \) in \( \text{CAlg}(A) \) admits a factorization \( A \xrightarrow{\ell'} B \xrightarrow{\ell''} C \) where \( \ell' \in \overline{F(\bar{I})} \) and \( \ell'' \) is a trivial fibration. Similarly, we can find an analogous factorization where \( \ell' \in \overline{F(\bar{J})} \) and \( \ell'' \) is a fibration.

Using a standard argument, we may reduce the proof of (1) to the problem of showing that every morphism belonging to \( \overline{F(\bar{J})} \) is a weak equivalence in \( \text{CAlg}(A) \). Let \( \overline{U} \) be as in Definition 4.5.4.2, and let \( S \) be the collection of morphisms in \( \text{CAlg}(A) \) such that the underlying morphism in \( A \) belongs to \( \overline{U} \). Since \( A \) satisfies condition \( (F1) \), \( S \) consists of weak equivalences in \( A \). It will therefore suffice to show that \( \overline{F(\bar{J})} \subseteq S \). Because \( S \) is weakly saturated, it will suffice to show that \( F(\bar{J}) \subseteq S \). Unwinding the definitions, we are reduced to proving the following:

\( (\ast) \) Let

\[
\begin{array}{ccc}
F(C) & \xrightarrow{F(i)} & F(C') \\
\downarrow & & \downarrow \\
A & \xrightarrow{f} & A'
\end{array}
\]

be a pushout diagram in \( \text{CAlg}(A) \). If \( i \) is a trivial cofibration in \( A \), then \( f \in S \).

To prove \( (\ast) \), we observe that \( F(C') \) admits a filtration by \( F(C) \)-modules

\[
F(C) \simeq B_0 \to B_1 \to B_2 \to \ldots,
\]

where \( F(C') \simeq \text{colim}\{B_i\} \) and for each \( n > 0 \) there is a pushout diagram

\[
\begin{array}{ccc}
F(C) \otimes \text{Sym}^n(C';C) & \xrightarrow{\text{id}_{F(C)} \otimes \text{Sym}^n(i)} & F(C) \otimes \text{Sym}^n(C') \\
\downarrow & & \downarrow \\
B_{n-1} & \xrightarrow{} & B_n.
\end{array}
\]

(See Notation 4.5.4.1.) It follows that \( A' \) admits a filtration by \( A \)-modules

\[
A \simeq B'_0 \to B'_1 \to B'_2 \to \ldots,
\]
where $A' \simeq \text{colim}\{B'_i\}$ and for each $n > 0$ there is a pushout diagram

$$
\begin{array}{ccc}
A \otimes \text{Sym}^n(C'; C) & \xrightarrow{\text{id}_A \otimes \sigma^n(i)} & A \otimes \text{Sym}^n(C') \\
\downarrow & & \downarrow \\
B_{n-1} & \longrightarrow & B'_n.
\end{array}
$$

Since $i$ is a trivial power cofibration, Lemma 4.5.4.11 implies that $\sigma^n(i)$ is a trivial cofibration in $A$. It follows that $\text{id}_A \otimes \sigma^n(i)$ belongs to $U$. Since $U$ is stable under transfinite composition, we conclude that $f$ belongs to $S$. This completes the proof of (1). Assertion (2) is obvious. \hfill $\Box$

The proof of Theorem 4.5.4.7 rests on the following analogue of Lemma 4.1.4.13:

**Lemma 4.5.4.12.** Let $A$ be as in Theorem 4.5.4.7, and let $\mathcal{C}$ be a small category such that $N(\mathcal{C})$ is sifted (Definition T.5.5.8.1). Then the forgetful functor $N(C\text{Alg}(A))^\mathcal{C}[W^{-1}] \to N(A^\mathcal{C})[W^{-1}]$ preserves $N(\mathcal{C})$-indexed colimits.

**Proof.** In view of Propositions 1.3.4.24 and 1.3.4.25, it will suffice to prove that the forgetful functor $\theta : C\text{Alg}(A) \to A$ preserves homotopy colimits indexed by $\mathcal{C}$. Let us regard $C\text{Alg}(A)^{\mathcal{C}}$, $A^{\mathcal{C}}$, and $A^\mathcal{C}$ as endowed with the projective model structure (see §T.A.3). Let $F : A^{\mathcal{C}} \to A$ and $F_{\text{CAlg}} : C\text{Alg}(A)^{\mathcal{C}} \to C\text{Alg}(A)$ be colimit functors, and let $\theta^\mathcal{C} : C\text{Alg}(A)^{\mathcal{C}} \to A^\mathcal{C}$ be given by composition with $\theta$. Since $N(\mathcal{C})$ is sifted, there is a canonical isomorphism of functors $\alpha : F \circ \theta^\mathcal{C} \simeq \theta \circ F_{\text{CAlg}}$. We wish to prove that this isomorphism persists after deriving all of the relevant functors. Since $\theta$ and $\theta^\mathcal{C}$ preserve weak equivalences, they can be identified with their right derived functors. Let $LF$ and $LF_{\text{CAlg}}$ be the left derived functors of $F$ and $F_{\text{CAlg}}$, respectively. Then $\alpha$ induces a natural transformation $\overline{\pi} : LF \circ \theta^\mathcal{C} \to \theta \circ LF_{\text{CAlg}}$; we wish to show that $\overline{\pi}$ is an isomorphism. Let $A : \mathcal{C} \to C\text{Alg}(A)$ be a projectively cofibrant object of $C\text{Alg}(A)^{\mathcal{C}}$; we must show that the natural map

$$
LF(\theta^\mathcal{C}(A)) \to \theta(LF_{\text{CAlg}}(A)) \simeq \theta(F_{\text{CAlg}}(A)) \simeq F(\theta^\mathcal{C}(A))
$$

is a weak equivalence in $A$.

Let us say that an object $X \in A^\mathcal{C}$ is good if each $X(C) \in A$ is cofibrant, the colimit $F(X) \in A$ is cofibrant, and the canonical map the natural map $LF(X) \to F(X)$ is an isomorphism in the homotopy category $hA$ (in other words, the colimit of $X$ is also a homotopy colimit of $X$). To complete the proof, it will suffice to show that $\theta^\mathcal{C}(A)$ is good, whenever $A$ is a projectively cofibrant object of $C\text{Alg}(A)^{\mathcal{C}}$. This is not obvious, since $\theta^\mathcal{C}$ is a right Quillen functor and does not preserve projectively cofibrant objects in general (note that we have not yet used the full strength of our assumption that $N(\mathcal{C})$ is sifted). To continue the proof, we will need a relative version of the preceding condition. We will say that a morphism $f : X \to Y$ in $A^\mathcal{C}$ is good if the following conditions are satisfied:

(i) The objects $X, Y \in A^\mathcal{C}$ are good.

(ii) For each $C \in \mathcal{C}$, the induced map $X(C) \to Y(C)$ is a cofibration in $A$.

(iii) The map $F(X) \to F(Y)$ is a cofibration in $A$.

As in the proof of Lemma 4.1.4.13, we have the following:

(1) The collection of good morphisms is stable under transfinite composition.

(2) Suppose given a pushout diagram

$$
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow & & \downarrow \\
X' & \xrightarrow{f'} & Y'
\end{array}
$$

in $A^\mathcal{C}$. If $f$ is good and $X'$ is good, then $f'$ is good.
Let $F : \mathcal{C} \to \mathbf{A}$ be a constant functor whose value is a cofibrant object of $\mathbf{A}$. Then $F$ is good.

Every projectively cofibrant object of $\mathbf{A}^C$ is good. Every strong cofibration between projectively cofibrant objects of $\mathbf{A}^C$ is good.

If $X$ and $Y$ are good objects of $\mathbf{A}^C$, then $X \otimes Y$ is good.

Let $f : X \to X'$ be a good morphism in $\mathbf{A}^C$, and let $Y$ be a good object of $\mathbf{A}^C$. Then the morphism $f \otimes \text{id}_Y$ is good.

Let $f : X \to X'$ and $g : Y \to Y'$ be good morphisms in $\mathbf{A}^C$. Then

$$f \land g : (X \otimes Y') \coprod_{X \otimes Y} (X' \otimes Y) \to X' \otimes Y'$$

is good.

Moreover, our assumption that $\mathbf{A}$ is freely powered ensures that the class of good morphisms has the following additional property:

Let $f : X \to Y$ be a good morphism in $\mathbf{A}^C$. Then the induced map $\sigma^n(f) : \text{Sym}^n(Y; X) \to \text{Sym}^n(Y)$ (see Notation 4.5.4.1) is good. Condition (ii) follows immediately from Lemma 4.5.4.11, and condition (iii) follows from Lemma 4.5.4.11 and the observation that $F(\sigma^n(f)) = \sigma^n(F(f))$ (since the functor $F$ commutes with colimits and tensor products). It will therefore suffice to show that the objects $\text{Sym}^n(Y; X)$ and $\text{Sym}^n(Y)$ are good. Let $D : \mathbf{A}^\Sigma_n \to \mathbf{A}$ be the coinvariants functor, and consider the following diagram of left Quillen functors (which commutes up to canonical isomorphism):

$$\begin{array}{ccc}
\mathbf{A}^{C \times \Sigma_n} & \xrightarrow{D^C} & \mathbf{A}^C \\
\downarrow F & & \downarrow F \\
\mathbf{A}^\Sigma_n & \xrightarrow{D} & \mathbf{A}.
\end{array}$$

Let us regard $\land^n(f)$ as an object in the category of arrows of $h\mathbf{A}^{C \times \Sigma_n}$. We wish to show that the canonical map $LF(\sigma^n(f)) \to F(\sigma^n(f))$ is an isomorphism (in the category of morphisms in $h\mathbf{A}$). We now observe that $\sigma^n(f) = D^C(\land^n(f))$. Lemma 4.5.4.11 implies that the canonical map $LD^C \land^n(f) \to D^C \land^n(f)$ is a weak equivalence. It will therefore suffice to show that the transformation

$$\alpha : L(F \circ D^C)(\land^n(f)) \to (F \circ D^C)(\land^n(f))$$

is an isomorphism (in the category of morphisms of $h\mathbf{A}$). Using the commutativity of the above diagram, we can identify $\alpha$ with the map

$$(LD \circ LF) \land^n(f) \to (D \circ F)(\land^n(f)) = D \land^n(F(f)).$$

Using Lemma 4.5.4.11 again, we can identify the right hand side with $LD \land^n(F(f))$. It will therefore suffice to show that the map $LF \land^n(f) \to F \land^n(f)$ is an isomorphism in the category of morphisms of $h\mathbf{A}^\Sigma_n$. Since the forgetful functor $\mathbf{A}^\Sigma_n \to \mathbf{A}$ preserves homotopy colimits (it is also a left Quillen functor) and detects equivalences, we are reduced to proving that the morphism $\land^n(f)$ is good. This follows from (7) using induction on $n$.

We observe that axiom $(F2')$ of Definition 4.5.4.2 has the following consequence:

$(F2')$ The collection of all projective cofibrations in $\mathbf{A}^C$ is generated by projective cofibrations between projectively cofibrant objects.
Let \( T : \mathbf{A}^e \to \text{CAlg}(\mathbf{A})^e \) be a left adjoint to \( \theta^e \). Using the small object argument and \((B')\), we conclude that for every projectively cofibrant object \( A \in \text{CAlg}(\mathbf{A})^e \) there exists a transfinite sequence \( \{ A^\beta \}_{\beta \leq \alpha} \) in \( \text{CAlg}(\mathbf{A})^e \) with the following properties:

(a) The object \( A^0 \) is initial in \( \text{CAlg}(\mathbf{A})^e \).

(b) The object \( A \) is a retract of \( A^\alpha \).

(c) If \( \lambda \leq \alpha \) is a limit ordinal, then \( A^\lambda \simeq \text{colim} \{ A^\beta \}_{\beta < \lambda} \).

(d) For each \( \beta < \alpha \), there is a pushout diagram

\[
\begin{array}{ccc}
T(X') & \xrightarrow{T(f)} & T(X) \\
\downarrow & & \downarrow \\
A^\beta & \rightarrow & A^{\beta+1}
\end{array}
\]

where \( f \) is a projective cofibration between projectively cofibrant objects of \( \mathbf{A}^e \).

We wish to prove that \( \theta^e(A) \) is good. In view of (b), it will suffice to show that \( \theta^e(A^\alpha) \) is good. We will prove a more general assertion: for every \( \gamma \leq \beta \leq \alpha \), the induced morphism \( u_{\gamma, \beta} : \theta^e(A^\gamma) \to \theta^e(A^\beta) \) is good. The proof is by induction on \( \beta \). If \( \beta = 0 \), then we are reduced to proving that \( \theta^e(A^0) \) is good. This follows from (a) and (3). If \( \beta \) is a nonzero limit ordinal, then the desired result follows from (c) and (1). It therefore suffices to treat the case where \( \beta = \beta' + 1 \) is a successor ordinal. Moreover, we may suppose that \( \gamma = \beta' \): if \( \gamma < \beta' \), then we observe that \( u_{\gamma, \beta} = u_{\beta', \beta} \circ u_{\gamma, \beta'} \) and invoke (1), while if \( \gamma > \beta' \), then \( \gamma = \beta \) and we are reduced to proving that \( \theta^e(A^\beta) \) is good, which follows from the assertion that \( u_{\beta', \beta} \) is good. We are now reduced to proving the following:

(*) Let

\[
\begin{array}{ccc}
T(X') & \xrightarrow{T(f)} & T(X) \\
\downarrow & & \downarrow \\
B' & \xrightarrow{v} & B
\end{array}
\]

be a pushout diagram in \( \text{CAlg}(\mathbf{A})^e \), where \( f : X' \to X \) is a projective cofibration between projectively cofibrant objects of \( \mathbf{A}^e \). If \( \theta^e(B') \) is good, then \( \theta^e(v) \) is good.

To prove (*), we set \( Y = \theta^e(B) \in \mathbf{A}^e, Y' = \theta^e(B') \in \mathbf{A}^e \). Let \( g : \emptyset \to Y' \) the unique morphism, where \( \emptyset \) denotes an initial object of \( \mathbf{A}^e \). As in the proof of Proposition 4.5.4.6, \( Y \) can be identified with the colimit of a sequence

\[
Y' = Y^{(0)} \xrightarrow{w_1} Y^{(1)} \xrightarrow{w_2} \ldots
\]

where \( Y^{(0)} = Y' \), and \( w_k \) is a pushout of the morphism \( f^{(k)} = B' \otimes \sigma^k(f) \). The desired result now follows immediately from (4), (6) and (8).

We are now ready to prove our main result:

**Proof of Theorem 4.5.4.7.** Consider the diagram

\[
\begin{array}{ccc}
\text{N}(\text{CAlg}(\mathbf{A})^e)[W^{-1}] & \xrightarrow{\gamma'} & \text{CAlg}(\text{N}(\mathbf{A}^e)[W^{-1}]) \\
\downarrow & & \text{CAlg}(\text{N}(\mathbf{A}^e)[W^{-1}]) \\
\text{N}(\mathbf{A}^e)[W^{-1}] & \xleftarrow{\gamma} & \text{N}(\mathbf{A}^e)[W^{-1}]
\end{array}
\]

It will suffice to show that this diagram satisfies the hypotheses of Corollary 4.7.4.16:
(a) The $\infty$-categories $N(CAlg(A)^c)[W^{-1}]$ and $CAlg(N(A^c)[W^{-1}])$ admit geometric realizations of simplicial objects. In fact, both of these $\infty$-categories are presentable. For $N(CAlg(A)^c)[W^{-1}]$, this follows from Propositions 1.3.4.22 and 4.5.4.6. For $CAlg(N(A^c)[W^{-1}])$, we first observe that $N(A^c)[W^{-1}]$ is presentable (Proposition 1.3.4.22) and that the tensor product preserves colimits separately in each variable (Corollary 4.1.4.8), and then apply Corollary 3.2.3.5.

(b) The functors $G$ and $G'$ admit left adjoints $F$ and $F'$. The existence of a left adjoint to $G'$ follows from Corollary 3.1.3.5, and a left adjoint to $G$ is induced by the left Quillen functor $A \to CAlg(A)$.

(c) The functor $G'$ is conservative and preserves geometric realizations of simplicial objects. This follows from Corollary 3.2.3.2 and Lemma 3.2.2.6.

(d) The functor $G$ is conservative and preserves geometric realizations of simplicial objects. The first assertion is immediate from the definition of the weak equivalences in $CAlg(A)$, and the second follows from Lemma 4.5.4.12.

(e) The canonical map $G' \circ F' \to G \circ F$ is an equivalence of functors. Unwinding the definitions, we must show that for every cofibrant object $C \in A$, the free strictly commutative algebra $\coprod_n Sym^n(C) \in CAlg(A)$ is a free algebra generated by $C$, in the sense of Definition 3.1.3.1. In view of Proposition 3.1.3.13, it suffices to show that the colimit defining the total symmetric power $\coprod_n Sym^n(C)$ in $A$ is also a homotopy colimit. This follows immediately from part (3) of Lemma 4.5.4.11.

\[\square\]

4.6 Duality

Let $k$ be a field, and let $V$ be a vector space over $k$. The dual space $V^\vee$ is defined to be the set $\text{Hom}_k(V,k)$ of $k$-linear maps from $V$ into $k$. It can be characterized by the following universal property: for every $k$-vector space $W$, giving a $k$-linear map $W \to V^\vee$ is equivalent to giving a $k$-linear map $W \otimes_k V \to k$ (or, equivalently, a bilinear map $W \times V \to k$). In particular, the identity $id : V^\vee \to V^\vee$ classifies a linear map $e : V^\vee \otimes_k V \to k$, which corresponds to the bilinear map $(\lambda, v) \mapsto \lambda(v)$.

If $V$ is a finite-dimensional vector space over $k$, then the dual $V^\vee$ admits a second description: for every $k$-vector space $W$, the tensor product $W \otimes_k V^\vee$ can be identified with the set $\text{Hom}_k(W,V)$ of $k$-linear maps from $V$ into $W$. In particular, $V \otimes_k V^\vee$ can be identified with the set of $k$-linear endomorphisms of $V$, and there is a canonical map $e : k \to V \otimes_k V^\vee$ which carries the element $1 \in k$ to the identity endomorphism of $V$. It is not difficult to verify that the composite maps

\[V \simeq k \otimes_k V \xrightarrow{id \otimes_k V} V \otimes_k V^\vee \xrightarrow{id \otimes_k V} V \otimes_k k \simeq V\]

and

\[V^\vee \simeq V^\vee \otimes_k k \xrightarrow{id \otimes_k V^\vee} V^\vee \otimes_k V \otimes_k V^\vee \xrightarrow{id} k \otimes_k V^\vee \simeq V^\vee\]

correspond to the identity on $V$ and $V^\vee$, respectively.

In §4.6.1, we will generalize the duality theory of finite-dimensional vector spaces to the setting of an arbitrary monoidal $\infty$-category $\mathcal{C}$. For each object $X \in \mathcal{C}$, we introduce the notion of a right dual $X^\vee$ and a left dual $X^!$, and show that they are characterized uniquely (up to a contractible space of choices) when they exist (Lemma 4.6.1.10).

Suppose now that the monoidal $\infty$-category $\mathcal{C}$ admits geometric realizations of simplicial objects, which are preserved by the tensor product $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$. In this case, we can use the relative tensor product of §4.4.2 to introduce a relative theory of duality. In §4.6.2, we will generalize the notion of right and left dualizability to the setting of bimodule objects $M \in A BMod_B(\mathcal{C})$. Here the conditions of left and right dualizability are generally very different from one another: the left dual of $M$ can be viewed as an $A$-linear dual of $M$ (classifying $A$-linear maps from $M$ into $A$), while the right dual of $M$ can be viewed as a $B$-linear dual of $M$ (classifying $B$-linear maps from $M$ into $B$). In §4.6.4 we will study conditions on $A$ and $B$ which
allow us to relate these relative dualizability conditions to the dualizability of $M$ as an object of the ambient ∞-category $C$. Assume that $C$ is symmetric monoidal. We say that an algebra object $R \in \text{Alg}(C)$ is proper if it is dualizable when regarded as an object of $C$ (an important special case occurs when $R$ is self-dual as an object of $C$, which we will consider in §4.6.5). If $A$ is proper, then every left dualizable object of $\text{ABMod}_B(C)$ is dualizable as an object of $C$, and if $B$ is proper then every right dualizable object of $\text{ABMod}_B(C)$ is dualizable as an object of $C$ (Proposition 4.6.4.4). We also introduce the formally dual notion of a smooth algebra object of $C$, which allows us to prove converses to the above assertions. The definition of smoothness requires some elementary facts about the relationship between left and right modules, which we establish in §4.6.3.

### 4.6.1 Duality in Monoidal ∞-Categories

In this section, we will study the theory of duality in the setting of monoidal ∞-categories. We begin by reviewing some classical category theory.

**Definition 4.6.1.1.** Let $C$ be a monoidal category. A duality datum in $C$ consists of the following data:

1. A pair of objects $X, X^\vee \in C$.
2. A pair of morphisms
   \[ c : 1 \to X \otimes X^\vee \quad e : X^\vee \otimes X \to 1, \]
   where $1$ denotes the unit object of $C$.

These morphisms are required to satisfy the following conditions:

3. The composite maps
   \[ X \xrightarrow{c \otimes \text{id}_X} X \otimes X^\vee \otimes X \xrightarrow{\text{id}_X \otimes e} X \quad X^\vee \xrightarrow{\text{id}_{X^\vee} \otimes c} X^\vee \otimes X \otimes X^\vee \xrightarrow{e \otimes \text{id}_{X^\vee}} X^\vee \]
   are the identity on $X$ and $X^\vee$, respectively.

In this case, we will say that $e$ and $c$ exhibit $X^\vee$ as a right dual of $X$, or $X$ as a left dual of $X^\vee$.

Let $C$ be a monoidal ∞-category, and let $M$ be an ∞-category right-tensored over $C$. If $M, N \in M$ and $C \in C$, we will say that a morphism $q : N \otimes C \to M$ in $C$ exhibits $N$ as an exponential of $M$ by $C$ if, for every object $N' \in M$, the composite map
   \[ \text{Map}_M(N', N) \to \text{Map}_M(N' \otimes C, N \otimes C) \xrightarrow{q} \text{Map}_M(N' \otimes C, M) \]
   is a homotopy equivalence.

**Remark 4.6.1.2.** If $C$ and $M$ are presentable ∞-categories and the tensor product $M \times C \to M$ preserves colimits separately in each variable, then for every object $(M, C) \in M \times C^{op}$, the construction $N \mapsto \text{Map}_C(N \otimes C, M)$ determines a limit-preserving functor $M^{op} \to \mathcal{S}$, which is representable by an object $M^C \in M$ (Proposition T.5.5.2.2). By definition, this object is equipped with a canonical map $M^C \otimes C \to M$ which exhibits $M^C$ as an exponential of $M$ by $C$.

**Remark 4.6.1.3.** Let $C$ be a monoidal ∞-category and $M$ an ∞-category right-tensored over $C$. The construction $(M, C) \mapsto \text{Map}_C(\bullet \otimes C, M)$ determines a functor $\chi : M \times C^{op} \to \text{Fun}(M^{op}, \mathcal{S})$. Suppose that, for every object $(M, C) \in M \times C^{op}$, there exists an exponential $M^C \in M$. Then $\chi$ factors through the essential image of the Yoneda embedding $j : M \to \text{Fun}(M^{op}, \mathcal{S})$. Since $j$ is fully faithful, we can write $\chi \simeq j \circ \chi_0$ for some functor $\chi_0 : M \times C^{op} \to M$. We will denote this functor by $(M, C) \mapsto M^C$.

**Remark 4.6.1.4.** Let $C$ be as in Remark 4.6.1.3 and let $C \in C$. Then the functor $M \mapsto M^C$ preserves all limits which exist in $C$. 

Lemma 4.6.1.5. Let $\mathcal{C}$ be a monoidal $\infty$-category and let $\mathcal{M}$ be an $\infty$-category right-tensored over $\mathcal{C}$. Suppose that we are given a duality datum $(X, X^\vee, e, c)$ in the homotopy category $\mathcal{h}\mathcal{C}$. Then, for every object $M \in \mathcal{M}$, the map

$$(M \otimes X^\vee) \otimes X \simeq M \otimes (X^\vee \otimes X) \xrightarrow{\zeta} M \otimes 1 \simeq M$$

exhibits $M \otimes X^\vee$ as an exponential of $M$ by $X$.

Proof. Fix an object $N \in \mathcal{M}$. We wish to show that the composite map

$$\phi: \text{Map}_\mathcal{M}(N, M \otimes X^\vee) \to \text{Map}_\mathcal{M}(N \otimes X, M \otimes X^\vee \otimes X) \xrightarrow{\zeta} \text{Map}_\mathcal{M}(N \otimes X, M)$$

is a homotopy equivalence. Let $\psi$ denote the composition

$$\text{Map}_\mathcal{M}(N \otimes X, M) \to \text{Map}_\mathcal{M}(N \otimes X \otimes X^\vee, M \otimes X^\vee) \xrightarrow{\zeta} \text{Map}_\mathcal{M}(N, M \otimes X^\vee).$$

Using the compatibility of $e$ and $c$, we deduce that $\phi$ and $\psi$ are homotopy inverse to one another. $\square$

Lemma 4.6.1.6. Let $\mathcal{C}$ be a monoidal $\infty$-category and let $e: B \otimes C \to 1$ be a morphism in $\mathcal{C}$. The following conditions are equivalent:

1. The triple $(B, C, e)$ can be extended to a duality datum in the homotopy category $\mathcal{h}\mathcal{C}$. That is, there exists a map $c: 1 \to C \otimes B$ such that the compositions

$$C \to C \otimes B \to C \quad C \to C \otimes B \otimes C \to C$$

are homotopic to the identity.

2. For every object $A \in \mathcal{C}$, the map

$$A \otimes B \otimes C \xrightarrow{\text{id} \otimes e} A$$

exhibits $A \otimes B$ as an exponential of $A$ by $C$. In other words, for every object $D \in \mathcal{C}$, $e$ induces a homotopy equivalence

$$\text{Map}_\mathcal{C}(D, A \otimes B) \to \text{Map}_\mathcal{C}(D \otimes C, A).$$

Proof. The implication (1) $\Rightarrow$ (2) follows from Lemma 4.6.1.5 (applied to the right action of $\mathcal{C}$ on itself). Conversely, suppose that (2) is satisfied. Then the map

$$\theta: \text{Map}_\mathcal{C}(1, C \otimes B) \xrightarrow{\text{id} \otimes c} \text{Map}_\mathcal{C}(C, C \otimes B \otimes C) \xrightarrow{e} \text{Map}_\mathcal{C}(1, C)$$

is a homotopy equivalence. In particular, there exists a map $c: 1 \to C \otimes B$ whose image under $\theta$ is an equivalence. It follows that the composition

$$\phi: C \xrightarrow{c \otimes \text{id}} C \otimes B \otimes C \xrightarrow{\text{id} \otimes \zeta} C$$

is homotopic to the identity. To complete the proof, it suffices to show that the composition

$$\psi: B \xrightarrow{\text{id} \otimes \zeta} B \otimes C \otimes B \xrightarrow{e \otimes \text{id}} B$$

is homotopic to the identity. Assumption (2) (applied in the case $A = 1$) guarantees that $e$ exhibits $B$ as an exponential $1^C$, so that $\psi'$ is classified by up to homotopy by some map $e': B \otimes C \to 1$; we wish to prove that $e = e'$. Unwinding the definitions, we see that $e'$ is given by the composition

$$B \otimes C \xrightarrow{\text{id} \otimes \text{id}} B \otimes C \otimes B \otimes C \xrightarrow{\zeta} 1 \otimes 1 \xrightarrow{1} 1.$$

This map can be written as the composition

$$B \otimes C \xrightarrow{\text{id} \otimes \psi} B \otimes C \xrightarrow{e} 1,$$

which is homotopic to $e$ since $\phi$ is homotopic to $\text{id}_Y$. $\square$
Definition 4.6.1.7. Let $\mathcal{C}$ be a monoidal $\infty$-category. We say that an object $C \in \mathcal{C}$ is right dualizable (left dualizable) if there exists an object $B \in \mathcal{C}$ and a map $e : B \otimes C \to 1$ ($e : C \otimes B \to 1$) satisfying the equivalent conditions of Lemma 4.6.1.6. In this case, we will say that $e$ exhibits $B$ as a right (left) dual of $C$.

Notation 4.6.1.8. Let $\mathcal{C}$ be a monoidal $\infty$-category. We let $\text{DDat}(\mathcal{C})$ denote the full subcategory of

$$(\mathcal{C} \times \mathcal{C}) \times_{\text{Fun}(\{0\}, \mathcal{C})} \text{Fun}(\Delta^1, \mathcal{C}) \times_{\text{Fun}(\{1\}, \mathcal{C})} \{1\}$$

spanned by those triples $(B, C, e : B \otimes C \to 1)$ which satisfy the equivalent conditions of Lemma 4.6.1.6. We will refer to $\text{DDat}(\mathcal{C})$ as the $\infty$-groupoid of duality data in $\mathcal{C}$.

Remark 4.6.1.9. We observe that the image of $\pi$ is contained in the subcategory $\mathcal{C}^{rd} \subseteq \mathcal{C}$ whose objects are right dualizable objects of $\mathcal{C}$ and whose morphisms are equivalences in $\mathcal{C}$. The condition on objects follows from Lemma 4.6.1.6. The condition on morphisms follows from the following observation: if $\alpha : (B, C, e) \to (B', C', e')$ is a morphism in $\text{DDat}(\mathcal{C})$, then dual of the underlying map $C \to C'$ is a homotopy inverse to the underlying map $B \to B'$.

Lemma 4.6.1.10. Let $\mathcal{C}$ be a monoidal $\infty$-category and let $\mathcal{C}^{rd}$ be defined as in Remark 4.6.1.9. Then the map $\pi : \text{DDat}(\mathcal{C}) \to \mathcal{C}^{rd}$ is a trivial Kan fibration.

Proof. The map $\pi$ is obviously an essentially surjective categorical fibration. To show that it is an equivalence, it suffices to prove that $\pi$ is fully faithful. In other words, we must show that for every pair of objects $(B, C, e), (B', C', e') \in \mathcal{C}$, the map $\pi$ induces a homotopy equivalence $\text{Map}_{\text{DDat}(\mathcal{C})}(\pi(B, C, e), (B', C', e')) \to \text{Iso}_\mathcal{C}(B, B')$; here $\text{Iso}_\mathcal{C}(B, B')$ denotes the summand of the mapping space $\text{Map}_\mathcal{C}(X, X)$ consisting of those connected components which correspond to equivalences from $B$ to $B'$.

Unwinding the definitions, we see that $\text{Map}_{\text{DDat}(\mathcal{C})}(\pi(B, C, e), (B', C', e'))$ can be identified with the homotopy fiber of a map $\phi : \text{Iso}_\mathcal{C}(B, B') \times \text{Iso}_\mathcal{C}(C, C') \to \text{Map}_\mathcal{C}(B \otimes C, 1)$ over the point $e$. The pairings $e$ and $e'$ determine homotopy equivalences $\text{Iso}_\mathcal{C}(C, C') \simeq \text{Iso}_\mathcal{C}(B', B)$ and $\text{Map}_\mathcal{C}(B \otimes C, 1) \simeq \text{Map}_\mathcal{C}(B, B)$. Under these identifications, $\phi$ corresponds to the obvious composition map $\text{Iso}_\mathcal{C}(B, B') \times \text{Iso}_\mathcal{C}(B', B) \to \text{Map}_\mathcal{C}(B, B)$, and $\text{Map}_{\text{DDat}(\mathcal{C})}(\pi(B, C, e), (B', C', e'))$ corresponds to the homotopy fiber lying over the identity. Note that $\phi$ factors through the summand $\text{Iso}_\mathcal{C}(B, B')$. We have a homotopy pullback diagram

$$\begin{array}{ccc}
\text{Map}_{\text{DDat}(\mathcal{C})}(\pi(B, C, e), (B', C', e')) & \longrightarrow & \text{Iso}_\mathcal{C}(B, B') \times \text{Iso}_\mathcal{C}(B', B) \\
\downarrow & & \downarrow \psi \\
\text{Iso}_\mathcal{C}(B, B') & \longrightarrow & \text{Iso}_\mathcal{C}(B, B') \times \text{Iso}_\mathcal{C}(B, B),
\end{array}$$

where $\psi$ is given by the formula $(f, g) \mapsto (f, gf)$. It therefore suffices to show that $\psi$ is a homotopy equivalence, which is clear. \qed

Proposition 4.6.1.11. Let $\{\mathcal{C}_\alpha\}$ be a diagram of monoidal $\infty$-categories having a limit $\mathcal{C}$. Then an object of $\mathcal{C}$ is right dualizable if and only if its image in each $\mathcal{C}_\alpha$ is right dualizable.

Proof. The “only if” direction is obvious. For the converse, we observe that $\text{DDat}(\mathcal{C}) \cong \varprojlim \text{DDat}(\mathcal{C}_\alpha)$ and apply Lemma 4.6.1.10. \qed

Remark 4.6.1.12. If $\mathcal{C}$ is a symmetric monoidal $\infty$-category, then an object $C \in \mathcal{C}$ is left dualizable if and only if it is right dualizable; in this case, we will simply say that $C$ is dualizable.
4.6. DUALITY

4.6.2 Duality of Bimodules

Let \( \mathcal{C} \) be a monoidal \( \infty \)-category. In §4.6.1, we introduced the notion of the right dual of an object \( X \in \mathcal{C} \): that is, an object \( X^\vee \in \mathcal{C} \) equipped with evaluation and coevaluation maps

\[
e : X^\vee \otimes X \to 1 \quad c : X \otimes X^\vee \to 1
\]

for which the composite maps

\[
X \xrightarrow{e \otimes \text{id}} X \otimes X^\vee \otimes X \xrightarrow{\text{id} \otimes c} X
\]

\[
X^\vee \xrightarrow{\text{id} \otimes c} X^\vee \otimes X \otimes X^\vee \xrightarrow{e \otimes \text{id}} X^\vee
\]

are the identity on \( X \) and \( X^\vee \), respectively. In this section, we will discuss a generalization where we suppose that \( X \) is equipped with the structure of an \( A\text{-}B \)-bimodule, for some algebra objects \( A, B \in \text{Alg}(\mathcal{C}) \).

We begin by proving a counterpart to Lemma 4.6.1.6.

**Proposition 4.6.2.1.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category. Assume that \( \mathcal{C} \) admits geometric realizations of simplicial objects and that the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations of simplicial objects. Let \( A, B \in \text{Alg}(\mathcal{C}) \) and suppose we are given bimodule objects \( X \in A \text{-} \text{BMod}_B(\mathcal{C}) \), \( Y \in B \text{-} \text{BMod}_A(\mathcal{C}) \), and a morphism \( c : B \to Y \otimes_A X \) in \( B \text{-} \text{BMod}_B(\mathcal{C}) \). The following conditions are equivalent:

1. There exists a morphism \( e : X \otimes_B Y \to A \) in \( A \text{-} \text{BMod}_A(\mathcal{C}) \) such that the composite maps

\[
X \simeq X \otimes_B B \xrightarrow{\text{id} \otimes c} X \otimes_B Y \otimes_A X \xrightarrow{e \otimes \text{id}} A \otimes_A X \simeq X
\]

\[
Y \simeq B \otimes_B Y \xrightarrow{c \otimes \text{id}} Y \otimes_A X \otimes_B Y \xrightarrow{\text{id} \otimes e} Y \otimes_A A \simeq Y
\]

are homotopic to \( \text{id}_X \) and \( \text{id}_Y \), respectively.

2. Let \( \mathcal{M} \) be an \( \infty \)-category left-tensored over \( \mathcal{C} \) for that \( \mathcal{M} \) admits geometric realizations and the action map \( \mathcal{C} \times \mathcal{M} \to \mathcal{M} \) preserves geometric realizations. Let \( F : \text{LMod}_B(\mathcal{M}) \to \text{LMod}_A(\mathcal{M}) \) be the functor given by \( M \mapsto X \otimes_B M \), and let \( G : \text{LMod}_A(\mathcal{M}) \to \text{LMod}_B(\mathcal{M}) \) be the functor given by \( M \mapsto Y \otimes_A M \). Then the map \( c \) induces a natural transformation \( u : \text{id} \to G \circ F \) which exhibits \( F \) as left adjoint to \( G \).

3. Let \( \mathcal{N} \) be an \( \infty \)-category right-tensored over \( \mathcal{C} \) such that \( \mathcal{N} \) admits geometric realizations and the action map \( \mathcal{C} \times \mathcal{N} \to \mathcal{N} \) preserves geometric realizations. Let \( G : \text{RMod}_A(\mathcal{N}) \to \text{RMod}_B(\mathcal{N}) \) be the functor given by \( N \mapsto N \otimes_A X \), and let \( F : \text{RMod}_B(\mathcal{N}) \to \text{RMod}_A(\mathcal{N}) \) be the functor given by \( N \mapsto N \otimes_B Y \). Then the map \( c \) induces a natural transformation \( \text{id} \to G \circ F \) which exhibits \( F \) as left adjoint to \( G \).

**Proof.** We will prove the equivalence (1) \( \Leftrightarrow \) (2); the equivalence (1) \( \Leftrightarrow \) (3) will follow by symmetry. The implication (1) \( \Rightarrow \) (2) is obvious: if there exists a map \( e \) as in (1), then \( e \) induces a natural transformation \( v : F \circ G \to \text{id} \) which is a unit map compatible with the counit \( v \). Conversely, suppose that condition (2) is satisfied. Let \( \mathcal{M} = \text{RMod}_A(\mathcal{C}) \), which we regard as an \( \infty \)-category left-tensored over \( \mathcal{C} \) via the construction of §4.8.3. Regard \( A \) as an object of \( \text{LMod}_A(\mathcal{M}) \), let \( u : \text{id} \to G \circ F \) be as in (2), and choose a counit map \( \nu : F \circ G \to \text{id} \) compatible with \( u \). Then \( v \) induces a map \( v(A) : \text{id} \otimes_B Y \to A \). The compatibility between \( u \) and \( v \) implies that the composite map \( G \to (G \circ F) \circ G = G \circ (F \circ G) \) is homotopic to the identity. Evaluating on the object \( A \in \text{LMod}_A(\mathcal{M}) \), we conclude that the composite map

\[
\alpha : X \xrightarrow{e \otimes \text{id}} Y \otimes_A X \otimes_B Y \xrightarrow{\text{id} \otimes v(A)} Y
\]

is homotopic to \( \text{id}_Y \). To complete the proof, it will suffice to show that the map

\[
\beta : X \xrightarrow{\text{id} \otimes e} X \otimes_B Y \otimes_A X \xrightarrow{v(A) \otimes \text{id}} X
\]

is homotopic to \( \text{id}_X \). Let \( \mathcal{M}' = \text{RMod}_B(\mathcal{C}) \), and let

\[
F' : \text{LMod}_B(\mathcal{M}') \to \text{LMod}_A(\mathcal{M}') \quad G' : \text{LMod}_A(\mathcal{M}') \to \text{LMod}_B(\mathcal{M}')
\]
denote the functors given by tensor product with \( X \) and \( Y \), respectively. Let \( u' : \text{id}_{\text{LMod}_A(M')} \to G' \circ F' \) be the map described in (2). We regard \( B \) as an object of \( \text{LMod}_B(M') \), so that \( Y \simeq F'(B) \). Since \( u' \) is the unit of an adjunction, to show that \( \beta \) is homotopic to \( \text{id}_X \) it will suffice to show that the composite map

\[
B \xrightarrow{\varepsilon} (G' \circ F')(B) \simeq G'(X) \xrightarrow{G'\beta} G'(X) \simeq Y \otimes_A X
\]

is homotopic to \( c \). Unwinding the definitions, we see that this composition is given by

\[
B \simeq B \otimes_B B \xrightarrow{\varepsilon \otimes \varepsilon} Y \otimes_A X \otimes_B Y \otimes_A X \xrightarrow{\text{id} \otimes \varepsilon \otimes \text{id}} Y \otimes_A X.
\]

This map is homotopic to the composition

\[
B \xrightarrow{\varepsilon} Y \otimes_A X \xrightarrow{\text{id} \otimes \varepsilon} Y \otimes_A X
\]

and therefore also to \( c \), since \( \alpha \) is homotopic to \( \text{id}_Y \).

\[\square\]

**Remark 4.6.2.2.** In the setting of Proposition 4.6.2.1, it suffices to verify condition (2) in the special case where \( \mathcal{M} \) has the form \( \text{RMod}_r(\mathcal{C}) \) for some \( R \in \text{Alg}(\mathcal{C}) \): in fact, the proof requires only the special cases \( R = A \) and \( B = B \).

**Definition 4.6.2.3.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category which admits geometric realizations and for which the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations. Let \( A, B \in \text{Alg}(\mathcal{C}) \), let \( X \in _A \text{BMod}_B(\mathcal{C}) \), \( Y \in _B \text{BMod}_A(\mathcal{C}) \), and let \( c : B \to Y \otimes_A X \) be a map. We will say that \( c \) exhibits \( X \) as the right dual of \( Y \), or \( c \) exhibits \( Y \) as the left dual of \( X \), if the equivalent conditions of Proposition 4.6.2.1 are satisfied.

Given \( X \in _A \text{BMod}_B(\mathcal{C}) \), we will say that \( X \) is left dualizable if there exists an object \( Y \in _B \text{BMod}_A(\mathcal{C}) \) and a morphism \( c : B \to Y \otimes_A X \) which exhibits \( Y \) as a left dual of \( X \). Similarly, we say that an object \( Y \in _B \text{BMod}_A(\mathcal{C}) \) right dualizable if there exists an object \( X \in _A \text{BMod}_B(\mathcal{C}) \) and a morphism \( c : B \to Y \otimes_A X \) in \( _A \text{BMod}_B(\mathcal{C}) \) which exhibits \( X \) as a right dual of \( Y \).

**Example 4.6.2.4.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category and let \( 1 \) denote the unit object of \( \mathcal{C} \), regarded as a trivial algebra so that the forgetful functor \( _1 \text{BMod}_1(\mathcal{C}) \to \mathcal{C} \) is an equivalence of (monoidal) \( \infty \)-categories. An object \( X \in _1 \text{BMod}_1(\mathcal{C}) \) is left dualizable (right dualizable) in the sense of Definition 4.6.2.3 if and only if its image in \( \mathcal{C} \) is left dualizable (right dualizable) in the sense of Definition 4.6.1.7.

**Example 4.6.2.5.** Let \( \mathcal{C} \) be a monoidal \( \infty \)-category with unit object \( 1 \) (which we regard as a trivial algebra object of \( \mathcal{C} \)) and let \( A \in \text{Alg}(\mathcal{C}) \) be an algebra object of \( \mathcal{C} \). Suppose that \( c : 1 \to X \otimes X^\vee \) is a morphism in \( \mathcal{C} \) which exhibits \( X^\vee \) as a left dual of \( X \). Let us regard \( X \otimes A \) as an object of \( \text{RMod}_A(\mathcal{C}) \simeq _A \text{BMod}_1(\mathcal{C}) \) and \( A \otimes X^\vee \) as an object of \( \text{LMod}_A(\mathcal{C}) \simeq _A \text{BMod}_1(\mathcal{C}) \). Then the map

\[
c' : 1 \to X \otimes X^\vee \simeq X \otimes 1 \otimes X^\vee \to X \otimes A \otimes X^\vee \simeq (X \otimes A) \otimes_A (A \otimes X^\vee)
\]

in \( _A \text{BMod}_A(\mathcal{C}) \) exhibits \( A \otimes X^\vee \) as a left dual of \( X \otimes A \). To see this, choose a evaluation map \( e : X^\vee \otimes X \to 1 \) compatible with \( c \), and note that the map

\[
e' : (A \otimes X^\vee) \otimes (X \otimes A) \simeq A \otimes (X^\vee \otimes X) \otimes_A \text{id} \otimes e \otimes \text{id} \to A \otimes 1 \otimes A \simeq A \otimes A \to A
\]

satisfies condition (1) of Proposition 4.6.2.1.

**Remark 4.6.2.6.** In the situation of Definition 4.6.2.3, suppose that we are given algebra objects \( A, B, C \in \text{Alg}(\mathcal{C}) \) and bimodules \( M \in _A \text{BMod}_B(\mathcal{C}), N \in _B \text{BMod}_C(\mathcal{C}) \). If \( M \) and \( N \) are left dualizable (right dualizable), then the relative tensor product \( M \otimes_B N \) is left dualizable (right dualizable). Moreover, the left dual (right dual) of \( M \otimes_B N \) is given by \( N^* \otimes_B M^* \), where \( M^* \) and \( N^* \) denote the left duals (right duals) of \( M \) and \( N \), respectively.
Definition 4.6.2.7. Let \( p : \mathcal{M}^{\otimes} \to \mathcal{L}M^{\otimes} \) and \( q : \mathcal{N}^{\otimes} \to \mathcal{L}M^{\otimes} \) be coCartesian fibrations of \( \infty \)-operads, which exhibit \( \mathcal{M} = \mathcal{M}^{m}_m \) and \( \mathcal{N} = \mathcal{N}^{m}_m \) as left-tensored over the same monoidal \( \infty \)-category

\[
\mathcal{M}^{\otimes} \times_{\mathcal{L}M^{\otimes}} \text{Ass}^{\otimes} \cong \mathcal{C}^{\otimes} \otimes \mathcal{N}^{\otimes} \times_{\mathcal{L}M^{\otimes}} \text{Ass}^{\otimes}.
\]

A \( \mathcal{C} \)-linear functor from \( \mathcal{M} \) to \( \mathcal{N} \) is an \( \mathcal{L}M \)-monoidal functor from \( \mathcal{M}^{\otimes} \) to \( \mathcal{N}^{\otimes} \) which is the identity on \( \mathcal{C}^{\otimes} \). In other words, a \( \mathcal{C} \)-linear functor from \( \mathcal{M} \) to \( \mathcal{N} \) is a functor \( F : \mathcal{M}^{\otimes} \to \mathcal{N}^{\otimes} \) satisfying the following conditions:

(i) The diagram

\[
\begin{array}{ccc}
\mathcal{M}^{\otimes} & \xrightarrow{F} & \mathcal{N}^{\otimes} \\
p \downarrow & & \downarrow q \\
\mathcal{L}M^{\otimes} & \xrightarrow{} & \mathcal{M}^{\otimes}
\end{array}
\]

is commutative.

(ii) The functor \( F \) carries \( p \)-coCartesian morphisms of \( \mathcal{M}^{\otimes} \) to \( q \)-coCartesian morphisms of \( \mathcal{N}^{\otimes} \).

(iii) The restriction \( F|_{\mathcal{M}^{\otimes} \times_{\mathcal{L}M^{\otimes}} \text{Ass}^{\otimes}} \) is given by \( \beta \circ \alpha \).

We let \( \text{LinFun}_{\mathcal{C}}(\mathcal{M}, \mathcal{N}) \) denote the full subcategory of \( \text{Fun}_{\mathcal{L}M^{\otimes}}(\mathcal{M}^{\otimes}, \mathcal{N}^{\otimes}) \times_{\text{Fun}_{\mathcal{C}^{\otimes}}(\mathcal{C}^{\otimes}, \mathcal{C}^{\otimes})} \{\text{id}\} \) spanned by the \( \mathcal{C} \)-linear functors from \( \mathcal{M} \) to \( \mathcal{N} \).

Remark 4.6.2.8. In the situation of Definition 4.6.2.7, evaluation at \( m \in \mathcal{L}M \) determines a forgetful functor \( \theta : \text{LinFun}_{\mathcal{C}}(\mathcal{M}, \mathcal{N}) \to \text{Fun}(\mathcal{M}, \mathcal{N}) \). We will often abuse terminology by identifying \( F \) with the underlying functor \( \theta(F) : \mathcal{M} \to \mathcal{N} \).

Suppose that \( \mathcal{K} \) is a collection of simplicial sets such that both \( \mathcal{M} \) and \( \mathcal{N} \) admit \( \mathcal{K} \)-indexed colimits. We let \( \text{LinFun}_{\mathcal{K}}(\mathcal{M}, \mathcal{N}) \) denote the full subcategory of \( \text{LinFun}_{\mathcal{C}}(\mathcal{M}, \mathcal{N}) \) spanned by those functors \( F \) such that \( \theta(F) : \mathcal{M} \to \mathcal{N} \) preserves \( \mathcal{K} \)-indexed colimits.

Remark 4.6.2.9. Let \( \mathcal{C}^{\otimes} \) be a monoidal \( \infty \)-category, and let \( F : \mathcal{M}^{\otimes} \to \mathcal{N}^{\otimes} \) be a \( \mathcal{C} \)-linear functor from between \( \infty \)-categories left-tensored over \( \mathcal{C}^{\otimes} \). Then composition with \( F \) determines a commutative diagram

\[
\begin{array}{ccc}
\text{LMod}(\mathcal{M}) & \xrightarrow{} & \text{LMod}(\mathcal{N}) \\
\downarrow \quad \downarrow & & \downarrow \\
\text{Alg}(\mathcal{C}) & \xrightarrow{} & \text{LMod}(\mathcal{N})
\end{array}
\]

In particular, for every algebra object \( A \in \text{Alg}(\mathcal{C}) \), we have an induced functor \( \text{LMod}_A(\mathcal{M}) \to \text{LMod}_A(\mathcal{N}) \).

This construction depends functorially on \( F \) in an obvious sense, so we get a functor

\[
\text{LinFun}_{\mathcal{C}}(\mathcal{M}, \mathcal{N}) \to \text{Fun}(\text{LMod}_A(\mathcal{M}), \text{LMod}_A(\mathcal{N})).
\]

The following result gives a useful criterion for left dualizability:

Proposition 4.6.2.10. Let \( \mathcal{C} \) be a monoidal \( \infty \)-category which admits geometric realizations and for which the tensor product functor \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations. Let \( A, B \in \text{Alg}(\mathcal{C}) \) and let \( X \in \text{A}\text{BMod}_{\text{B}}(\mathcal{C}) \). Then \( X \) is left dualizable if and only if the following conditions are satisfied:

1. Let \( \mathcal{M} \) be an \( \infty \)-category right-tensored over \( \mathcal{M} \). Assume that \( \mathcal{M} \) admits geometric realizations and that the action \( \mathcal{M} \times \mathcal{C} \to \mathcal{M} \) preserves geometric realizations. Then the functor \( G_M : \text{RMod}_A(\mathcal{M}) \to \text{RMod}_B(\mathcal{M}) \), given by \( M \mapsto M \otimes_A X \), admits a left adjoint.
(2) Let \( U : \mathcal{M} \to \mathcal{M}' \) be a \( \mathbb{C} \)-linear functor between \( \infty \)-categories \( \mathcal{M} \) and \( \mathcal{M}' \) which are right-tensored over \( \mathbb{C} \) (see Definition 4.6.2.7). Assume that \( \mathcal{M} \) and \( \mathcal{M}' \) satisfy the hypotheses of (1) and that \( U \) preserves geometric realizations of simplicial objects. Then the diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\text{RMod}_A(\mathcal{M}) & \xrightarrow{G_M} & \text{RMod}_B(\mathcal{M}) \\
\downarrow & & \downarrow \\
\text{RMod}_A(\mathcal{M}') & \xrightarrow{G_{M'}} & \text{RMod}_B(\mathcal{M}')
\end{array}
\]

is left adjointable (Definition 4.7.5.13).

**Proof.** Assume first that \( X \) admits a left dual \( Y \in B\text{BMod}_A(\mathbb{C}) \), and let \( \mathcal{M} \) be as in (1). Then \( G_M \) admits a left adjoint \( F_M \), given informally by \( M \mapsto M \otimes_A Y \) (Proposition 4.6.2.1). This immediately implies (1), and assertion (2) follows from the formula for \( F_M \). Conversely, suppose that (1) and (2) are satisfied. Set \( \mathcal{M} = \text{LMod}_B(\mathbb{C}) \) and let \( F_M \) be the left adjoint to \( G_M \) whose existence is guaranteed by (1). We regard \( B \) as an object of \( \text{RMod}_B(\mathcal{M}) \) and let \( Y = F_M(B) \). Let \( u_M : \text{id} \to G_M \circ F_M \) be a unit for the adjunction between \( F_M \) and \( G_M \), so that \( u_M(A) \) can be regarded as a morphism \( c : B \to Y \otimes_A X \) in \( \text{RMod}_B(\mathcal{M}) \cong B\text{BMod}_B(\mathbb{C}) \). We will show that \( c \) exhibits \( Y \) as the left dual of \( X \) by verifying the analogue of condition (3) of Proposition 4.6.2.1. Let \( \mathcal{M}' \) be an \( \infty \)-category which is right-tensored over \( \mathbb{C} \), such that \( \mathcal{M}' \) admits geometric realizations and the action \( \mathcal{M}' \times \mathbb{C} \to \mathcal{M}' \) preserves geometric realizations of simplicial objects. Let \( T : \text{RMod}_B(\mathcal{M}') \to \text{RMod}_A(\mathcal{M}') \) be the functor given by \( M \mapsto M \otimes_B Y \), so that \( c \) determines a natural transformation \( u : \text{id}_{\text{RMod}_B(\mathcal{M}')} \to G_M \circ T \). Condition (1) guarantees that \( G_{M'} \) admits a right adjoint \( F_{M'} \), so that \( u \) determines a natural transformation \( \alpha : F_{M'} \to T \). We wish to show that \( \alpha \) is an equivalence. To this end, choose an object \( M \in \text{RMod}_B(\mathcal{M}') \); we wish to show that \( \alpha(M) : F_{M'}(M) \to M \otimes_B Y \) is an equivalence. The construction \( N \mapsto M \otimes_B N \) determines a \( \mathbb{C} \)-linear functor \( U : M = \text{LMod}_B(\mathbb{C}) \to \mathcal{M}' \) which carries \( B \in \text{RMod}_B(\mathcal{M}) \) to \( M \in \text{RMod}_B(\mathcal{M}') \) and commutes with geometric realizations (see Theorem 4.8.4.1 for a more detailed construction). The assertion that \( \alpha(M) \) is an equivalence now follows immediately from the left adjointability of the diagram

\[
\begin{array}{ccc}
\text{RMod}_A(\mathcal{M}) & \xrightarrow{G_M} & \text{RMod}_B(\mathcal{M}) \\
\downarrow & & \downarrow \\
\text{RMod}_A(\mathcal{M}') & \xrightarrow{G_{M'}} & \text{RMod}_B(\mathcal{M}')
\end{array}
\]

\[\blacksquare\]

**Remark 4.6.2.11.** Let \( \mathbb{C} \) be as in Proposition 4.6.2.10 and suppose that \( X \in A\text{BMod}_B(\mathbb{C}) \) satisfies conditions (1) and (2). Let \( G : A\text{BMod}_B(\mathbb{C}) \to B\text{BMod}_B(\mathbb{C}) \) be given by \( M \mapsto M \otimes_A X \), and let \( F \) be a left adjoint to \( G \). Suppose we are given a bimodule \( Y \in B\text{BMod}_A(\mathbb{C}) \) and a morphism \( c : B \to Y \otimes_A X \) in \( B\text{BMod}_B(\mathbb{C}) \). Then \( c \) exhibits \( Y \) as a left dual of \( X \) if and only if it is adjoint to an equivalence \( F(B) \to Y \in B\text{BMod}_A(\mathbb{C}) \). In particular, the left dual \( Y \) and the map \( c \) are determined (up to a contractible space of choices) provided that they exist.

**Remark 4.6.2.12.** Let \( \mathbb{C} \) be a monoidal \( \infty \)-category which admits geometric realizations and for which the tensor product \( \otimes : \mathbb{C} \times \mathbb{C} \to \mathbb{C} \) preserves geometric realizations. Suppose that \( X \in A\text{BMod}_B(\mathbb{C}) \), \( Y \in B\text{BMod}_A(\mathbb{C}) \), and \( c : X \otimes_B Y \to A \) is a map which exhibits \( Y \) as a left dual of \( X \). Let \( B' \to B \) be a morphism in \( \text{Alg}(\mathbb{C}) \), let \( X' \) denote the image of \( X \) in \( A\text{BMod}_B(\mathbb{C}) \), and let \( Y' \in B'\text{BMod}_A(\mathbb{C}) \) be defined similarly. Then the composite map

\[c' : X' \otimes_{B'} Y' \to X \otimes_B Y \xrightarrow{\iota} A\]

exhibits \( Y' \) as a left dual of \( X' \). To see this, choose a map \( c : B \to Y \otimes_A X \) as in Proposition 4.6.2.1. Note that \( Y' \otimes_A X' \) can be identified with the image of \( Y \otimes_A X \) under the forgetful functor \( B\text{BMod}_B(\mathbb{C}) \to \),
4.6. DUALITY

\_B \text{-BMod}_{B'}(\mathcal{C})\), so that \(c\) determines a morphism \(c' : B' \to B \to Y' \otimes_A X'\) in \(_B \text{-BMod}_{B'}(\mathcal{C})\). It is easy to see that \(c'\) satisfies the requirements of condition (1) of Proposition 4.6.2.1.

Using Proposition 4.6.2.10, we can prove a converse to Remark 4.6.2.12:

**Proposition 4.6.2.13.** Let \(\mathcal{C}\) be a monoidal \(\infty\)-category which admits geometric realizations and for which the tensor product functor \(\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}\) preserves geometric realizations. Let \(A, B \in \text{Alg}(\mathcal{C})\) and let \(X \in _A \text{BMod}_{B'}(\mathcal{C})\). The following conditions are equivalent:

(a) The object \(X\) is left dualizable.

(b) For every map \(B' \to B\) in \(\text{Alg}(\mathcal{C})\), the image of \(X\) in \(_A \text{BMod}_{B'}(\mathcal{C})\) is left dualizable.

(c) There exists a map \(B' \to B\) in \(\text{Alg}(\mathcal{C})\) such that the image of \(X\) in \(_A \text{BMod}_{B'}(\mathcal{C})\) is left dualizable.

(d) Let \(1\) denote the unit object of \(\mathcal{C}\), regarded as an initial object of \(\text{Alg}(\mathcal{C})\). Then the image of \(X\) in \(_{\text{LMod}} A(\mathcal{C}) \simeq _A \text{BMod}_{1}(\mathcal{C})\) is left dualizable.

**Proof.** The implication \((b) \Rightarrow (c)\) is obvious, and the implications \((a) \Rightarrow (b)\) and \((c) \Rightarrow (d)\) follow from Remark 4.6.2.12. We will show that \((d)\) implies \((a)\). Assume that the image of \(X\) in \(_{\text{LMod}} A(\mathcal{C})\) is left dualizable; we will show that \(X\) satisfies conditions (1) and (2) of Proposition 4.6.2.10.

We begin by verifying condition (1). Let \(M\) be an \(\infty\)-category right-tensored over \(\mathcal{C}\), and assume that the action \(M \times \mathcal{C} \to M\) preserves geometric realizations. Let \(G_M : \text{RMod}_A(M) \to \text{RMod}_B(M)\) be the functor given by tensor product with \(X\); we wish to show that \(G_M\) admits a left adjoint. Let \(\mathcal{X} \subseteq \text{RMod}_B(M)\) be the full subcategory spanned by those objects \(M\) for which the functor \(N \to \text{Map}_{\text{RMod}}(M, G_M(N))\) is corepresentable by an object of \(\text{RMod}_A(M)\); we wish to show that \(\mathcal{X} = \text{RMod}_B(M)\). Since \(\text{RMod}_A(M)\) admits geometric realizations of simplicial objects (Corollary 4.2.3.5), the \(\infty\)-category \(\mathcal{X}\) is closed under the formation of geometric realizations. It will therefore suffice to show that \(\mathcal{X}\) contains every free right module \(M_0 \otimes B\) (Corollary 4.7.4.14). In this case, the relevant functor is given by \(\text{Map}_{\mathcal{M}}(M_0, G(N))\), where \(G : \text{RMod}_A(M) \to M\) is the forgetful functor. The desired result now follows from the observation that \(G\) admits a left adjoint (by virtue of \((d)\) and Proposition 4.6.2.10).

The verification of condition (2) is similar. Suppose we are given a \(\mathcal{C}\)-linear functor \(U : M \to M'\) between \(\infty\)-categories right-tensored over \(\mathcal{C}\), which preserves geometric realizations. Let \(G_M\) and \(G_{M'}\) be defined as above; we wish to show that the diagram

\[
\begin{array}{ccc}
\text{RMod}_A(M) & \xrightarrow{G_M} & \text{RMod}_B(M) \\
\downarrow & & \downarrow \\
\text{RMod}_A(M') & \xrightarrow{G_{M'}} & \text{RMod}_B(M')
\end{array}
\]

is left adjointable. Let \(F_M\) and \(F_{M'}\) be the left adjoints to \(G_M\) and \(G_{M'}\), respectively, and let \(\mathcal{X}\) be the full subcategory of \(\text{RMod}_B(M)\) spanned by those objects \(M\) for which the map \(F_{M'}(UM) \to UF_M(M)\) is an equivalence. We wish to show that \(\mathcal{X} = \text{RMod}_B(M)\). It is easy to see that \(\mathcal{X}\) is closed under the formation of geometric realizations of simplicial objects; it will therefore suffice to show that \(\mathcal{X}\) contains every free right module of the form \(M_0 \otimes B\). This follows from the left adjointability of the outer square and rightmost square in the diagram

\[
\begin{array}{ccc}
\text{RMod}_A(M) & \xrightarrow{G_{M'}} & \text{RMod}_B(M') \\
\downarrow & & \downarrow \\
\text{RMod}_A(M') & \xrightarrow{G_{M'}} & \text{RMod}_B(M')
\end{array}
\]

which follow from \((d)\) and Proposition 4.6.2.10. \(\square\)
Remark 4.6.2.14. In the situation of Proposition 4.6.2.13, suppose we are given a map \( e : X \otimes_B Y \to A \). Suppose we are given a morphism \( B' \in \mathcal{E}(\mathcal{C}) \), and let \( X' \) and \( Y' \) denote the images of \( X \) and \( Y \) in \( _A\text{BMod}_B(\mathcal{E}) \) and \( _B\text{BMod}_A(\mathcal{E}) \), respectively. Then \( e \) exhibits \( X \) as a right dual of \( Y \) if and only if the composite map

\[
e' : X' \otimes_{B'} Y' \to X \otimes_B Y \xrightarrow{e} A
\]

exhibits \( X' \) as a right dual of \( Y' \). The “only if” direction follows from Remark 4.6.2.12. Conversely, suppose that \( e' \) exhibits \( X' \) as a right dual of \( Y' \). In particular, \( X' \) is left-dualizable, so that \( X \) is also left-dualizable by Proposition 4.6.2.13. It follows that \( e \) is classified by a morphism \( \theta : Y \to Y' \) in \( _B\text{BMod}_A(\mathcal{E}) \). Our assumption that \( e' \) is a duality datum guarantees that the image of \( \theta \) in \( _B\text{BMod}_A(\mathcal{E}) \) is an equivalence. It follows that \( \theta \) is an equivalence, so that \( e \) is also a duality datum.

Example 4.6.2.15. Let \( \mathcal{C} \) be as in Proposition 4.6.2.13. It follows from Proposition 4.6.2.13 and Example 4.6.2.5 that for any algebra object \( A \in \mathcal{E}(\mathcal{C}) \), \( A \) is (left and right) dualizable when viewed as a bimodule over itself.

Notation 4.6.2.16. Let \( \mathcal{C} \) be a monoidal \( \infty \)-category which admits geometric realizations and for which the tensor product functor \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations. If \( A \) is an associative algebra object of \( \mathcal{E} \), we let \( A_A \) denote its image under the map \( \mathcal{E}(\mathcal{C}) \to \text{BMod}(\mathcal{C}) \) given by composition with the forgetful functor \( \text{BMod} \to \text{Ass} \). Then \( A_A \) is both left and right dual to itself, via the homotopy inverse equivalences

\[
A_A \to A_A \otimes_A A_A \quad A_A \otimes_A A_A \to A_A.
\]

Given maps of algebra objects \( f : B \to A \), \( f' : C \to A \), we let \( B_A \) denote the image of \( A_A \) under the forgetful functor \( \text{BMod}_A(\mathcal{E}) \to \text{BMod}(\mathcal{E}) \) determined by \( f \) and \( f' \) (see Corollary 4.3.3.2). The bimodule object \( B_A \) is determined up to canonical equivalence by \( f \) and \( f' \). It follows from Remark 4.6.2.12 that the canonical map

\[
e : A_B \otimes_B B_A \to A_A \otimes_A A_A \simeq A
\]

exhibits \( A_B \) as a right dual of \( B_A \). Combining this observation with Proposition 4.6.2.1, we obtain the following:

Proposition 4.6.2.17. Let \( \mathcal{C} \) be a monoidal \( \infty \)-category and let \( \mathcal{M} \) be an \( \infty \)-category left-tensored over \( \mathcal{C} \). Assume that \( \mathcal{C} \) and \( \mathcal{M} \) admit geometric realizations of simplicial objects and that the tensor product functors

\[
\mathcal{C} \times \mathcal{C} \to \mathcal{C} \quad \mathcal{C} \times \mathcal{M} \to \mathcal{M}
\]

preserve geometric realizations of simplicial objects. Then, for every map \( f : B \to A \) in \( \mathcal{E}(\mathcal{C}) \), the forgetful functor \( \text{LMod}_A(\mathcal{M}) \to \text{LMod}_B(\mathcal{M}) \) admits a left adjoint, given by the relative tensor product construction \( M \mapsto A_B \otimes_B M \).

Let \( \mathcal{C} \) be a monoidal \( \infty \)-category which admits geometric realizations and for which the tensor product functor \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations, and let \( X \in _A\text{BMod}_B(\mathcal{E}) \). According to Proposition 4.6.2.13, \( X \) is left dualizable if and only if its image in \( _A\text{BMod}_1(\mathcal{E}) \simeq _A\text{BMod}_A(\mathcal{E}) \) is left dualizable. There is therefore no loss of generality in restricting our attention to case where \( B = 1 \). In this case, we can simplify the criterion of Proposition 4.6.2.1:

Proposition 4.6.2.18. Let \( \mathcal{C} \) be a monoidal \( \infty \)-category. Assume that \( \mathcal{C} \) admits geometric realizations of simplicial objects and that the tensor product \( \otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C} \) preserves geometric realizations of simplicial objects. Let \( A \in \mathcal{E}(\mathcal{C}) \), let \( X \in \text{LMod}_A(\mathcal{E}) \) and let \( Y \in \text{RMod}_A(\mathcal{E}) \). A morphism \( e : 1 \to Y \otimes_A X \) exhibits \( Y \) as a left dual of \( X \) if and only if the following condition is satisfied:

\[(*) \quad \text{For each } C \in \mathcal{C} \text{ and each } M \in \text{RMod}_A(\mathcal{E}), \text{ the composite map}
\]

\[
\text{Map}_{\text{RMod}_A(\mathcal{E})}(C \otimes Y, M) \to \text{Map}_\mathcal{C}(C \otimes Y \otimes_A X, M \otimes_A X) \xrightarrow{\circ e} \text{Map}_\mathcal{C}(C, M \otimes_A X)
\]

is a homotopy equivalence.
4.6. DUALITY

Proof. Let $\mathcal{M}$ be an $\infty$-category right-tensored over $\mathcal{C}$ such that $\mathcal{M}$ admits geometric realizations and the action map $M \times \mathcal{C} \to \mathcal{M}$ preserves geometric realizations. Let $F : \mathcal{M} \to \text{RMod}_A(M)$ be given by $M \mapsto N \otimes Y$. and let $G : \text{RMod}_A(M) \to \mathcal{M}$ be given by tensor product with $X$. Then $c$ induces a natural transformation $u : \text{id} \to G \circ F$. According to Proposition 4.6.2.1, it will suffice to show that $u$ is the unit of an adjunction between $F$ and $G$. In view of Remark 4.6.2.2, it suffices to prove this in the special cases $\mathcal{M} = \mathcal{C}$ and $\mathcal{M} = \text{LMod}_A(C)$. When $\mathcal{M} = \mathcal{C}$, this is a reformulation of $(*)$. When $\mathcal{M} = \text{LMod}_A(C)$, it is equivalent to the following variant of $(*)$:

\begin{equation}
(*)' \text{ For each } C \in \text{LMod}_A(C) \text{ and each } M \in \mathcal{A} \text{BMod}_A(C), \text{the composite map }
\theta_C : \text{Map}_{\mathcal{A} \text{BMod}_A(C)}(C \otimes Y, M) \to \text{Map}_{\text{LMod}_A(C)}(C \otimes Y \otimes_A X, M \otimes_A X) \xrightarrow{e} \text{Map}_{\text{LMod}_A(C)}(C, M \otimes_A X)
\end{equation}

is a homotopy equivalence.

We complete the proof by showing that $(*) \Rightarrow (*')$. Fix the bimodule $M \in \mathcal{A} \text{BMod}_A(C)$, and let $\mathcal{X} \subseteq \text{LMod}_A(C)$ be the full subcategory of $\text{LMod}_A(C)$ spanned by those objects $C$ for which $\theta_C$ is a homotopy equivalence. We wish to prove that $\mathcal{X} = \text{LMod}_A(C)$. Since $\mathcal{X}$ is closed under geometric realizations in $\text{LMod}_A(C)$, it suffices to show that $\mathcal{X}$ contains every free left module $C = A \otimes C_0$. In this case, we have a commutative diagram

\[
\begin{array}{c}
\text{Map}_{\mathcal{A} \text{BMod}_A(C)}(C \otimes Y, M) \xrightarrow{\theta_C} \text{Map}_{\text{LMod}_A(C)}(C, M \otimes_A X) \\
\downarrow \\
\text{Map}_{\text{RMMod}_A(C)}(C_0 \otimes Y, M) \xrightarrow{\theta'} \text{Map}_{\mathcal{C}}(C_0, M \otimes_A X),
\end{array}
\]

where the vertical maps are homotopy equivalences and $\theta'$ is a homotopy equivalence by $(*)$. \hfill \Box

We close this section with a few remarks about duality for modules over commutative algebras.

**Proposition 4.6.2.19.** Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category which admits geometric realizations of simplicial objects, and assume that the tensor product functor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves geometric realizations of simplicial objects. Let $A \in \text{CAlg}(\mathcal{C})$ be a commutative algebra object of $\mathcal{C}$, so that $\text{Mod}_A(\mathcal{C})$ inherits the structure of a symmetric monoidal $\infty$-category (see §4.5.2). Let $M$ be an object of $\text{Mod}_A(\mathcal{C})$, and let $\overline{M}$ denote the image of $M$ under the equivalence $\text{Mod}_A(\mathcal{C}) \to \text{LMod}_A(\mathcal{C}) \simeq \mathcal{A} \text{BMod}_1(\mathcal{C})$ of Corollary 4.5.1.6. Then:

(a) Suppose that $M$ is dualizable as an object of the symmetric monoidal $\infty$-category $\text{Mod}_A(\mathcal{C})$, so that there exists a duality datum $e : M \otimes_A N \to A$ in $\text{Mod}_A(\mathcal{C})$. Let $\overline{N}$ denote the image of $N$ in $\text{RMod}_A(\mathcal{C})$. Then the induced morphism

\[
\overline{M} \otimes \overline{N} \to M \otimes_A N \xrightarrow{e} A
\]

in $\mathcal{A} \text{BMod}_A(\mathcal{C})$ is a duality datum: that is, we can identify $\overline{N}$ with the left dual of $\overline{M}$, in the sense of Definition 4.6.2.3).

(b) Suppose that $\overline{M}$ is a left dualizable object of $\text{LMod}_A(\mathcal{C}) \simeq \mathcal{A} \text{BMod}_1(\mathcal{C})$. Then $M$ is a dualizable object of $\text{Mod}_A(\mathcal{C})$.

**Remark 4.6.2.20.** In the situation of Proposition 4.6.2.19, suppose that $\overline{M}$ is left dualizable, so that there exists a map $\overline{e} : \overline{M} \otimes \overline{N} \to A$ in $\mathcal{A} \text{BMod}_A(\mathcal{C})$ which exhibits $\overline{N}$ as a left dual of $\overline{M}$. It follows from the second assertion of Proposition 4.6.2.19 that $M$ is a dualizable object of $\text{Mod}_A(\mathcal{C})$. Choose a duality datum $e : M \otimes_A M \to A$ in $\text{Mod}_A(\mathcal{C})$. Let $\overline{M}$ denote the image of $\overline{M}$ in $\text{RMod}_A(\mathcal{C})$, so that $e$ induces a map $e' : \overline{M} \otimes \overline{M} \to A$ in $\mathcal{A} \text{BMod}_A(\mathcal{C})$. Then $e'$ classifies a morphism $\theta : \overline{M} \to \overline{N}$ in $\text{RMod}_A(\mathcal{C})$. The first
Construction 4.6.3.1. Let \( M \otimes \mathbb{N} \simeq \mathbb{M} \otimes \mathbb{M} \hookrightarrow A \).

We may summarize the situation more informally by saying that any duality datum \( \theta \) induces an involution on \( \text{BMod}(\mathcal{C}) \), which we will denote by \( \theta \). Our goal in this section is to give two different constructions for \( \theta \), which we will also denote by \( \theta \). We will refer to this involution as the reversal involution. For every symmetric monoidal \( \infty \)-category \( \mathcal{C} \), we denote the map of operads which is given on objects by the formula:

\[
\text{rev}(a_{-}) = a_{+} \quad \text{rev}(m) = m \quad \text{rev}(a_{+}) = a_{-},
\]

and which is given on morphisms by replacing every linear ordering by its opposite. Then \( \text{rev} \) induces an involution on the \( \infty \)-operad \( \mathbb{R} \mathbb{M}^\circ \), which we will also denote by \( \text{rev} \). We will refer to this involution as the reversal involution. For every symmetric monoidal \( \infty \)-category \( \mathcal{C} \), precomposition with the reversal involution induces an involution on \( \text{BMod}(\mathcal{C}) \), which we will denote by \( M \mapsto M^{\text{rev}} \). Note that for \( M \in \text{A BMod}_{B}(\mathcal{C}) \), we have \( M^{\text{rev}} \in \text{B rev} \text{BMod}_{A^{\text{rev}}}(\mathcal{C}) \).
Remark 4.6.3.2. The reversal involution of $\mathcal{B}M^\circ$ carries the full subcategory $\mathcal{L}M^\circ \subseteq \mathcal{B}M^\circ$ into $\mathcal{R}M^\circ \subseteq \mathcal{B}M^\circ$, and vice-versa. Consequently, if $\mathcal{C}$ is a symmetric monoidal $\infty$-category, composition with rev determines an isomorphism of simplicial sets $\text{LMod}(\mathcal{C}) \simeq \text{RMod}(\mathcal{C})$, which carries $\text{LMod}_A(\mathcal{C})$ into $\text{RMod}_A^{\text{rev}}(\mathcal{C})$.

Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category, and let $M \in _A\text{BMod}_C(\mathcal{C})$. Construction 4.6.3.1 allows us to trade the left action of $A$ on $M$ for a right action of $A^{\text{rev}}$ on $M$, provided that we simultaneously trade the right action of $C$ on $M$ for a left action of $C^{\text{rev}}$ on $M$. However, for our applications in §4.6.4, we will need a variant which allows us to trade our left action of $A$ on $M$ for a right action of $A^{\text{rev}}$, while retaining our given right action of $C$. More generally, for any triple of algebra objects $A, B, C \in \text{Alg}(\mathcal{C})$, there is a canonical equivalence of $\infty$-categories

$$\sigma_{A,B,C} : A \otimes_{B} \text{BMod}_C(\mathcal{C}) \simeq _B\text{BMod}_{A^{\text{rev}} \otimes C}(\mathcal{C}).$$

For convenience, we will make the following auxiliary assumption on $\mathcal{C}$:

(*) The $\infty$-category $\mathcal{C}$ admits geometric realizations of simplicial objects, and the tensor product functor $\otimes : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$ preserves geometric realizations of simplicial objects.

As we saw in §4.4.2, assumption (*)& guarantees the existence of a well-behaved relative tensor product of bimodules, which we will use to construct the equivalence $\sigma_{A,B,C}$. However, assumption (*) is not really essential: we can always pass to a situation where (*) is satisfied by enlarging the symmetric monoidal $\infty$-category $\mathcal{C}$ (for example, we can replace $\mathcal{C}$ by the $\infty$-category of presheaf $\mathcal{P}(\mathcal{C})$: see Corollary 4.8.1.12).

Notation 4.6.3.3. Using Construction 3.2.4.1, we can regard the $\infty$-category $\text{BMod}(\mathcal{C})$ of bimodule objects of $\mathcal{C}$ as a symmetric monoidal structure on $\mathcal{C}$. To avoid confusion, we will denote the tensor product on $\text{BMod}(\mathcal{C})$ using the symbol $\boxtimes$, and refer to it as the external tensor product. Given a pair of bimodule objects

$$M \in _A\text{BMod}_B(\mathcal{C}) \quad M' \in _A\text{BMod}_{B'}(\mathcal{C}),$$

we regard $M \boxtimes M'$ as an object of $\mathcal{A} \otimes _A\text{BMod}_{B \otimes B'}(\mathcal{C})$.

Remark 4.6.3.4. The symmetric monoidal structure on $\mathcal{C}$ induces a symmetric monoidal structure on the $\infty$-category $\text{Alg}_{\text{Ten}}(\mathcal{C})$, which is compatible with the tensor product $\boxtimes$ on $\text{BMod}(\mathcal{C})$ introduced in Notation 4.6.3.3. Using Theorem 4.4.2.8 (and our assumption that the tensor product on $\mathcal{C}$ is compatible with geometric realizations of simplicial objects) we deduce that if $X, Y \in \text{Alg}_{\text{Ten}}(\mathcal{C})$ are operadic left Kan extensions of their restrictions to $\text{Tens}^\circ \times _A \{0\}$, then the tensor product $X \otimes Y$ has the same property. It follows that the external tensor product $\boxtimes$ of Notation 4.6.3.3 is compatible with the relative tensor product of bimodules introduced in §4.4.2. That is, for every quadruple of bimodules

$$M \in _A\text{BMod}_B(\mathcal{C}) \quad N \in _B\text{BMod}_C(\mathcal{C})$$

$$M' \in _A\text{BMod}_{B'}(\mathcal{C}) \quad N' \in _B\text{BMod}_{C'}(\mathcal{C}),$$

we have a canonical equivalence

$$(M \otimes_B N) \boxtimes (M' \otimes_{B'} N') \simeq (M \boxtimes M') \otimes_{B \otimes B'} (N \boxtimes N')$$

in the $\infty$-category $\mathcal{A} \otimes _A\text{BMod}_{C \otimes C'}(\mathcal{C})$.

Remark 4.6.3.5. Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category satisfying condition (*). Using Remark 4.6.3.4, we deduce that if $M \in _A\text{BMod}_B(\mathcal{C})$ and $M' \in _A\text{BMod}_{B'}(\mathcal{C})$ are left dualizable (right dualizable), then the external tensor product $M \boxtimes M'$ is also left dualizable (right dualizable). Moreover, a left dual (right dual) for $M \boxtimes M'$ is given by $M^* \boxtimes M'^*$, where $M^* \in _B\text{BMod}_{A}(\mathcal{C})$ and $M'^* \in _B\text{BMod}_{A'}(\mathcal{C})$ are left duals (right duals) for $M$ and $N$, respectively.
Remark 4.6.3.6. Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category. Then the reversal involution

$$\text{rev} : \text{BMod}(\mathcal{C}) \rightarrow \text{BMod}(\mathcal{C})$$

of Construction 4.6.3.1 is a symmetric monoidal functor. In particular, for every pair of objects $M \in \mathcal{A}\text{BMod}_{B}(\mathcal{C})$, $M' \in \mathcal{A}'\text{BMod}_{B'}(\mathcal{C})$ we have a canonical equivalence

$$(M \otimes M')^{\text{rev}} \simeq M^{\text{rev}} \otimes M'^{\text{rev}} \in B_{\text{rev}} \otimes B'_{\text{rev}}\text{BMod}_{A^{\text{rev}} \otimes A'^{\text{rev}}}(\mathcal{C}).$$

Let $A$ be an algebra object of a symmetric monoidal $\infty$-category $\mathcal{C}$. Then we can regard $A$ as equipped with commuting left and right actions of itself. Consequently, we should be able to view $A$ as either a left or right module over the tensor product $A^{\text{rev}} \otimes A$. We now describe an explicit construction of the relevant left and right module objects of $\mathcal{C}$.

Construction 4.6.3.7. We define a “fold map” $f : \mathcal{L}M^{\otimes} \rightarrow \mathcal{Ass}^{\otimes}$ as follows:

- Let $\langle (n), S \rangle$ be an object of $\mathcal{LM}^{\otimes}$. Then $f(\langle n \rangle, S) = \langle n + k \rangle$, where $k = n - |S|$.

- Let $\alpha : \langle (n), S \rangle \rightarrow \langle (n'), S' \rangle$ be a morphism in $\mathcal{LM}^{\otimes}$, given by a map of finite pointed sets $\langle n \rangle \rightarrow \langle n' \rangle$ together with a linear ordering on $\alpha^{-1}\{i\}$ for $1 \leq i \leq n'$. Write $\langle n \rangle^{\circ} - S = \{i_1 < i_2 < \cdots < i_k\}$ and $\langle n' \rangle^{\circ} - S' = \{i'_1 < i'_2 < \cdots < i'_k\}$. As a map of finite pointed sets, $f(\alpha) : \langle n + k \rangle \rightarrow \langle n' + k' \rangle$ is given by

$$\begin{align*}
\alpha(p) & \quad \text{if } p \leq n \\
\alpha(i) & \quad \text{if } p = n + i, \alpha(i) \in S' \cup \{\ast\} \\
n' + i'_j & \quad \text{if } p = n + i, \alpha(i) = i'_j.
\end{align*}$$

To complete the definition of $f(\alpha)$, we must supply a linear ordering $\preceq_{f(\alpha)}$ on $f(\alpha)^{-1}\{j\}$, for $1 \leq j \leq n' + k'$. Let $j_0 = \begin{cases} j & \text{if } j \leq n \\ j - n & \text{if } j > n \end{cases}$, so that $\alpha$ determines a linear ordering $\preceq_{\alpha}$ on $\alpha^{-1}\{j_0\}$. We now define $\preceq_{f(\alpha)}$ so that so that $i \preceq_{f(\alpha)} i'$ if either $i, i' \leq n$ and $i \preceq_{\alpha} i'$, $i \leq n$ and $i' > n$, or $i, i' > n$ and $i' - n \preceq_{\alpha} i - n$.

Then $f$ induces a map of $\infty$-categories $\mathcal{LM}^{\otimes} \rightarrow \mathcal{Ass}^{\otimes}$, which we will also denote by $f$. Let $p : \mathcal{LM}^{\otimes} \rightarrow \mathcal{N}(\mathcal{Fin}_{+})$ and $p' : \mathcal{Ass}^{\otimes} \rightarrow \mathcal{N}(\mathcal{Fin}_{+})$ be the forgetful functors. There is a natural transformation $\iota : p' \circ f \rightarrow p$, which carries each object $\langle (n), S \rangle$ to the map of finite pointed sets $\iota(\langle (n), S \rangle) : \langle n + k \rangle \rightarrow \langle n \rangle$ given by

$$\iota(\langle (n), S \rangle)(j) = \begin{cases} j & \text{if } 1 \leq j \leq n \\ i_{j - n} & \text{if } j > n, \langle n \rangle^{\circ} - S = \{i_1 < \cdots < i_k\}. \end{cases}$$

Let $q : \mathcal{E}^{\otimes} \rightarrow \mathcal{N}(\mathcal{Fin}_{+})$ be a symmetric monoidal $\infty$-category. For every algebra object $A \in \mathcal{Alg}(\mathcal{C})$, we can lift $\iota$ to a $q$-coCartesian natural transformation $A \circ f \rightarrow A^{\circ}$ in the $\infty$-category $\mathcal{Fun}(\mathcal{LM}^{\otimes}, \mathcal{C}^{\otimes})$. Then $A^{\circ}$ is an object of $\mathcal{Alg}_{\mathcal{LM}}(\mathcal{C}) = \mathcal{LM}(\mathcal{C})$, whose image under the forgetful functor $\mathcal{LM}(\mathcal{C}) \rightarrow \mathcal{Alg}(\mathcal{C})$ is the tensor product $A \otimes A^{\text{rev}}$, and whose image under the forgetful functor $\mathcal{LMod}(\mathcal{C}) \rightarrow \mathcal{C}$ is given by $A$. We will refer to $A^{\circ}$ as the evaluation module of $A$.

We let $A^{\circ}$ denote the image of $A$ under the reversal isomorphism $\mathcal{LMod}(\mathcal{C}) \simeq \mathcal{RMod}(\mathcal{C})$, so that $A^{\circ}$ is a right module over $A^{\text{rev}} \otimes A$, whose image in $\mathcal{C}$ can be identified with $A$. We will refer to $A^{\circ}$ as the coevaluation module of $A$.

Remark 4.6.3.8. Let $A$ be an algebra object of a symmetric monoidal $\infty$-category $\mathcal{C}$. The construction of the evaluation and coevaluation modules $A^{\circ}$ and $A^{\circ}$ is symmetric with respect to the interchange of $A$ with its opposite algebra $A^{\text{rev}}$. That is, we can identify $\langle A^{\text{rev}} \rangle^{\circ}$ with the image of $A^{\circ}$ under the equivalence $\mathcal{LMod}_{A^{\text{rev}}}(\mathcal{C}) \simeq \mathcal{LMod}_{A^{\text{rev}} \otimes A}(\mathcal{C})$, and $\langle A^{\text{rev}} \rangle^{\circ}$ with the image of $A^{\circ}$ under the equivalence $\mathcal{RMod}_{A^{\text{rev}}}(\mathcal{C}) \simeq \mathcal{RMod}_{A^{\text{rev}} \otimes A}(\mathcal{C})$. 
If $A$ is an algebra object of a symmetric monoidal $\infty$-category $\mathcal{C}$, then we can use the evaluation and coevaluation modules $A^e$ and $A^c$ to “mediate” between left action actions of $A$ and right actions of $A^{rev}$.

**Construction 4.6.3.9.** Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category which satisfies condition $(\ast)$. Let $A$, $B$, and $C$ be algebra object of $\mathcal{C}$, and let let $A^e$ and $A^c$ denote the evaluation and coevaluation modules associated to $A$. Let $1$ denote the unit object of $\mathcal{C}$, regarded as an initial object of $\text{Alg}(\mathcal{C})$. Using Corollary 4.3.2.8, we can identify $A^e$ and $A^c$ with objects of $A \otimes A^{rev} \text{BMod}_1(\mathcal{C})$ and $1 \text{BMod}_A(\mathcal{C})$, respectively, so that we obtain bimodules

$$A^e \otimes B \in _B \text{BMod}_{A^{rev} \otimes A \otimes B}(\mathcal{C}) \quad A^c \otimes C \in _A \text{BMod}_{A^{rev} \otimes C \otimes B}(\mathcal{C}).$$

We define functors

$$\sigma_{A,B,C} : _A \otimes B \text{BMod}_C(\mathcal{C}) \to _B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C}) \quad \tau_{A,B,C} : _B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C}) \to _A \otimes B \text{BMod}_C(\mathcal{C})$$

by the formulas

$$\sigma_{A,B,C}(M) = (A^e \otimes B) \otimes_{A^{rev} \otimes A \otimes B} (A^{rev} \otimes M)$$

$$\tau_{A,B,C}(N) = (A \otimes N) \otimes_{A \otimes A^{rev} \otimes C} (A^c \otimes C).$$

**Remark 4.6.3.10.** Let $A$, $B$, and $C$ be as in Construction 4.6.3.9, and let $M \in _A \otimes B \text{BMod}_C(\mathcal{C})$. Note that the image of $A^{rev} \otimes M$ under the forgetful functor $A^{rev} \otimes _A \otimes B \text{BMod}_A(\mathcal{C}) \to A^{rev} \otimes _A \otimes B \text{BMod}_C(\mathcal{C})$ is given by

$$(A^e \otimes B) \otimes_{A^{rev} \otimes A \otimes B} (A^{rev} \otimes M) \simeq (A \otimes B) \otimes_{A \otimes B} M \simeq M.$$ 

In other words, the diagram

$$\begin{array}{ccc}
_A \otimes B \text{BMod}_C(\mathcal{C}) & \xrightarrow{\sigma_{A,B,C}} & _B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C}) \\
\downarrow & & \downarrow \\
_B \text{BMod}_C(\mathcal{C}) & \xrightarrow{\tau_{A,B,C}} & _A \otimes B \text{BMod}_C(\mathcal{C})
\end{array}$$

commutes up to canonical homotopy.

**Proposition 4.6.3.11.** Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category satisfying condition $(\ast)$, and let $A, B, C \in \text{Alg}(\mathcal{C})$. Then the functors

$$\sigma_{A,B,C} : _A \otimes B \text{BMod}_C(\mathcal{C}) \to _B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C}) \quad \tau_{A,B,C} : _B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C}) \to _A \otimes B \text{BMod}_C(\mathcal{C})$$

introduced in Construction 4.6.3.9 are mutually inverse equivalences of $\infty$-categories.

In the situation of Proposition 4.6.3.11, choose an object $M \in _A \otimes B \text{BMod}_C(\mathcal{C})$. Repeatedly using Remark 4.6.3.4 and the associativity and unitality of the relative tensor product of bimodules, we obtain functorial equivalences

$$\tau_{A,B,C} \sigma_{A,B,C}(M) = \tau_{A,B,C}((A^e \otimes B) \otimes_{A^{rev} \otimes A \otimes B} (A^{rev} \otimes M))$$

$$= (A \otimes ((A^e \otimes B) \otimes_{A^{rev} \otimes A \otimes B} (A^{rev} \otimes M))) \otimes_{A \otimes A^{rev} \otimes C} (A^c \otimes C)$$

$$\simeq (A \otimes A^c \otimes B) \otimes_{A \otimes A^{rev} \otimes A \otimes B} (A \otimes A^{rev} \otimes M) \otimes_{A \otimes A^{rev} \otimes C} (A^c \otimes C)$$

$$\simeq (A \otimes A^c \otimes B) \otimes_{A \otimes A^{rev} \otimes A \otimes B} (A^c \otimes M)$$

$$\simeq ((A \otimes A^c) \otimes_{A \otimes A^{rev} \otimes A} (A^c \otimes A)) \otimes B) \otimes_{A \otimes B} M.$$

For $N \in _B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C})$, a similar calculation gives

$$\sigma_{A,B,C} \tau_{A,B,C}(N) \simeq N \otimes_{A^{rev} \otimes C} (((A^e \otimes A^{rev}) \otimes_{A \otimes A^{rev}} (A^{rev} \otimes A^c)) \otimes C).$$

Consequently, Proposition 4.6.3.11 can be reduced to the following special case:
Proposition 4.6.3.12. Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category satisfying condition $(\ast)$, and let $A$ be an algebra object of $\mathcal{C}$. Then we have equivalences

$$(A \otimes A^c) \otimes_{A \otimes A^{rev} \otimes A} (A^c \otimes A) \simeq A$$

$$(A^c \otimes A^{rev}) \otimes_{A^{rev} \otimes A \otimes A^{rev}} (A^{rev} \otimes A^c) \simeq A^{rev}$$

in the $\infty$-categories $\mathcal{A}BMod_A(\mathcal{C})$ and $A^{rev}BMod_{A^{rev}}(\mathcal{C})$, respectively. Moreover, these equivalences can be chosen to depend functorially on $A$.

The proof of Proposition 4.6.3.12 is rather notationally intensive; we will defer it until the end of this section.

Remark 4.6.3.13. The equivalences $\sigma_{A,B,C}$ and $\tau_{A,B,C}$ of Construction 4.6.3.9 depend functorially on the triple $A$, $B$, and $C$. More precisely, suppose that we are given maps of algebra objects $A \to A'$, $B \to B'$, and $C \to C'$, so that we have associated forgetful functors

$$\phi : A \otimes B \mathcal{B}Mod_C(\mathcal{C}) \to A' \otimes B \mathcal{B}Mod_C(\mathcal{C})$$

$$\psi : B' \mathcal{B}Mod_{A^{rev} \otimes C}(\mathcal{C}) \to B \mathcal{B}Mod_{A^{rev} \otimes C}(\mathcal{C}).$$

We have evident maps of bimodule objects $A^c \to A'^c$, $A^e \to A'^e$, which determine natural transformations

$$\alpha : \sigma_{A,B,C} \circ \phi \to \psi \circ \sigma_{A',B',C'}$$

$$\beta : \tau_{A,B,C} \circ \phi \to \phi \circ \tau_{A',B',C'}.$$ 

We claim that $\alpha$ and $\beta$ are equivalences. To prove this, we note that the functoriality assertion of Proposition 4.6.3.12 guarantees that the composite transformation

$$\tau_{A,B,C} \circ \sigma_{A,B,C} \circ \phi \circ \tau_{A',B',C'} \circ \alpha \circ \tau_{A',B',C'}$$

is homotopic to an equivalence. This guarantees that $\alpha$ admits a left homotopy inverse and that $\beta$ admits a right homotopy inverse. A similar argument shows that $\alpha$ admits a right homotopy inverse and $\beta$ a left homotopy inverse.

Remark 4.6.3.14. Let $A$ and $A'$ be algebra objects of $\mathcal{C}$. Then the evaluation and coevaluation modules for the tensor product $A \otimes A'$ are given by

$$(A \otimes A')^c \simeq A^c \otimes A'^c$$

$$(A \otimes A')^e \simeq A^e \otimes A'^e.$$ 

From this, we deduce that for any pair of algebra objects $B, C \in \text{Alg}(\mathcal{C})$, the functor

$$\sigma_{A \otimes A',B,C} : A \otimes A' \otimes B \mathcal{B}Mod_C(\mathcal{C}) \to B \mathcal{B}Mod_{A^{rev} \otimes A'^{rev} \otimes C}(\mathcal{C})$$

is equivalent to the composition

$$A \otimes A' \otimes B \mathcal{B}Mod_C(\mathcal{C}) \xrightarrow{\sigma_{A,\otimes A',B,C}} A' \otimes B \mathcal{B}Mod_{A^{rev} \otimes C}(\mathcal{C}) \xrightarrow{\sigma_{A',B,C^{rev}} \otimes C} B \mathcal{B}Mod_{A^{rev} \otimes A'^{rev} \otimes C}(\mathcal{C}) \simeq B \mathcal{B}Mod_{A^{rev} \otimes A'^{rev} \otimes C}(\mathcal{C}).$$

The mutually inverse equivalences given by Construction 4.6.3.9 are closely related to the reversal involution on $\mathcal{B}Mod(\mathcal{C})$ introduced in Construction 4.6.3.1. More precisely, we have the following result:

Proposition 4.6.3.15. Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category satisfying condition $(\ast)$, and let $A$ and $B$ be algebra objects of $\mathcal{C}$. Then the diagram

$$\xymatrix{ A \otimes B \mathcal{B}Mod_1(\mathcal{C}) \ar[r]^-{\sim} \ar[d]^{\ sigma_{A,B,1}} & B \otimes A \mathcal{B}Mod_1(\mathcal{C}) \ar[d]^{\ sigma_{B,A,1}} \\
B \mathcal{B}Mod_{A^{rev}}(\mathcal{C}) \ar[r]^-{\ rev} & \mathcal{A} \mathcal{B}Mod_{B^{rev}}(\mathcal{C}) }$$

commutes up canonical homotopy (which may be chosen to depend functorially on $A$ and $B$).
Remark 4.6.3.16. Let \( \mathcal{C} \) be a symmetric monoidal \( \infty \)-category satisfying condition (\( \ast \)). The reversal involution of Construction 4.6.3.1 extends naturally to an involution of the generalized \( \infty \)-operad \( \text{Tens}^\otimes \mathcal{C} \) of Notation 4.4.2.1. It follows that for every pair of bimodules \( M \in \text{BMod}_B(\mathcal{C}) \) and \( N \in \text{BMod}_C(\mathcal{C}) \), we have a canonical equivalence

\[
(M \otimes_B N)^{\text{rev}} \simeq N^{\text{rev}} \otimes_B M^{\text{rev}}.
\]

Remark 4.6.3.17. Let \( A, B, \) and \( C \) be algebra objects of \( \mathcal{C} \). Combining Remarks 4.6.3.6 and 4.6.3.16, we deduce that the diagram

\[
\begin{array}{ccc}
A \otimes_B \text{BMod}_C(\mathcal{C}) & \xrightarrow{\sigma_{A,B,C}} & \text{BMod}_{A^{\text{rev}} \otimes C}(\mathcal{C}) \\
\downarrow \text{rev} && \downarrow \text{rev} \\
C^{\text{rev}} \text{BMod}_{A^{\text{rev}} \otimes B^{\text{rev}}}(\mathcal{C}) & \xrightarrow{T_{A^{\text{rev}},B^{\text{rev}}}^{C^{\text{rev}}}} & A^{\otimes \text{rev}} \otimes \text{BMod}_{B^{\text{rev}}}(\mathcal{C})
\end{array}
\]

commutes up to canonical homotopy.

Let \( A, B \in \text{Alg}(\mathcal{C}) \). Using Remark 4.6.3.17, we see that the commutativity of the diagram appearing in Proposition 4.6.3.15 is equivalent to the commutativity of the diagram

\[
\begin{array}{ccc}
A \otimes_B \text{BMod}_1(\mathcal{C}) & \xrightarrow{\sim} & B \otimes_A \text{BMod}_1(\mathcal{C}) \\
\downarrow \text{rev} && \downarrow \sigma_{B,A,1} \\
\text{BMod}_{A^{\text{rev}} \otimes B^{\text{rev}}}(\mathcal{C}) & \xrightarrow{T_{A^{\text{rev}},B^{\text{rev}}}^{C^{\text{rev}}}} & A^{\otimes \text{rev}} \otimes \text{BMod}_{B^{\text{rev}}}(\mathcal{C})
\end{array}
\]

Using Proposition 4.6.3.11, we see that Proposition 4.6.3.15 is equivalent to the assertion that the equivalence \( \text{rev} : A \otimes_B \text{BMod}_1(\mathcal{C}) \to B \otimes_A \text{BMod}_1(\mathcal{C}) \) is homotopic to the composition

\[
A \otimes_B \text{BMod}_1(\mathcal{C}) \simeq B \otimes_A \text{BMod}_1(\mathcal{C}) \xrightarrow{\sigma_{B,A,1}} \text{BMod}_{B^{\text{rev}}}(\mathcal{C}) \xrightarrow{T_{A^{\text{rev}},B^{\text{rev}}}^{C^{\text{rev}}}} A^{\otimes \text{rev}} \otimes \text{BMod}_{B^{\text{rev}}}(\mathcal{C})
\]

(via a homotopy which can be chosen to depend functorially on \( A \) and \( B \)). Using Remark 4.6.3.14, we can identify this composition with the functor \( \sigma_{A \otimes B,1,1} \). Consequently, Proposition 4.6.3.15 is equivalent to the following apparently weaker statement:

**Proposition 4.6.3.18.** Let \( A \) be an algebra object of \( \mathcal{C} \), and let \( M \) be a left \( A \)-module object of \( \mathcal{C} \). Then there is an equivalence \( \sigma_{A,1,1}(M) \simeq M^{\text{rev}} \) in \( \text{BMod}_{A^{\text{rev}}}(\mathcal{C}) \), which can be chosen to depend functorially on \( A \) and \( M \).

**Proof.** We will prove Proposition 4.6.3.18 by constructing a map

\[
\theta : A^c \otimes A^{\text{rev}} \otimes A (A^{\text{rev}} \boxtimes M) \to M^{\text{rev}},
\]

and then proving that this map is an equivalence. Our construction will be manifestly functorial in the pair \((A,M)\) (alternatively, one can deduce the functoriality by replacing \( \mathcal{C} \) by \( \text{Fun}(K, \mathcal{C}) \), where \( K = \text{LMod}(\mathcal{C}) \)).

In what follows, it will be convenient to replace \( \text{Fin}_n \) by the larger (but equivalent) category consisting of all finite pointed sets, and to make corresponding enlargements of the \( \infty \)-categories \( \text{Tens}^\otimes \mathcal{C} \) and \( \mathcal{L}^{\text{Mod}} \). We will therefore identify objects of \( \text{Tens}^\otimes \mathcal{C} \) with pairs \((S_*, [k], c_-, c_+)\), where \( S_* \) is a finite pointed set, \( k \in \{0, 1, 2\} \), and \( c_-, c_+ : S \to [k] \) are maps satisfying \( c_-(i) \leq c_+(i) \leq c_-(i) + 1 \), and objects of \( \mathcal{L}^{\text{Mod}} \) with pairs \((J_*, J_0)\), where \( J_* \) is a finite pointed set and \( J_0 \) is a subset of \( J \).

We now define a functor \( f : \text{Tens}^\otimes \to \mathcal{L}^{\text{Mod}} \) via the following explicit (but unfortunately rather complicated) procedure:

(a) Let \( X \) be an object of \( \text{Tens}^\otimes \times_{\Delta^1} \{1\} \), corresponding to a finite pointed set \( T_* \) equipped with a pair of maps \( c_-, c_+ : T \to [1] \). Write \( T \) as a disjoint union of subsets

\[
T_0 = \{t \in T : c_-(t) = c_+(t) = 0\} \quad T_1 = \{t \in T : c_-(t) = c_+(t) = 1\}
\]
We then define $f(X)$ to be the pair $(J, T_{01} \times \{1\})$, where

$$J = (T_1 \times \{0\}) \cup (T_{01} \times \{1\}) \subseteq T \times [1].$$

(b) Let $\alpha : (T_*, c_-, c_+) \rightarrow (T'_*, c'_-, c'_+)$ be a morphism in $\text{Tens}^\otimes \times \Delta \{1\}$, given by a map of finite pointed sets $T_* \rightarrow T'_*$ (which we will also denote by $\alpha$) together with a linear ordering $\preceq_{\alpha, t}$ of each inverse image $\alpha^{-1}\{t'\}$. For $\xi \in \{0, 01, 1\}$, define $T_\xi$ and $J$ as in (a), and define $T'_{\xi}$ and $J'$ similarly. We define a map of pointed sets $f(\alpha) : J_\ast \rightarrow J'_\ast$ by the following formula:

$$f(\alpha)(t, 0) = \begin{cases} 
(\alpha(t), 0) & \text{if } \alpha(t) \in T'_1 \\
(\alpha(t), 1) & \text{if } \alpha(t) \in T'_{01} \\
* & \text{if } \alpha(t) = *
\end{cases}$$

$$f(\alpha)(t, 1) = \begin{cases} 
(\alpha(t), 1) & \text{if } \alpha(t) \in T'_1 \\
* & \text{if } \alpha(t) = *.
\end{cases}$$

For each $(t', j) \in J'$, we define a linear ordering $\preceq_{f(\alpha)(t', j)}$ on $f(\alpha)^{-1}\{j'\}$ so that $(t_0, i_0) \preceq_{f(\alpha), (t', j)} (t_1, i_1)$ if and only if either $i_0 < i_1$, or $i_0 = i_1$ and $t_1 \preceq_{\alpha, t} t_0$.

(c) Let $X$ be an object of $\text{Tens}^\otimes \times \Delta \{0\}$, given by a finite pointed set $S_*$ equipped with a pair of maps $c_-, c_+ : S \rightarrow [2]$. Write $S$ as a disjoint union of subsets

$$S_0 = \{s \in S : c_-(s) = c_+(s) = 0\} \quad S_1 = \{s \in S : c_-(s) = c_+(s) = 1\}$$

$$S_{01} = \{s \in S : c_-(s) = 0, c_+(s) = 1\} \quad S_{12} = \{s \in S : c_-(s) = 1, c_+(s) = 2\}$$

We then define $f(X) = (I_\ast, S_{12} \times \{5\})$, where

$$I = (S_2 \times \{0\}) \cup (S_{12} \times \{1\}) \cup (S_1 \times \{2\}) \cup (S_{01} \times \{3\}) \cup (S_{1} \times \{4\}) \cup (S_{12} \times \{5\}) \subseteq S \times [5]$$

(d) Let $\alpha : (S_*, c_-, c_+) \rightarrow (S'_*, c'_-, c'_+)$ be a morphism in $\text{Tens}^\otimes \times \Delta \{0\}$, given by a map of finite pointed sets $S_* \rightarrow S'_*$ and a linear ordering $\preceq_{\alpha, s'}$ on each inverse image $\alpha^{-1}\{s'\}$ for $s' \in S'$. For $\xi \in \{0, 1, 2, 01, 12\}$, $S_\xi$ and $I$ as in (a), and define $S'_{\xi}$ and $I'$ similarly. As a map of pointed finite sets, $f(\alpha) : I_\ast \rightarrow I'_\ast$ is given as follows:

$$f(\alpha)(s, 0) = \begin{cases} 
(\alpha(s), 0) & \text{if } \alpha(s) \in S'_2 \\
(\alpha(s), 1) & \text{if } \alpha(s) \in S'_{01} \\
* & \text{if } \alpha(s) = *
\end{cases}$$

$$f(\alpha)(s, 1) = \begin{cases} 
(\alpha(s), 0) & \text{if } \alpha(s) \in S'_2 \\
* & \text{if } \alpha(s) = *
\end{cases}$$

$$f(\alpha)(s, 2) = \begin{cases} 
(\alpha(s), 1) & \text{if } \alpha(s) \in S'_1 \\
(\alpha(s), 2) & \text{if } \alpha(s) \in S'_{01} \\
(\alpha(s), 3) & \text{if } \alpha(s) \in S'_1 \\
* & \text{if } \alpha(s) = *
\end{cases}$$

$$f(\alpha)(s, 3) = \begin{cases} 
(\alpha(s), 3) & \text{if } \alpha(s) \in S'_{01} \\
* & \text{if } \alpha(s) = *.
\end{cases}$$
4.6. **DUALITY**

We will complete the proof by showing that this map is an equivalence: that is, that \( N \) encodes the pair of bimodules \( I, \) where \( \iota \) is Kan extension of the restriction \( N \) and that the restriction of \( J \) is defined as in \( (s_1, i_1) \) if and only if either \( i_0 < i_1 \) or one of the following conditions holds:

- We have \( i_0 = i_1 \in \{1,3,5\} \) (in which case we automatically have \( s_0 = s_1 \)).
- We have \( i_0 = i_1 \in \{0,2\} \) and \( s_1 \preceq_{s,s'} s_0 \).
- We have \( i_0 = i_1 = 4 \) and \( s_0 \preceq_{s,s'} s_1 \).

\( \text{(c) Let } \alpha : X \to Y \text{ be a morphism in } \text{Tens}^\otimes \text{ from an object } X \in \text{Tens}^\otimes \times \Delta^1 \{0\} \text{ to } Y \in \text{Tens}^\otimes \times \Delta^1 \{1\}. \) Define \( I \) and \( S^\ell \) as in \( (c) \), and define \( J \) and \( T^\ell \) as in \( (a) \). We define a map of finite pointed sets \( f(\alpha) : I_* \to J_* \text{ as follows:} \)

\[
f(\alpha)(s,i) = \begin{cases} 
  (\alpha(s),0) & \text{if } \alpha(s) \in T_1 \\
  (\alpha(s),1) & \text{if } \alpha(s) \in T_{01} \\
  * & \text{if } \alpha(s) = *.
\end{cases}
\]

For \((t,i) \in J_\ast\), we define a linear ordering \( \preceq_{f(\alpha),t,i} \) on the inverse image \( f(\alpha)^{-1}\{(t,i)\} \) exactly as in step \( (d) \). Let \( p : \text{Tens}^\otimes \to N(\mathbb{F}) \) and \( p' : \mathcal{L} \mathbb{M}^\otimes \to N(\mathbb{F}) \) denote the forgetful functors. There is an evident natural transformation \( \iota : p' \circ f \to p \), given on objects of \((S_\ast,c_-,c_+) \in \text{Tens}^\otimes \times \Delta^1 \{0\}\) by the composition

\[
I_* \hookrightarrow (S \times [5])_* \to S_*
\]

(where \( I \) is defined as in \( (c) \)), and on objects \((T_\ast,c_-,c_+) \in \text{Tens}^\otimes \times \Delta^1 \{1\}\) by the composition

\[
J_* \hookrightarrow (T \times [1])_* \to T_*
\]

(where \( J \) is defined as in \( (a) \)).

Let \( q : \mathbb{C}^\otimes \to N(\mathbb{F}) \) exhibit \( \mathbb{C}^\otimes \) as a symmetric monoidal \( \infty \)-category. The pair \((A,M)\) determines a map of \( \infty \)-operads \( \phi : \mathcal{L} \mathbb{M}^\otimes \to \mathbb{C}^\otimes \). We can lift \( \iota \) to a \( q \)-coCartesian natural transformation \( \phi \circ f \to N \) between functors from \( \text{Tens}^\otimes \to \mathbb{C}^\otimes \). Unwinding the definitions, we see that the restriction of \( N \) to \( \text{Tens}^\otimes \times \Delta^1 \{0\} \) encodes the pair of bimodules

\[
A^\ast \in 1 \text{BMod}_{A^\text{rev} \otimes A}(\mathbb{C}) \quad A^\text{rev} \boxtimes M \in A^\text{rev} \otimes A \text{BMod}_{A^\text{rev}}(\mathbb{C}),
\]

and that the restriction of \( N \) to \( \text{Tens}^\otimes \times \Delta^1 \{1\} \) can be identified with \( M^\text{rev} \in 1 \text{BMod}_{A^\text{rev}}(\mathbb{C}) \). Consequently, \( N \) determines a map of bimodules

\[
\sigma_{A,1,1}(M) = A^\ast \boxtimes_{A^\text{rev} \otimes A} (A^\text{rev} \boxtimes M) \to M^\text{rev}.
\]

We will complete the proof by showing that this map is an equivalence: that is, that \( N \) is an operadic \( q \)-left Kan extension of the restriction \( N|\{\text{Tens}^\otimes \times \Delta^1 \{0\}\} \). Let \( U_+ : \mathbb{N}(\Delta_+)^\text{op} \to \text{Tens}^\otimes \) be defined as in Notation 4.4.2.4. According to Proposition 4.4.2.5, it will suffice to verify that the composition \( N \circ U_+ : \mathbb{N}(\Delta_+)^\text{op} \to \mathbb{C}^\otimes \) is an operadic \( q \)-colimit diagram.

Let \( u : \mathbb{N}(\Delta_+)^\text{op} \to N(\mathbb{F}) \) denote the constant map taking the value \((1) \in N(\mathbb{F}) \). There is unique natural transformation \( \gamma : q \circ N \circ U_+ \to u \) which carries each object of \( \mathbb{N}(\Delta_+)^\text{op} \) to an active morphism in
Proof of Proposition 4.6.3.12. We will construct an equivalence $N(\Fin_\ast) \rightarrow N(\Fin_\ast)$ lifting $\gamma$, so that $B$ is an augmented simplicial object of the $\infty$-category $\mathcal{C}$. Using Propositions 3.1.1.15 and 3.1.1.16, we are reduced to proving that $B$ is a colimit diagram in $\mathcal{C}$.

Let $J$ denote the subcategory of $\Delta$ whose objects have the form $[n]$ for $n > 0$ and whose morphisms are order-preserving maps $\alpha : [m] \rightarrow [n]$ satisfying $f(0) = 0$ and $f^{-1}\{m\} = \{n\}$. Let $\text{Cut} : N(\Delta)^{op} \rightarrow \text{Ass}^{\circ}$ be as in Construction 4.1.2.5, given on objects by $\text{Cut}([n]) = \{n\}$, and let $\text{Cut}_0 = \text{Cut} | N(\Delta)^{op}$. We observe that $\text{Cut}_0$ lifts to a map $\overline{\text{Cut}}_0 : N(\Delta)^{op} \rightarrow \mathcal{L}M^{\circ}$, given on objects by $\overline{\text{Cut}}_0([n]) = ([n], \{n\})$. The functor $\overline{\text{Cut}}_0$ carries each morphism in $J$ to an active morphism in $\mathcal{L}M^{\circ}$. Consequently, there is a natural transformation $\delta$ from $p' \circ \text{Cut}_0$ to the constant functor $N(\Delta)^{op} \rightarrow N(\Fin_\ast)$ taking the value $(1)$, uniquely determined by the requirement that $\delta$ carries each object of $N(\Delta)^{op}$ to an active morphism in $N(\Fin_\ast)$. Choose a $q$-coCartesian natural transformation $\phi \circ \text{Cut}_0 \rightarrow B'$ of functors from $N(\Delta)^{op}$ to $\mathcal{C}^{\circ}$, so that we can regard $B'$ as a functor from $N(\Delta)^{op}$ into $\mathcal{C}$, given on objects by the formula $B'(\{n\}) = A^\otimes n \otimes M$.

Unwinding the definitions, we see that the functor $B$ is equivalent to the composition $N(\Delta)^{op} \xrightarrow{\epsilon} N(\Delta)^{op} B' \xrightarrow{\epsilon} \mathcal{C}$, where $\epsilon$ is induced by the functor $\Delta \rightarrow J$ given by $I \mapsto [0] \ast I^{op} \ast I \ast [0]$. We are therefore reduced to proving that $B' \circ \epsilon$ is a colimit diagram. This is clear, since $\epsilon$ is a split augmented simplicial object of $N(\Delta)^{op}$.

We conclude this section with a proof of Proposition 4.6.3.12. We use the same basic strategy as in our proof of Proposition 4.6.3.18, though the details are somewhat more tedious.

Proof of Proposition 4.6.3.12. We will construct an equivalence

$$(A \boxtimes A^\circ \otimes_{A \boxtimes A} \boxtimes A^\circ A) \simeq A;$$

the existence of the other equivalence will then follow by symmetry. Our construction will depend functorially on $A$ (though we can also deduce the functoriality by replacing $\mathcal{C}$ by the functor category $\text{Fun}(K, \mathcal{C})$, where $K = \text{Alg}(\mathcal{C})$, and taking $A$ to be the “universal algebra object of $\text{Fun}(K, \mathcal{C})$).

As in the proof of Proposition 4.6.3.18, we abuse notation by identifying $\Fin_\ast$ with the larger (but equivalent) category of all pointed finite sets, and make corresponding enlargements of the $\infty$-categories $\text{Tens}^{\circ}$ and $\text{Ass}^{\circ}$. We now define a functor $f : \text{Tens}^{\circ} \rightarrow \text{Ass}^{\circ}$ as follows:

(a) When restricted to $\text{Tens}^{\circ} \times_{\Delta} \{1\} \simeq \mathcal{B}M^{\circ}$, $f$ agrees with the forgetful functor $\mathcal{B}M^{\circ} \rightarrow \text{Ass}^{\circ}$ of Remark 4.3.1.8.

(b) Let $X$ be an object of $\text{Tens}^{\circ} \times_{\Delta} \{0\}$, given by a finite pointed set $S_\ast$ equipped with a pair of maps $c_-, c_+ : S \rightarrow [2]$. Write $S$ as a disjoint union of subsets

$$S_0 = \{s \in S : c_-(s) = c_+(s) = 0\} \quad S_1 = \{s \in S : c_-(s) = c_+(s) = 1\} \quad S_2 = \{s \in S : c_-(s) = c_+(s) = 2\}$$

$$S_{01} = \{s \in S : 0 = c_-(s) < c_+(s) = 1\} \quad S_{12} = \{s \in S : 1 = c_-(s) < c_+(s) = 2\}$$

$$f(X) = I_\ast$$, where $I$ denotes the subset of $S \times [8]$ given by the union of the subsets $S_0 \times \{0\}$, $S_0 \times \{1\}$, $S_1 \times \{2\}$, $S_2 \times \{3\}$, $S_1 \times \{4\}$, $S_0 \times \{5\}$, $S_1 \times \{6\}$, $S_2 \times \{7\}$, and $S_0 \times \{8\}$.

(c) Let $\alpha : (S_\ast, c_-, c_+) \rightarrow (S'_\ast, c'_-, c'_+)$ be a morphism in $\text{Tens}^{\circ} \times_{\Delta} \{0\}$, given by a map of finite pointed sets $S_\ast \rightarrow S'_\ast$ (which we will also denote by $\alpha$) together with a linear ordering $\leq_{\alpha,s'}$ on each inverse image $\alpha^{-1}\{s\}'$. Let $I$ and $S_\xi$ (for $\xi \in \{0, 1, 2, 01, 12\}$) be defined as in (b), and define $I'$ and $S'_\xi$ similarly. We define a map of pointed finite sets $f(\alpha) : I_\ast \rightarrow I'_\ast$ as follows:

$$f(\alpha)(s, 0) = \begin{cases} (\alpha(s), 0) & \text{if } \alpha(s) \in S'_0 \\ (\alpha(s), 1) & \text{if } \alpha(s) \in S'_0 \\ * & \text{if } \alpha(s) = * \end{cases}$$
4.6. DUALITY

Let $s, s' \in S$ be a morphism in $\text{Tens}$. For each $(s', j) \in I'$, we define a linear ordering $\preceq_{f(\alpha),(s', j)}$ on the inverse image $f(\alpha)^{-1}\{s', j\}$ as follows: we have $(s_0, i_0) \preceq_{f(\alpha),(s', j)} (s_1, i_1)$ if and only if either $i_0 < i_1$, or one of the following conditions holds:

- We have $i_0 = i_1 \in \{1, 3, 5, 7\}$ (in which case we automatically have $s_0 = s_1$).
- We have $i_0 = i_1 \in \{0, 2, 6, 8\}$ and $s_0 \preceq_{s', s'} s_1$.
- We have $i_0 = i_1 = 4$ and $s_0 \preceq_{s', s'} s_0$.

(d) Let $\alpha$ be a morphism in $\text{Tens}^\circ$ from an object $(S_*, c_-, c_+)$ to an object $(S'_*, c'_-, c'_+)$ in $\text{Tens}^\circ \times \Delta^\circ \{1\}$, given by a map of finite pointed sets $S_* \to S'_*$ (which we will also denote by $\alpha$) together with a linear ordering $\preceq_{s', s'}$ of $\alpha^{-1}\{s'\}$ for each $s' \in S'$. Let $I$ be defined as in (b). As a map of pointed finite sets, $f(\alpha)$ is given by the composite map

$$I_* \hookrightarrow (S \times \{8\})_* \to S_* \overset{\alpha}{\to} S'_*.$$ 

For each $s' \in S'$, we define a linear ordering $\preceq_{f(\alpha),s'}$ on $f(\alpha)^{-1}\{s'\}$ as in (c).
Let \( p : \text{Tens}^\otimes \to N(\text{Fin}_*) \) and \( p' : \text{Ass}^\otimes \to N(\text{Fin}_*) \) denote the forgetful functors. We define a natural transformation \( \iota : p' \circ f \to p \) between functors \( \text{Tens}^\otimes \to N(\text{Fin}_*) \) as follows:

- On objects \((S_*, c_-, c_+) \in \text{Tens}^\otimes \times \Delta^1 \{1\} \), \( \iota \) is given by the identity map from \( S_* \) to itself.
- On objects \((S_*, c_-, c_+) \in \text{Tens}^\otimes \times \Delta^1 \{0\} \), \( \iota \) is given by the composite map

\[
I_* \mapsto (S \times [8])_* \to S_*
\]

where \( I \) is defined as in (b).

Let \( q : \mathcal{C}^\otimes \to N(\text{Fin}_*) \) exhibit \( \mathcal{C}^\otimes \) as a symmetric monoidal \( \infty \)-category, and let \( A \) be an algebra object of \( \mathcal{C} \). Then we can lift \( \iota \) to a \( q \)-coCartesian natural transformation \( A \circ f \to A' \) between functors from \( \text{Tens}^\otimes \to \mathcal{C}^\otimes \). Unwinding the definitions, we see that the restriction of \( A' \) to \( \text{Tens}^\otimes \times \Delta^1 \{0\} \) encodes the pair of bimodules

\[
A \boxtimes A^e \in \mathcal{A} \text{BMod}_{A \otimes A^e \otimes A}^{\otimes \mathcal{A}}(\mathcal{C}) \quad A^e \boxtimes A \in \mathcal{A} \otimes \text{BMod}_A^{\otimes \mathcal{A}} (\mathcal{C}),
\]

and that the restriction of \( A' \) to \( \text{Tens}^\otimes \times \Delta^1 \{1\} \) gives the bimodule object of \( \mathcal{C} \) determined by \( A \) (regarded as a bimodule over itself). Consequently, \( A' \) determines a map of bimodules

\[
(A \boxtimes A^e) \circ \otimes^{\otimes \mathcal{A}}_{A \otimes A^e \otimes A} (A^e \boxtimes A) \to A.
\]

We will complete the proof by showing that this map is an equivalence: that is, the map \( A' \) is an equivalence in \( \text{BMod}_{A \otimes A^e \otimes A}^{\otimes \mathcal{A}}(\mathcal{C}) \). Let \( U_+ : N(\Delta_+)^{op} \to \text{Tens}^\otimes \) be defined as in Notation 4.4.2.4. According to Proposition 4.4.2.5, it will suffice to verify that the composition \( A' \circ U_+ : N(\Delta_+)^{op} \to \mathcal{C}^\otimes \) is an operadic \( q \)-colimit diagram.

Let \( u : N(\Delta_+)^{op} \to N(\text{Fin}_*) \) denote the constant map taking the value \((1) \in N(\text{Fin}_*) \). There is unique natural transformation \( \gamma : q \circ A' \circ U_+ \to u \) which carries each object of \( N(\Delta_+)^{op} \) to an active morphism in \( N(\text{Fin}_*) \). Choose a \( q \)-coCartesian natural transformation \( A' \circ U_+ \to B \) lifting \( \gamma \), so that \( B \) is an augmented simplicial object of the \( \infty \)-category \( \mathcal{C} \). Using Propositions 3.1.1.15 and 3.1.1.16, we are reduced to proving that \( B \) is a colimit diagram in \( \mathcal{C} \).

Let \( \mathcal{J} \) denote the subcategory of \( \Delta \) containing all objects, whose morphisms are order-preserving maps \( \alpha : [m] \to [n] \) satisfying \( f(0) = 0 \) and \( f(m) = n \). Let \( \text{Cut} : N(\mathcal{J})^{op} \to \text{Ass}^\otimes \) be as in Construction 4.1.2.5, and let \( \text{Cut}_0 = \text{Cut} \mid N(\mathcal{j})^{op} \). Then \( \text{Cut}_0 \) carries each morphism in \( \mathcal{J} \) to an active morphism in \( \text{Ass}^\otimes \).

Consequently, there is a natural transformation \( \delta \) from \( p' \circ \text{Cut}_0 \) to the constant functor \( N(\mathcal{j})^{op} \to N(\text{Fin}_*) \) taking the value \((1) \), uniquely determined by the requirement that \( \delta \) carries each object of \( N(\mathcal{j})^{op} \) to an active morphism in \( N(\text{Fin}_*) \). Choose a \( q \)-coCartesian natural transformation \( A \circ \text{Cut}_0 \to B' \) of functors from \( N(\mathcal{j})^{op} \to \mathcal{C}^\otimes \), so that we can regard \( B' \) as a functor from \( N(\mathcal{j})^{op} \) into \( \mathcal{C} \). Informally, \( B' \) is given by the formula \( B'(\mathcal{n}) = \mathcal{A} \otimes \mathcal{C}^n \).

Unwinding the definitions, we see that the functor \( B \) is equivalent to the composition

\[
N(\Delta_+)^{op} \xrightarrow{\epsilon} N(\mathcal{j})^{op} \xrightarrow{B'} \mathcal{C},
\]

where \( \epsilon \) is induced by the functor \( \Delta_+ \to \mathcal{J} \) given by \( I \mapsto [0] \star I \star I^{op} \star I \star [0] \). We are therefore reduced to proving that \( B' \circ \epsilon \) is a colimit diagram.

Let \( \epsilon' : N(\Delta_+)^{op} \times N(\Delta_+)^{op} \to N(\mathcal{j})^{op} \) be the functor induced by the formula \( (I, J) \mapsto [0] \star I \star I^{op} \star J \star [0] \), so that \( \epsilon \) is given by composing \( \epsilon' \) with the diagonal map \( N(\Delta_+)^{op} \to N(\Delta_+)^{op} \times N(\Delta_+)^{op} \). Let \( \mathcal{X} \) denote the full subcategory of \( N(\Delta_+)^{op} \times N(\Delta_+)^{op} \) spanned by those pairs \((i, [i]) \) where either \( i, j \geq 0 \), or \( i = j = [-1] \). Then \( \mathcal{X} \simeq (N(\Delta_+)^{op})^\circ \). Since \( N(\Delta_+)^{op} \) is sifted, \( B' \circ \epsilon \) is a colimit diagram if and only if \( B' \circ (\epsilon' \mid \mathcal{X}) \) is a colimit diagram.

Note that for each \( i \geq 0 \), the restriction of \( \epsilon' \) to \( \{[i] \times N(\Delta_+)^{op} \) extends to a split augmented simplicial object of \( N(\mathcal{j})^{op} \), so that \( B' \circ (\epsilon' \mid [i] \times N(\Delta_+)^{op} \) is a colimit diagram in \( \mathcal{C} \). It follows that \( B' \circ (\epsilon' \mid N(\Delta_+)^{op} \times N(\Delta_+)^{op} \) is a left Kan extension of \( B' \circ (\epsilon' \mid N(\Delta_+)^{op} \times N(\Delta_+)^{op} \). Using Lemma T.4.3.2.7, we are reduced
to proving that the restriction $B' \circ e'((\mathbf{N}(\Delta))^\text{op} \times \mathbf{N}(\Delta_+)^\text{op})^d$ is a colimit diagram. Since the inclusion $\mathbf{N}(\Delta)^\text{op} \times \{[-1]\} \hookrightarrow \mathbf{N}(\Delta)^\text{op} \times \mathbf{N}(\Delta_+)^\text{op}$ is left cofinal, we are reduced to proving that the restriction $B' \circ e' \mathbf{N}(\Delta_+)^\text{op} \times \{[-1]\}$ is a colimit diagram in $\mathcal{C}$. We now observe that this diagram is given by

$$I \mapsto B'(((0 \star I) * ([0] \star I))^\text{op}),$$

and is therefore a split augmented simplicial object of $\mathcal{C}$. □

### 4.6.4 Smooth and Proper Algebras

Throughout this section, we fix a symmetric monoidal $\infty$-category $\mathcal{C}$ satisfying the following condition:

- The $\infty$-category $\mathcal{C}$ admits geometric realizations of simplicial objects, and the tensor product functor $\boxtimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves geometric realizations of simplicial objects.

Let $A$ be an algebra object of $\mathcal{C}$, and let $M$ be a left $A$-module. Then we can identify $M$ with an object of $\mathcal{A}_{\text{BMod}}_1(\mathcal{C})$, where $1$ denotes a unit algebra object of $\mathcal{C}$ (Corollary 4.3.2.8). In §4.6.2, we introduced two natural finiteness conditions on $M$:

(a) The condition that $M$ be a right dualizable object of $\mathcal{A}_{\text{BMod}}_1(\mathcal{C})$. According to Proposition 4.6.2.13, this condition is independent of the action of $A$ on $M$: it is equivalent to the requirement that $M$ be dualizable when viewed as an object of the symmetric monoidal $\infty$-category $\mathcal{C}$ (see §4.6.1).

(b) The condition that $M$ be a left dualizable object of $\mathcal{A}_{\text{BMod}}_1(\mathcal{C})$: that is, that $M$ admit an $A$-linear dual.

In general, these conditions are not related to one another. For example, the object $A \in \mathcal{L}_{\text{Mod}}_A(\mathcal{C})$ is always left dualizable (Example 4.6.2.5), but is right dualizable if and only if $A$ is dualizable as an object of $\mathcal{C}$. In this section, we will introduce conditions on $A$ which guarantee that (a) implies (b) and vice-versa.

**Remark 4.6.4.1.** The finiteness conditions we introduce in this section are have been well-studied in the setting of differential graded algebras over a commutative ring. We refer the reader to [148] for an introduction.

**Definition 4.6.4.2.** Let $A$ be an algebra object of $\mathcal{C}$. We will say that $A$ is *proper* if it is dualizable when regarded as an object of $\mathcal{C}$.

**Remark 4.6.4.3.** Let $A$ be an algebra object of $\mathcal{C}$. The condition that $A$ is proper depends only on the image of $A$ under the forgetful functor $\mathbf{Alg}(\mathcal{C}) \to \mathcal{C}$. In particular, $A$ is proper if and only if the opposite algebra $A^{rev}$ is proper.

The condition that an algebra object $A \in \mathbf{Alg}(\mathcal{C})$ be proper admits many characterizations:

**Proposition 4.6.4.4.** Let $A$ be an algebra object of $\mathcal{C}$. The following conditions are equivalent:

1. The algebra object $A$ is proper.
2. The coevaluation module $A^e \in \mathcal{A}_{\text{BMod}} A^{rev} \otimes A(\mathcal{C})$ is left dualizable.
3. The evaluation module $A^e \in \mathcal{A}_{\otimes A^{rev}} \mathcal{B}_{\text{Mod}}_1(\mathcal{C})$ is right dualizable.
4. Let $B$ and $C$ be algebra objects of $\mathcal{C}$, and let $M \in \mathcal{A}_{\otimes B} \mathcal{B}_{\text{Mod}}_C(\mathcal{C})$ be left dualizable. Then $\sigma_{A,B,C}(M) \in \mathcal{B}_{\text{Mod}} A^{rev} \otimes C(\mathcal{C})$ is also left dualizable, where $\sigma_{A,B,C}$ is defined as in Construction 4.6.3.9.
5. Let $B$ and $C$ be algebra objects of $\mathcal{C}$, and let $N \in \mathcal{B}_{\text{Mod}} A^{rev} \otimes C(\mathcal{C})$ be right dualizable. Then $\tau_{A,B,C}(N) \in \mathcal{A}_{\otimes B} \mathcal{B}_{\text{Mod}}_C(\mathcal{C})$ is right dualizable, where $\tau_{A,B,C}$ is defined as in Construction 4.6.3.9.
(6) Let $B$ be an algebra object of $\mathcal{C}$, and let $M \in \text{LMod}_{A \otimes B}(\mathcal{C})$. If $M$ is left dualizable (that is, $M$ is left dualizable as an object of $A \otimes B \text{BMod}_1(\mathcal{C})$) then its image in $\text{LMod}_B(\mathcal{C}) \simeq B \text{BMod}_1(\mathcal{C})$ is left dualizable.

(7) Let $C$ be an algebra object of $\mathcal{C}$, and let $N \in \text{RMod}_{A^{rev} \otimes C}(\mathcal{C})$. If $N$ is right dualizable (that is, if $N$ is right dualizable as an object of $1 \text{BMod}_{A^{rev} \otimes C}(\mathcal{C})$) then its image in $\text{RMod}_C(\mathcal{C}) \simeq 1 \text{BMod}_C(\mathcal{C})$ is right dualizable.

(8) The forgetful functor $\text{LMod}_A(\mathcal{C}) \to \mathcal{C}$ carries (left) dualizable objects of $\text{LMod}_A(\mathcal{C})$ to dualizable objects of $\mathcal{C}$.

(9) The forgetful functor $\text{RMod}_{A^{rev}}(\mathcal{C}) \to \mathcal{C}$ carries (right) dualizable objects of $\text{RMod}_{A^{rev}}(\mathcal{C})$ to dualizable objects of $\mathcal{C}$.

**Proof.** We will show that $(1) \Rightarrow (2) \Rightarrow (4) \Rightarrow (6) \Rightarrow (8) \Rightarrow (1)$; the implications $(1) \Rightarrow (3) \Rightarrow (5) \Rightarrow (7) \Rightarrow (9)$ follow by the same argument. The implication $(1) \Rightarrow (2)$ follows from Proposition 4.6.2.13, the implication $(4) \Rightarrow (6)$ follows from Proposition 4.6.2.13 and Remark 4.6.3.10, the implication $(6) \Rightarrow (8)$ is obvious, and the implication $(8) \Rightarrow (1)$ follows from the observation that $A$ is left dualizable when viewed as an object of $\text{LMod}_A(\mathcal{C})$ (see Example 4.6.2.5). We will complete the proof by showing that $(2) \Rightarrow (4)$. Suppose that the coevaluation module $A^c$ is left dualizable, and let $M \in A \otimes B \text{BMod}_C(\mathcal{C})$ be left dualizable. Using Remark 4.6.3.5 and Example 4.6.2.15, we deduce that $A^c \boxtimes B \in B \text{BMod}_{A^{rev} \otimes A \otimes B}(\mathcal{C})$ and $A^{rev} \boxtimes M \in A^{rev} \otimes A \otimes B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C})$ are left dualizable, so that

$$\sigma_{A,B,C}(M) = (A^c \boxtimes B) \otimes_{A^{rev} \otimes A \otimes B} (A^{rev} \boxtimes M) \in B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C})$$

is left dualizable by Remark 4.6.2.6.

Suppose that $A \in \text{Alg}(\mathcal{C})$ is a proper algebra object. Let $A^\vee$ denote the dual of $A$, as an object of $\mathcal{C}$. Using Proposition 4.6.2.13, we see that the left action of $A$ on itself determines a right action of $A$ on $A^\vee$. Similarly, the right action of $A$ on itself determines a left action of $A$ on $A^\vee$. We will see in a second that these actions are compatible with one another: that is, $A^\vee$ has the structure of an $A$-bimodule object of $\mathcal{C}$.

**Definition 4.6.4.5.** Let $A$ be a proper algebra object of $\mathcal{C}$, so that the coevaluation module

$$A^c \in 1 \text{BMod}_{A^{rev} \otimes A}(\mathcal{C})$$

is left dualizable. We may then identify the left dual of $A^c$ with an object of $A_{rev} \otimes A \text{BMod}_1(\mathcal{C})$. We let $S_A$ denote the image of this object under the equivalence of $\infty$-categories

$$\sigma_{A^{rev},1} : A_{rev} \otimes A \text{BMod}_1(\mathcal{C}) \to A \text{BMod}_A(\mathcal{C})$$

of Construction 4.6.3.9. We will refer to $S_A$ as the **Serre bimodule** of $A$.

More explicitly, the Serre bimodule of a proper algebra $A$ is given by the tensor product

$$(A^c \boxtimes A) \otimes_{A \otimes A^{rev} \otimes A} (A \boxtimes A^{rev^*}),$$

where $A^{rev^*}$ denotes the left dual of $A^c$.

**Remark 4.6.4.6.** Let $A$ be a proper algebra object of $\mathcal{C}$, so that the opposite algebra $A^{rev}$ is also proper (Remark 4.6.4.3). Using Remark 4.6.3.8 and Proposition 4.6.3.15, we obtain a canonical equivalence $S_{A^{rev}} \simeq (S_A)^{rev}$ in $A^{rev} \text{BMod}_{A^{rev}}(\mathcal{C})$. That is, the formation of Serre bimodules is compatible with reversal.

**Remark 4.6.4.7.** Let $A$ be a proper algebra object of $\mathcal{C}$. Then the left dual of the coevaluation bimodule $A^c$ is given by the relative tensor product

$$(S_A \boxtimes A^{rev}) \otimes_{A \otimes A^{rev}} A^c \in A_{rev} \otimes A \text{BMod}_1(\mathcal{C}) \simeq A_{rev} \otimes A \text{BMod}_1(\mathcal{C})$$.
Remark 4.6.4.8. Let \( A \) be a proper algebra object of \( \mathcal{C} \). Then the evaluation module \( A^e \in A \otimes A^{rev} \text{BMod}_1(\mathcal{C}) \) is right dualizable. Let \( S_A' \) denote the image of the right dual of \( A^e \) under the equivalence of \( \infty \)-categories

\[
1 \text{BMod}_{A \otimes A^{rev}}(\mathcal{C}) \simeq 1 \text{BMod}_{A^{rev} \otimes A}(1) \mathcal{C} \rightarrow \text{BMod}_{A}(\mathcal{C}).
\]

Note that the right dual of \( A^e = (A^e)^{rev} \) can be identified with \( M^{rev} \), where \( M \) is the left dual of \( A^e \). Using Remarks 4.6.3.17 and 4.6.4.6 we obtain equivalences \( S_A' \simeq (S_A)^{rev} \simeq S_A \).

Remark 4.6.4.9. Let \( A \) be a proper algebra object of \( \mathcal{C} \), and let \( S_A \in \text{BMod}_1(\mathcal{C}) \) be its Serre bimodule. Using Remark 4.6.3.10 we see that the image of \( S_A \) in \( \text{LMod}_A(\mathcal{C}) \) can be identified with the left dual of \( A \), regarded as right module over itself. Using the alternative characterization of \( S_A \) supplied by Remark 4.6.4.8, we can use the same reasoning to identify the image of \( S_A \) under the forgetful functor \( \text{A\text{BMod}}_1(\mathcal{C}) \rightarrow \text{RMod}_A(\mathcal{C}) \) with the right dual of \( A \), regarded as a left module over itself. More informally: we identify the Serre bimodule \( S_A \) with the dual of \( A \) (regarded as an object of \( \mathcal{C} \)), with a left action of \( A \) induced by the right action of \( A \) on itself, and a right action of \( A \) induced by the left action of \( A \) on itself.

Remark 4.6.4.10. Suppose we are given algebra objects \( A, B, C \in \text{Alg}(\mathcal{C}) \), where \( A \) is proper, and let \( M \in A \otimes B \text{Mod}_C(\mathcal{C}) \) be left dualizable. According to Proposition 4.6.4.4, \( \sigma_{A,B,C}(M) \in B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C}) \) is also left dualizable. Let \( M^*, A^* \), and \( \sigma_{A,B,C}(M)^* \) denote the left duals of \( M \) and \( \sigma_{A,B,C}(M) \), respectively. Using the definition

\[
\sigma_{A,B,C}(M) = (A^e \otimes B) \otimes_{A^{rev} \otimes A \otimes B} (A^e \otimes M)
\]

and invoking Remark 4.6.2.6, we obtain an equivalence

\[
\sigma_{A,B,C}(M)^* \simeq (A^{rev} \otimes M^*) \otimes_{A^{rev} \otimes A \otimes B} (A^e \otimes B)
\]

\[
\simeq (A^{rev} \otimes M^*) \otimes_{A^{rev} \otimes A \otimes B} (A^{rev} \otimes S_A \otimes B) \otimes_{A^{rev} \otimes A \otimes B} ((A^{rev})^e \otimes B)
\]

\[
\simeq (A^{rev} \otimes (M^* \otimes_{A \otimes B} (S_A \otimes B))) \otimes_{A^{rev} \otimes A \otimes B} ((A^{rev})^e \otimes B)
\]

\[
\simeq \tau_{A^{rev},C,B}(M^* \otimes_{A \otimes B} (S_A \otimes B)).
\]

Example 4.6.4.11. Let \( A \) be a proper algebra object of \( \mathcal{C} \), and let \( M \in \text{LMod}_A(\mathcal{C}) \simeq A \text{BMod}_1(\mathcal{C}) \). Note that Proposition 4.6.3.18 supplies an equivalence \( M^{rev} \simeq \sigma_{A,1,1}(M) \). If \( M \) is left dualizable, then \( M^{rev} \) is also left dualizable. Let us denote their left duals by \( \check{\vee} M \) and \( \check{\vee} M^{rev} \). In this case, \( M \) is also right dualizable, with right dual given by \( (\check{\vee} M^{rev})^{rev} \). Remark 4.6.4.10 supplies an equivalence \( \check{\vee} M^{rev} \simeq (M^* \otimes_A S_A)^{rev} \), so that the right dual of \( M \) can be identified with \( \check{\vee} M \otimes_A S_A \) as an object of \( \text{RMod}_A(\mathcal{C}) \).

We next consider a finiteness condition on algebra objects which is in some sense dual to Definition 4.6.4.2.

Proposition 4.6.4.12. Let \( A \) be an algebra object of \( \mathcal{C} \). The following conditions are equivalent:

1. The coevaluation module \( A^e \in 1 \text{BMod}_{A^{rev} \otimes A}(\mathcal{C}) \) is right dualizable.
2. The evaluation module \( A^e \in A \otimes A^{rev} \text{BMod}_1(\mathcal{C}) \) is left dualizable.
3. Let \( B \) and \( C \) be algebra objects of \( \mathcal{C} \), and let \( M \in A \otimes B \text{Mod}_C(\mathcal{C}) \) be right dualizable. Then \( \sigma_{A,B,C}(M) \in B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C}) \) is also right dualizable, where \( \sigma_{A,B,C} \) is defined as in Construction 4.6.3.9.
4. Let \( B \) and \( C \) be algebra objects of \( \mathcal{C} \), and let \( N \in B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C}) \) be left dualizable. Then \( \tau_{A,B,C}(N) \in A \otimes B \text{Mod}_C(\mathcal{C}) \) is left dualizable, where \( \tau_{A,B,C} \) is defined as in Construction 4.6.3.9.
5. Let \( C \) be an algebra object of \( \mathcal{C} \), and let \( N \in \text{RMod}_{A^{rev} \otimes C}(\mathcal{C}) \). If the image of \( N \) in \( \text{RMod}_C(\mathcal{C}) \) is right dualizable, then \( N \) is right dualizable.
6. Let \( B \) be an algebra object of \( \mathcal{C} \), and let \( M \in \text{LMod}_{A \otimes B}(\mathcal{C}) \). If the image of \( M \) in \( \text{LMod}_B(\mathcal{C}) \) is left dualizable, then \( M \) is left dualizable.
Proof. The equivalence of (1) and (2) is clear (since $A^c = (A^c)^{\text{rev}}$ by definition). We will show that (1) $\Rightarrow$ (3) $\Rightarrow$ (5) $\Rightarrow$ (1); the same argument will show that (2) $\Rightarrow$ (4) $\Rightarrow$ (6) $\Rightarrow$ (2).

Suppose first that (1) is satisfied, so that $A^c$ is right dualizable. Let $M \in A \otimes B \text{BMod}_C(\mathcal{C})$ be right dualizable. Using Remark 4.6.2.5 and Example 4.6.2.15, we deduce that $A^c \otimes B \in B \text{BMod}_{A^c \otimes A \otimes B}(\mathcal{C})$ and $A^c \otimes M \in A^c \otimes A \otimes B \text{BMod}_{A^c \otimes C}(\mathcal{C})$ are right dualizable, so that

$$\sigma_{A^c, A^c}(M) = (A^c \otimes B) \otimes_{A^c \otimes A \otimes B} (A^c \otimes M) \in B \text{BMod}_{A^c \otimes C}(\mathcal{C})$$

is right dualizable by Remark 4.6.2.6. This proves (3).

The implication (3) $\Rightarrow$ (5) follows from Proposition 4.6.2.13 and Remark 4.6.3.10 (take $B = 1$). Now suppose that (5) is satisfied; we wish to show that the coevaluation module $A^c$ is a right dualizable object of $1 \text{BMod}_{A^c}(1)$. Using (5), we are reduced to showing that the image of $A^c$ in $1 \text{BMod}_A(\mathcal{C})$ is right dualizable: that is, that $A$ is dualizable when viewed as a right module over itself. This follows from Example 4.6.2.5.

\begin{flushright}
$\square$
\end{flushright}

**Definition 4.6.13.** Let $A$ be an algebra object of $\mathcal{C}$. We will say that $A$ is **smooth** if the equivalent conditions of Proposition 4.6.4.12 are satisfied.

\begin{flushright}
$\square$
\end{flushright}

**Remark 4.6.4.14.** The terminology introduced in Definitions 4.6.4.2 and 4.6.4.13 is motivated by algebraic geometry. Let $\kappa$ be a field. The collection of chain complexes of vector spaces over $\kappa$ can be organized into an infinite-category (see §1.3.1) which we will denote by $d\text{Vect}_\kappa$. Tensor product over $\kappa$ endows $d\text{Vect}_\kappa$ with a symmetric monoidal structure (Proposition 7.1.2.11). Let $X$ be a quasi-projective variety defined over a field $\kappa$. Then the collection of complexes of quasi-coherent sheaves on $X$ can be organized into a stable infinite-category, which we will denote by $\text{QCoh}(X)$. One can show that the infinite-category $\text{QCoh}(X)$ always has the form $L\text{Mod}_A(d\text{Vect}_\kappa)$, where $A$ is an associative algebra object of $d\text{Vect}_\kappa$ (for example, if $X$ is an affine variety, we can take $A$ to be the ring of functions on $X$). One can show that $A$ is proper (in the sense of Definition 4.6.4.2) if and only if the variety $X$ is proper, and that $A$ is smooth (in the sense of Definition 4.6.4.13) if and only if $X$ is smooth.

**Remark 4.6.4.15.** Let $A$ be an algebra object of $\mathcal{C}$. Then $A$ is smooth if and only if the opposite algebra $A^{rev}$ is smooth (this follows immediately from Remark 4.6.3.8).

**Definition 4.6.4.16.** Let $A$ be a smooth algebra object of $\mathcal{C}$, so that the coevaluation module

$$A^c \in 1 \text{BMod}_{A^{rev} \otimes A}(\mathcal{C})$$

is right dualizable. We may then identify the right dual of $A^c$ with an object of $A^{rev} \otimes A \text{BMod}_1(\mathcal{C})$. We let $T_A$ denote the image of this object under the equivalence of infinite-categories

$$\sigma_{A^{rev} \otimes A, 1} : A^{rev} \otimes A \text{BMod}_1(\mathcal{C}) \to A \text{BMod}_1(\mathcal{C})$$

of Construction 4.6.3.9. We will refer to $T_A$ as the **dual Serre bimodule** of $A$.

**Remark 4.6.4.17.** Let $A$ be a smooth algebra object of $\mathcal{C}$, so that the opposite algebra $A^{rev}$ is also smooth. Using Remark 4.6.3.8 and Proposition 4.6.3.15, we obtain a canonical equivalence $T_A^{rev} \simeq (T_A)^{rev}$ in $A^{rev} \text{BMod}_{A^{rev}}(\mathcal{C})$. That is, the formation of dual Serre bimodules is compatible with reversal.

**Remark 4.6.4.18.** Suppose we are given algebra objects $A, B, C \in \text{Alg}(\mathcal{C})$, where $A$ is smooth, and let $M \in A \otimes B \text{BMod}_C(\mathcal{C})$ be right dualizable. Then the bimodule $\sigma_{A, B, C}(M) \in B \text{BMod}_{A^{rev} \otimes C}(\mathcal{C})$ is also right dualizable. Let $M^*$ and $\sigma_{A, B, C}(M)^*$ denote the right duals of $M$ and $\sigma_{A, B, C}(M)$, respectively. Arguing as in Remark 4.6.4.10, we obtain a canonical equivalence

$$\sigma_{A, B, C}(M)^* \simeq \tau_{A^{rev}, C, B}(M^* \otimes_{A \otimes B} (S_A \otimes B)).$$
4.6. DUALITY

Example 4.6.4.19. Let $A$ be a smooth algebra object of $\mathcal{C}$, and let $M \in \text{LMod}_A(\mathcal{C})$ be a left $A$-module which is dualizable when regarded as an object of $\mathcal{C}$. According to Proposition 4.6.2.13, $M$ is right dualizable when regarded as an object of $\text{A BMod}_A(\mathcal{C})$. Let us denote its right dual by $M^\vee \in \text{BMod}_A(\mathcal{C})$. Since $A$ is smooth, $M$ is also left dualizable. Moreover, the left dual of $M$ is given by $N^\ast$, where $N$ is a right dual of $M^\ast = \sigma_{1,1}(M)$. Using Remark 4.6.4.18, we see that the left dual of $M$ can be identified with $M^\vee \otimes_A T_A$, where $T_A$ is the dual Serre bimodule of Definition 4.6.4.16.

If $A \in \text{Alg}(\mathcal{C})$ is both smooth and proper, then the bimodules $S_A$ and $T_A$ are closely related:

Proposition 4.6.4.20. Let $A$ be an algebra object of $\mathcal{C}$ which is both smooth and proper. Then the bimodules $S_A, T_A \in \text{A BMod}_A(\mathcal{C})$ are inverse to one another (as objects of the monoidal $\infty$-category $\text{A BMod}_A(\mathcal{C})$). That is, we have equivalences

$$ S_A \otimes_A T_A \simeq A \simeq T_A \otimes_A S_A $$

in the $\infty$-category $\text{A BMod}_A(\mathcal{C})$. In particular, $S_A$ and $T_A$ are invertible objects of $\text{A BMod}_A(\mathcal{C})$.

Proof. Since $A$ is smooth and proper, the evaluation and coevaluation modules $A^e$ and $A^c$ are both right dualizable. Let us denote their right duals by $A^e^\ast$ and $A^c^\ast$, respectively. Using Proposition 4.6.3.12 and Remark 4.6.2.6, we deduce that the tensor product $(A^e^\ast \boxtimes A) \otimes_{A \boxtimes A^c^\ast} (A \boxtimes A^c^\ast)$ is equivalent to $A$. Invoking the definitions (and Remark 4.6.4.8), we obtain equivalences

$$ A^e^\ast \simeq (A^e^\ast \boxtimes T_A) \otimes_{A \boxtimes A^c^\ast} (A^e^\ast)^e \quad A^e^\ast \simeq (A^e^\ast)^c \otimes_{A \boxtimes A^c^\ast} (S_A \boxtimes A^e^\ast). $$

We therefore obtain equivalences

$$ A \simeq (A^e^\ast \boxtimes A) \otimes_{A \boxtimes A^c^\ast} (A \boxtimes A^c^\ast) $$

$$ \simeq ((A^e^\ast)^c \boxtimes A) \otimes_{A \boxtimes A^c^\ast} (S_A \boxtimes A^e^\ast) \otimes_{A \boxtimes A^c^\ast} (A \boxtimes A^c^\ast) \otimes_{A \boxtimes A^c^\ast} (T_A) \simeq T_A \otimes_A (A \boxtimes (A^e^\ast)^c) \otimes_A S_A $$

$$ \simeq S_A \otimes_A T_A $$

in the $\infty$-category $\text{A BMod}_A(\mathcal{C})$. The proof that $T_A \otimes_A S_A \simeq A$ is similar. □

Remark 4.6.4.21. If $\mathcal{C}$ is a symmetric monoidal $\infty$-category satisfying condition $(\ast)$, then we can organize the collection of algebra objects of $\mathcal{C}$ into a symmetric monoidal $(\infty, 2)$-category, in which morphisms are given by bimodule objects of $\mathcal{C}$. The ideas of this section can be generalized: it makes sense to consider smooth and proper objects of an arbitrary symmetric monoidal $(\infty, 2)$-category. For a brief account, we refer the reader to [98].

4.6.5 Frobenius Algebras

Throughout this section, we let $\mathcal{C}$ denote a monoidal $\infty$-category with unit object $1 \in \mathcal{C}$, satisfying the following condition:

$(\ast)$ The $\infty$-category $\mathcal{C}$ admits geometric realizations of simplicial objects, and the tensor product functor $\otimes : \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ preserves geometric realizations of simplicial objects.

Assume for the moment that $\mathcal{C}$ is symmetric monoidal. In §4.6.4, we introduced the theory of smooth and proper algebra objects of $\mathcal{C}$. If $A \in \text{Alg}(\mathcal{C})$, then a left $A$-module $M \in \text{LMod}_A(\mathcal{C}) \simeq \text{A BMod}_1(\mathcal{C})$ is left dualizable if and only if it is right dualizable. In this case, left and right duality generally gives two different objects $\langle M, M' \rangle \in \text{RMod}_A(\mathcal{C})$. In this section, we will study additional structures on $A$, which allow us to identify $\langle M, M' \rangle$ with $M'$ as objects of $\mathcal{C}$.
**Definition 4.6.5.1.** Let $A \in \text{Alg}(\mathcal{C})$ be an algebra object of $\mathcal{C}$, and let $m : A \otimes A \rightarrow A$ be the multiplication on $A$. We will say that a morphism $\lambda : A \rightarrow 1$ is nondegenerate if the composite map

$$A \otimes A \overset{m}{\rightarrow} A \overset{\lambda}{\rightarrow} 1$$

is a duality datum in $\mathcal{C}$.

A Frobenius algebra object of $\mathcal{C}$ is a pair $(A, \lambda)$, where $A$ is an algebra object of $\mathcal{C}$ and $\lambda : A \rightarrow 1$ is a nondegenerate map.

We will sometimes abuse terminology by using the term Frobenius algebra object to refer to an algebra object $A \in \mathcal{C}$ which admits a nondegenerate map $\lambda : A \rightarrow 1$. Our first result gives a characterization of such algebras:

**Proposition 4.6.5.2.** Let $A$ be an algebra object of $\mathcal{C}$. The following conditions are equivalent:

1. The algebra object $A$ can be promoted to a Frobenius algebra object of $\mathcal{C}$. That is, there exists a nondegenerate map $\lambda : A \rightarrow 1$.

2. As an object of $\text{RMod}_A(\mathcal{C}) \simeq \text{BMod}_A(\mathcal{C})$, $A$ is left dualizable. Moreover, its left dual $\vee A \in \text{BMod}_A(\mathcal{C}) \simeq \text{LMod}_A$ is equivalent to $A$, regarded as a left module over itself.

3. As an object of $\text{LMod}_A(\mathcal{C}) \simeq \text{BMod}_1(\mathcal{C})$, $A$ is right dualizable. Moreover, its right dual $A^\vee \in \text{BMod}_A(\mathcal{C}) \simeq \text{RMod}_A$ is equivalent to $A$, regarded a right module over itself.

**Proof.** We will show that (1) $\Leftrightarrow$ (2); the proof that (1) $\Leftrightarrow$ (3) is similar. Suppose first that (1) is satisfied. Let $M \in \text{BMod}_A(\mathcal{C})$ and $N \in \text{BMod}_1(\mathcal{C})$ denote the object $A$, regarded as a right or left module over itself, respectively. Then we can regard $\lambda$ as a map from $M \otimes_A N$ to $1$. Since $\lambda$ is nondegenerate, $A$ is left dualizable when regarded as an object of $\mathcal{C}$. It follows from Proposition 4.6.2.13 that $M$ admits a left dual $\vee M$, so that $\lambda$ classifies a map of left $A$-modules $\theta : N \rightarrow \vee M$. The nondegeneracy of $\lambda$ guarantees that the image of $\theta$ in the $\infty$-category $\mathcal{C}$ is an equivalence. It follows that $\theta$ is an equivalence of left $A$-modules, so that $\lambda$ exhibits $N$ as a left dual of $M$. This proves (2).

Conversely, suppose that condition (2) is satisfied. Then $N$ is a left dual of $M$, so there exists a morphism $\lambda : M \otimes_A N \cong A \rightarrow 1$. It follows from Remark 4.6.2.12 that $\lambda$ is nondegenerate. \qed

**Remark 4.6.5.3.** Suppose that $\mathcal{C}$ is a symmetric monoidal $\infty$-category, and let $A$ be a proper algebra object of $\mathcal{C}$, with Serre bimodule $S_A \in \text{BMod}_A(\mathcal{C})$ (see Definition 4.6.4.5). Using the proof of Proposition 4.6.5.2 and Remark 4.6.4.9, we obtain an equivalence between the following three types of data:

(a) Nondegenerate maps $\lambda : A \rightarrow 1$.

(b) Equivalences $S_A \simeq A$ in the $\infty$-category of left $A$-modules.

(c) Equivalences $S_A \simeq A$ in the $\infty$-category of right $A$-modules.

**Remark 4.6.5.4.** Suppose that $\mathcal{C}$ is a symmetric monoidal $\infty$-category, and let $A$ be a proper algebra object of $\mathcal{C}$ with Serre bimodule $S_A$. Let $\lambda : A \rightarrow 1$ be a morphism of $\mathcal{C}$, which is dual to a morphism $\lambda^\vee : 1 \rightarrow S_A$. Then $\lambda$ is nondegenerate if and only if it exhibits $S_A$ as a free right $A$-module generated by $1$. In this case, we can identify $S_A$ with an object of the fiber product $\text{BMod}_A(\mathcal{C}) \times_{\text{RMod}_A(\mathcal{C})} \{1\}$. Using Corollary 4.8.5.6, we deduce the existence of a morphism $\sigma_A : A \rightarrow A$ in $\text{Alg}(\mathcal{C})$ with the following property: the Serre bimodule $S_A$ is equivalent in $\text{BMod}_A(\mathcal{C})$ to $A$, where the right action of $A$ on itself is the evident one, and the left action of $A$ is via the morphism $\sigma_A$. Since the morphism $\lambda^\vee$ also exhibits $S_A$ as the free left $A$-module generated by $1$, we conclude that $\sigma_A : A \rightarrow A$ is an equivalence of left $A$-modules, and therefore an equivalence of algebra objects of $\mathcal{C}$. In this case, we will refer to $\sigma_A$ as the Serre automorphism of $A$.

**CHAPTER 4. ASSOCIATIVE ALGEBRAS AND THEIR MODULES**
Warning 4.6.5.5. The terminology of Remark 4.6.5.4 is somewhat abusive: if \((A, \lambda)\) is a Frobenius algebra object of a symmetric monoidal \(\infty\)-category \(\mathcal{C}\), then the Serre automorphism \(\sigma_\lambda\) depends not only on \(A\), but also on \(\lambda\). However, the conjugacy class of \(\sigma_\lambda\) (in the automorphism group \(\pi_0 \text{Map}_{\text{Alg}(\mathcal{C})}(A, A)\)) is independent of \(\lambda\).

Remark 4.6.5.6. Assume that \(\mathcal{C}\) is symmetric monoidal, let \((A, \lambda)\) be a Frobenius algebra object of \(\mathcal{C}\), and let \(\sigma_\lambda : A \to A\) be the Serre automorphism of Remark 4.6.5.4. Let \(m_0 : A \otimes A \to A\) denote the multiplication on \(A\), and let \(m_1 : A \otimes A \to A\) denote the multiplication on the opposite algebra \(A^{\text{rev}}\). Unwinding the definitions, we deduce that the diagram

\[
\begin{array}{ccc}
A \otimes A & \xrightarrow{\text{id} \otimes \sigma_\lambda} & A \otimes A \\
\downarrow m_1 & & \downarrow m_0 \\
A & \xrightarrow{\lambda} & A
\end{array}
\]

commutes up to homotopy (in the \(\infty\)-category \(\mathcal{C}\)). Moreover, the commutativity of this diagram characterizes \(\sigma_\lambda\) up to homotopy as a morphism in the underlying \(\infty\)-category \(\mathcal{C}\). We can summarize the situation more informally by writing the equation \(\lambda(ab) = \lambda(b \sigma_\lambda(a))\).

Remark 4.6.5.7. Let \(\mathcal{C}\) be a symmetric monoidal \(\infty\)-category, and let \((A, \lambda)\) be a Frobenius algebra object of \(A\). Then the Serre bimodule \(S_A\) is equivalent to \(A\) when viewed either as a left \(A\)-module or as a right \(A\)-module. However, \(S_A\) need not be equivalent to \(A\) as an \(A\)-bimodule unless the Serre automorphism \(\sigma_\lambda\) is homotopic to the identity (or, more generally, if \(\sigma_\lambda\) is homotopic to an inner automorphism of \(A\); see §5.3.2).

Giving an identification of \(S_A\) with \(A\) as an object of \(A^{\text{BMod}}\) is equivalent to identifying the evaluation module \(A^e \in L\text{Mod}_{A \otimes A^{\text{rev}}} (\mathcal{C})\) of Construction 4.6.3.7 with the left dual of the coevaluation module \(A^c \in R\text{Mod}_{A \otimes A^{\text{rev}}} (\mathcal{C})\). Such an identification is determined by a duality pairing

\(\bar{\lambda} : A^c \otimes_{A \otimes A^{\text{rev}}} A^c \to 1\)

having the property that the composite map

\[A \simeq A^c \otimes_A A^c \to A^c \otimes_{A \otimes A^{\text{rev}}} A^c \xrightarrow{\bar{\lambda}} 1\]
