A heuristic for abelian points on elliptic curves

Barry Mazur, Harvard University
Karl Rubin, UC Irvine

MIT, August 2018
Fix an elliptic curve $E$ over a number field $K$.

**Question**

As $F$ runs through abelian extensions of $K$, how often is \( \text{rank}(E(F)) > \text{rank}(E(K)) \)?

By considering the action of $\text{Gal}(F/K)$ on $E(F) \otimes \mathbb{Q}$, the representation theory of $\mathbb{Q}[\text{Gal}(F/K)]$ shows that it is enough to consider the case where $F/K$ is cyclic.

General philosophy: it’s hard to find $F/K$ abelian with $[F : K]$ large and \( \text{rank}(E(F)) > \text{rank}(E(K)) \).
Growth of ranks: analytic approach

**Question**

As $F$ runs through cyclic extensions of $K$, how often is $\text{rank}(E(F)) > \text{rank}(E(K))$?

Using BSD and the factorization

$$L(E/F, s) = \prod_{\chi : \text{Gal}(F/K) \to \mathbb{C}^\times} L(E, \chi, s)$$

this is equivalent to:

**Question**

As $\chi$ runs through characters of $\text{Gal}(\bar{K}/K)$, how often is $L(E, \chi, 1) = 0$?
Fix $E/\mathbb{Q}$ once and for all, and suppress it from the notation.

**Definition**

For $r \in \mathbb{Q}$, define the (plus) modular symbol $[r] = [r]_E$ by

$$[r] := \frac{1}{2} \left( \frac{2\pi i}{\Omega} \int_{i\infty}^{r} f_E(z) \, dz + \frac{2\pi i}{\Omega} \int_{i\infty}^{-r} f_E(z) \, dz \right) \in \mathbb{Q}$$

where $f_E$ is the modular form attached to $E$, and $\Omega$ is the real period.
Fix $E/\mathbb{Q}$ once and for all, and suppress it from the notation.

**Definition**

For $r \in \mathbb{Q}$, define the (plus) modular symbol $[r] = [r]_E$ by

$$[r] := \frac{1}{2} \left( \frac{2\pi i}{\Omega} \int_{i\infty}^{r} f_E(z) \, dz + \frac{2\pi i}{\Omega} \int_{i\infty}^{-r} f_E(z) \, dz \right) \in \mathbb{Q}$$

where $f_E$ is the modular form attached to $E$, and $\Omega$ is the real period.

**Theorem**

For every primitive even Dirichlet character $\chi$ of conductor $m$,

$$\sum_{a \in (\mathbb{Z}/m\mathbb{Z})^\times} \chi(a) [a/m] = \frac{\tau(\chi)L(E, \overline{\chi}, 1)}{\Omega}.$$
In particular

\[ L(E, \chi, 1) = 0 \iff \sum_{a \in (\mathbb{Z}/m\mathbb{Z})^\times} \chi(a)[a/m] = 0. \]

We want to use statistical properties of modular symbols to predict how often this happens.
In particular

\[ L(E, \chi, 1) = 0 \iff \sum_{a \in (\mathbb{Z}/m\mathbb{Z})^\times} \chi(a)[a/m] = 0. \]

We want to use statistical properties of modular symbols to predict how often this happens.

If \( m \geq 1 \), and \( F/\mathbb{Q} \) is cyclic of conductor \( m \), let

- \( \sigma_{a,m} \in \text{Gal}(\mathbb{Q}(\mu_m)/\mathbb{Q}) \) the automorphism \( \zeta_m \mapsto \zeta_m^a \),
- \( \theta_m := \sum_{a \in (\mathbb{Z}/m\mathbb{Z})^\times} [a/m] \sigma_{a,m} \in \mathbb{Q}[\text{Gal}(\mathbb{Q}(\mu_m)/\mathbb{Q})] \),
- \( \theta_F := \theta_m|_F \in \mathbb{Q}[\text{Gal}(F/\mathbb{Q})] \).
theta elements

In particular

\[ L(E, \chi, 1) = 0 \iff \sum_{a \in (\mathbb{Z}/m\mathbb{Z})^\times} \chi(a)[a/m] = 0. \]

We want to use statistical properties of modular symbols to predict how often this happens.

If \( m \geq 1 \), and \( F/\mathbb{Q} \) is cyclic of conductor \( m \), let

- \( \sigma_{a,m} \in \text{Gal}(\mathbb{Q}(\mu_m)/\mathbb{Q}) \) the automorphism \( \zeta_m \mapsto \zeta_m^a \),
- \( \theta_m := \sum_{a \in (\mathbb{Z}/m\mathbb{Z})^\times} [a/m] \sigma_{a,m} \in \mathbb{Q}[\text{Gal}(\mathbb{Q}(\mu_m)/\mathbb{Q})] \),
- \( \theta_F := \theta_m|_F \in \mathbb{Q}[\text{Gal}(F/\mathbb{Q})] \).

If \( \chi \) is an even character of \( \text{Gal}(F/\mathbb{Q}) \), then

\[ L(E, \chi, 1) = 0 \iff \chi(\theta_F) = 0. \]
We have

$$\theta_F = \sum_{\gamma \in \text{Gal}(F/\mathbb{Q})} c_{F,\gamma}\gamma$$

where

$$c_{F,\gamma} = \sum_{\sigma_{a,m}|F=\gamma} [a/m].$$

How likely is it that $\chi(\theta_F) = 0$?
theta coefficients

We have

$$\theta_F = \sum_{\gamma \in \text{Gal}(F/Q)} c_{F,\gamma} \gamma$$

where

$$c_{F,\gamma} = \sum_{\sigma_{a,m}|F=\gamma} [a/m].$$

How likely is it that $\chi(\theta_F) = 0$?

Example

Suppose $[F : \mathbb{Q}] = p$ is prime, and $\chi : \text{Gal}(F/Q) \to \mathbb{C}^\times$ is nontrivial. The only nontrivial $\mathbb{Q}$-linear relation among the $p$-th roots of unity is that their sum is zero, so

$$\chi(\theta_F) = 0 \iff c_{F,\gamma} = c_{F,\gamma'} \quad \forall \gamma, \gamma' \in \text{Gal}(F/Q).$$
Let $N$ be the conductor of $E$. For every $r \in \mathbb{Q}$, modular symbols satisfy:

- There is a $\delta \in \mathbb{Z}$ independent of $r$ such that $\delta[r] \in \mathbb{Z}$

- $[r] = [r + 1]$ since $f_E(z) = f_E(z + 1)$

- $[r] = [-r]$ by definition

- Atkin-Lehner relation: if $w$ is the global root number of $E$, and $a \alpha' N \equiv 1 \pmod{m}$, then $[a'/m] = w[a/m]$

- Hecke relation: if a prime $\ell \nmid N$ and $a_\ell$ is the $\ell$-th Fourier coefficient of $f_E$, then $a_\ell[r] = [\ell r] + \sum_{i=0}^{\ell-1} [(r+i)/\ell]$
Distribution of modular symbols

Histogram of $\{[a/m] : E = 11A1, m = 10007, a \in (\mathbb{Z}/m\mathbb{Z})^\times \}$
Distribution of modular symbols

Histogram of \([a/m] : E = 11A1, m = 10007, a \in (\mathbb{Z}/m\mathbb{Z})^\times\)
Distribution of modular symbols

Histogram of \( \{[a/m] : E = 11A1, m = 100003, a \in (\mathbb{Z}/m\mathbb{Z})^\times \} \)
Distribution of modular symbols

Histogram of \([a/m] : E = 11A1, m = 100003, a \in (\mathbb{Z}/m\mathbb{Z})^\times\)
Distribution of modular symbols

Histogram of \([a/m] : E = 11A1, m = 1000003, a \in (\mathbb{Z}/m\mathbb{Z})^\times\)
Distribution of modular symbols

Histogram of \([a/m] : E = 11A1, m = 1000003, a \in (\mathbb{Z}/m\mathbb{Z})^\times\)
Distribution of modular symbols

Histogram of \([a/m] : E = 11A1, m = 10000019, a \in (\mathbb{Z}/m\mathbb{Z})^\times\)
Distribution of modular symbols

Histogram of \{[a/m] : E = 11A1, m = 10000019, a \in (\mathbb{Z}/m\mathbb{Z})^\times\}
Distribution of modular symbols

This looks like a normal distribution.
Distribution of modular symbols

This looks like a normal distribution.

How does the variance depend on $m$?
Distribution of modular symbols

Plot of variance vs. $m$, for $E = 11A1$: 

- $\gcd(11, m) = 1$
- $\gcd(11, m) = 11$
Distribution of modular symbols

Plot of variance vs. $m$, for $E = 45A1$:
Distribution of modular symbols

For $m \geq 1$ let $S_m$ denote the data $S_m = \{ [a/m] : a \in (\mathbb{Z}/m\mathbb{Z})^\times \}$.

Conjecture

There is an explicit constant $V_E$ such that

1. as $m \to \infty$, the distribution of the $\frac{1}{\sqrt{\log(m)}} S_m$ converge to a normal distribution with mean zero and variance $V_E$.

2. for every divisor $\kappa$ of $N$, $\lim_{m \to \infty} \lim_{(m,N)=\kappa} \text{Variance}(S_m) - V_E \log(m)$ exists and is finite.
Distribution of modular symbols

For $m \geq 1$ let $S_m$ denote the data $S_m = \{[a/m] : a \in (\mathbb{Z}/m\mathbb{Z})^\times \}$.

**Conjecture**

There is an explicit constant $V_E$ such that

1. as $m \to \infty$, the distribution of the $\frac{1}{\sqrt{\log(m)}} S_m$ converge to a normal distribution with mean zero and variance $V_E$.

2. for every divisor $\kappa$ of $N$, $\lim_{m \to \infty} \frac{\text{Variance}(S_m) - V_E \log(m)}{(m,N)=\kappa}$ exists and is finite.

**Theorem (Petridis-Risager)**

The conjecture above holds if $N$ is squarefree and we average over $m$.

The variance $V_E$ is essentially $L(\text{Sym}^2(E), 1)$, and Petridis & Risager compute the limit in 2 in terms of $L(\text{Sym}^2(E), 1)$ and $L'(\text{Sym}^2(E), 1)$. 
What does this tell us about the distribution of the theta coefficients? If \([F : \mathbb{Q}] = d\), then each theta-coefficient \(c_{F,\gamma}\) is a sum of \(\varphi(m)/d\) modular symbols. We (think we) know how the modular symbols are distributed, but are they independent? If so, then the

\[
\frac{c_{F,\gamma}}{\sqrt{V_E \log(m)(\varphi(m)/d)}}
\]

should satisfy a normal distribution with variance 1.
Distribution of normalized theta coefficients, $d = 3$

$E = 11A1$, primes $m \equiv 1 \pmod{3}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = 3$, $10000 < m < 20000$:

The red curve is the expected normal distribution.
Distribution of normalized theta coefficients, $d = 3$

$E = 11A1$, primes $m \equiv 1 \pmod{3}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = 3$, $20000 < m < 40000$:

The red curve is the expected normal distribution.
Distribution of normalized theta coefficients, \( d = 3 \)

\( E = 11A1, \text{ primes } m \equiv 1 \pmod{3}, L \subset \mathbb{Q}(\mu_m), [L : \mathbb{Q}] = 3, \)

\( 40000 < m < 80000: \)

The red curve is the expected normal distribution.
Distribution of normalized theta coefficients, $d = 3$

$E = 11A1$, primes $m \equiv 1 \pmod{3}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = 3$, $80000 < m < 160000$:

The red curve is the expected normal distribution.
$E = 11A1$, primes $m \equiv 1 \pmod{3}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = 3$, $160000 < m < 320000$:

The red curve is the expected normal distribution.
Distribution of normalized theta coefficients, $d = 3$

$E = 11A1$, primes $m \equiv 1 \pmod{3}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = 3$, $320000 < m < 640000$:

The red curve is the expected normal distribution.
Distribution of normalized theta coefficients, \( d = 3 \)

\( E = 11A1 \), primes \( m \equiv 1 \pmod{3}, \) \( L \subset \mathbb{Q}(\mu_m), [L : \mathbb{Q}] = 3, \)

\( 10000 < m < 640000: \)

The red curve is the expected normal distribution.

The data does seem to be converging (so the scaling factor looks correct), but not to the expected limit.
Distribution of $\theta$-coefficients, small $d$

$E = 11A1$, $m \equiv 1 \pmod{d}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = d$,

$d = 3$
Distribution of $\theta$-coefficients, small $d$

$E = 11A1, m \equiv 1 \pmod{d}, L \subset \mathbb{Q}(\mu_m), [L : \mathbb{Q}] = d,$

$d = 5$
Distribution of $\theta$-coefficients, small $d$

$E = 11A1$, $m \equiv 1 \pmod{d}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = d,$

$d = 7$
Distribution of $\theta$-coefficients, small $d$

$E = 11A1$, $m \equiv 1 \pmod{d}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = d$,

$d = 11$
Distribution of $\theta$-coefficients, small $d$

$E = 11A1, m \equiv 1 \pmod{d}, L \subset \mathbb{Q}(\mu_m), [L : \mathbb{Q}] = d,$

$d = 13$
Distribution of $\theta$-coefficients, small $d$

$E = 11A1$, $m \equiv 1 \pmod{d}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = d,$

$d = 17$
Distribution of $\theta$-coefficients, small $d$

$E = 11A1$, $m \equiv 1 \pmod{d}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = d$,

$d = 23$
Distribution of $\theta$-coefficients, small $d$

$E = 11A1, m \equiv 1 \pmod{d}, L \subset \mathbb{Q}(\mu_m), [L : \mathbb{Q}] = d,$

$d = 31$
Distribution of $\theta$-coefficients, small $d$

$E = 11A1$, $m \equiv 1 \pmod{d}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = d$,

$d = 41$
Distribution of $\theta$-coefficients, small $d$

$E = 11A1$, $m \equiv 1 \pmod{d}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = d$,

$d = 53$
Distribution of $\theta$-coefficients, small $d$

$E = 11A1$, $m \equiv 1 \pmod{d}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = d$,

$d = 97$
Distribution of $\theta$-coefficients, small $d$

$E = 11A1$, $m \equiv 1 \pmod{d}$, $L \subset \mathbb{Q}(\mu_m)$, $[L : \mathbb{Q}] = d$,

$d = 293$
Suppose $F/\mathbb{Q}$ is a cyclic extension of degree $d$ and conductor $m$.

Very roughly, $\theta_F$ lies in a cube of side $\sqrt{V_E \log(m) \varphi(m)/d}$ in the $d$-dimensional lattice $\mathbb{Z}[\text{Gal}(F/\mathbb{Q})]$.

Suppose $\chi : \text{Gal}(F/\mathbb{Q}) \rightarrow \mu_d$ is a faithful character. Then

$$L(E, \chi, 1) = 0 \iff \theta_F \in \ker(\chi : \mathbb{Z}[\text{Gal}(F/\mathbb{Q})] \rightarrow \mathbb{C}).$$

That kernel is a sublattice of codimension $\varphi(d)$, so we might expect the “probability” that $L(E, \chi, 1) = 0$ should be about

$$\left( \frac{C_E}{\sqrt{\log(m) \varphi(m)/d}} \right)^{\varphi(d)}$$

for some constant $C_E$.

This goes to zero very fast as $d$ and $m$ grow.
This isn’t quite right:

- The previous argument ignores the Atkin-Lehner relation, which “pairs up” the coefficients and forces $\theta_F$ into a sublattice of $\mathbb{Z}[\text{Gal}(F/\mathbb{Q})]$ with rank approximately $d/2$. Taking this into account changes the expectation to

$$\left( \frac{C_E d}{\log(m)\varphi(m)} \right)^{\varphi(d)/4} \cdot$$
Oversimplified picture

This isn’t quite right:

- The previous argument ignores the Atkin-Lehner relation, which “pairs up” the coefficients and forces $\theta_F$ into a sublattice of $\mathbb{Z}[\text{Gal}(F/\mathbb{Q})]$ with rank approximately $d/2$. Taking this into account changes the expectation to

$$
\left( \frac{C_E d}{\log(m)\varphi(m)} \right)^{\varphi(d)/4}.
$$

- The distribution of the (normalized) $\theta_L$ is not uniform in a box, and we don’t fully understand what the correct distribution is. Fortunately, for applications, it doesn’t seem to matter very much what the distribution is, only that there is one and it’s bounded independent of $d$. 

The heuristic

This all leads to the following heuristic estimate:

**Heuristic**

There is a constant $C_E$, depending only on $E$, such that

$$\text{Prob}[L(E, \chi, 1) = 0] \leq \left( \frac{C_E d}{\log(m) \varphi(m)} \right)^{\varphi(d)/4}$$

where $d > 2$ is the order of $\chi$ and $m$ its conductor.

The exponent $\varphi(d)/4$ comes from the assumption that the theta coefficients are independent (except for the Atkin-Lehner relation).
Consequences of the heuristic

Heuristic

\[
\text{Prob}[L(E, \chi, 1) = 0] \leq \left( \frac{C_E d}{\log(m) \varphi(m)} \right) \varphi(d)/4.
\]

Random matrix theory prediction:

RMT prediction (David, Fearnley, Kisilevsky)

For fixed prime \(d\),

\[
\text{Prob}[L(E, \chi, 1) = 0] \approx C_{E,d} \left( \frac{\sqrt{\log(m)}}{m} \right) \varphi(d)/4.
\]

These agree up to power of log.
Consequences of the heuristic

Heuristic

\[
\text{Prob}[L(E, \chi, 1) = 0] \leq \left( \frac{C_E d}{\log(m) \varphi(m)} \right) \varphi(d)/4.
\]

Proposition

*Suppose* \( t : \mathbb{Z}_{>0} \to \mathbb{R}_{\geq 0} \) *is a function, and* \( t(d) \gg \log(d) \). *Then*

\[
\sum_{d : t(d) > 1} \sum_{\chi \text{ order } d} \left( \frac{C_E d}{\log(m) \varphi(m)} \right)^{t(d)} \text{ converges.}
\]

Applying this with \( t(d) = \varphi(d)/4 \) shows

Heuristic

\[
\sum_{d : \varphi(d) > 4} \sum_{\chi \text{ order } d} \text{Prob}[L(E, \chi, 1) = 0] \text{ converges.}
\]
Consequences of the heuristic

This leads to:

**Conjecture**

Suppose $L/\mathbb{Q}$ is an abelian extension with only finitely many subfields of degree 2, 3, or 5 over $\mathbb{Q}$.

Then for every elliptic curve $E/\mathbb{Q}$, we expect that $E(L)$ is finitely generated.
Consequences of the heuristic

This leads to:

**Conjecture**

Suppose $L/\mathbb{Q}$ is an abelian extension with only finitely many subfields of degree 2, 3, or 5 over $\mathbb{Q}$.

Then for every elliptic curve $E/\mathbb{Q}$, we expect that $E(L)$ is finitely generated.

For example, these conditions hold when $L$ is:

- the $\hat{\mathbb{Z}}$-extension of $\mathbb{Q}$,
- the maximal abelian $\ell$-extension of $\mathbb{Q}$, for $\ell \geq 7$,
- the compositum of all of the above.
Consequences of the heuristic

Alternatively:

**Conjecture**

Suppose $E$ is an elliptic curve over $\mathbb{Q}$, and let $M$ denote the compositum of all abelian fields of degree at most 5.

Then $E(\mathbb{Q}^{\text{ab}})/E(M)$ is finitely generated.
Suppose \( d \) is an odd prime. Consider \( F/\mathbb{Q} \) cyclic of degree \( d \) and \( E \) with global root number \(-1\). Then the Atkin-Lehner relation tells us that one of the \( d \) theta coefficients is zero, and the others come in \((d - 1)/2\) pairs \((c, -c)\).

If \( d = 5 \) or \( 7 \) we can plot the \((d - 1)/2\)-tuples of (normalized) theta coefficients. If they are indeed independent, we should get a cloud of data points concentrated near the origin without much other structure.
(In)dependence: star-like structure

Example: $E = 37A1, \ d = 5$
Example: $E = 37A1$, $d = 5$

If we view a point $(x, y)$ as an element $\gamma x + \gamma^2 y - \gamma^3 y - \gamma^4 x \in \mathbb{R}[\text{Gal}(F/Q)]$, then the asymptotes are the lines where one of the 2 complex conjugate pairs of characters vanishes.

In other words, this says that if one of the values $\chi(\theta_F)$ is large, the other has to be small.
Example: $E = 37A1$, $d = 7$
(In)dependence: star-like structure

Example: $E = 37A1, \, d = 7$

In this example the asymptote lines are the lines where **all except one** of the $(d - 1)/2$ pairs of characters vanish.

In other words, if one of the values $\chi(\theta_F)$ is large, all the others seem to be (relatively) small.
When $d = 5$ and the root number is $+1$, then there are 3 (potentially) independent theta coefficients. However, the Hecke relation on the modular symbols says that

$$
\sum_{\gamma} c_{F,\gamma} = \left( \prod_{\ell | m} (a_{\ell} - 2) \right)[0] \ll \sqrt{m}
$$

Since the $c_{F,\gamma}$ have size roughly $\sqrt{m \log(m)}$, this says that the sum of all the theta coefficients is essentially zero for large $m$.

Example: $E = 11A1, d = 5$
Another way to try to measure this phenomenon: Consider the monic polynomial

\[ f_F(x) = x^{(p-1)/2} + c_1 x^{(p-3)/2} + \cdots + c_{(p-1)/2} \]

whose roots are the \((p - 1)/2\) positive real numbers

\[ \frac{|\chi(\theta_F)|^2}{m_\chi \log(m_\chi)} \]

for nontrivial \(\chi\) (note that the \(|\chi(\theta_F)|^2\) are positive, real, conjugate cyclotomic integers).
Another way to try to measure this phenomenon: Consider the monic polynomial

\[ f_F(x) = x^{(p-1)/2} + c_1x^{(p-3)/2} + \cdots + c_{(p-1)/2} \]

whose roots are the \((p - 1)/2\) positive real numbers

\[ |\chi(\theta_F)|^2 \]

\[ m_\chi \log(m_\chi) \]

for nontrivial \(\chi\) (note that the \(|\chi(\theta_F)|^2\) are positive, real, conjugate cyclotomic integers).

The assertion that at most one \(|\chi(\theta_F)|^2\) is ‘large’ is similar to asking that at most one \(c_{n/n}^{1/n}\) is ‘large’.
Extension to other base fields: Suppose now that \( K \) is a number field and \( E \) is an elliptic curve over \( K \). In this case there can be characters \( \chi \) of \( \text{Gal}(\overline{K}/K) \) such that \( L(E, \chi, 1) \) vanishes because of root number considerations.

For all other \( \chi \) we can ask whether

\[
\text{Prob}[L(E, \chi, 1) = 0] \ll \left( \frac{C_E d_\chi}{\log(m_\chi \varphi(m_\chi))} \right)^{\varphi(d_\chi)/4}
\]

(\( * \))

where \( d_\chi \) is the order of \( \chi \) and \( m_\chi \) is the norm of its conductor.
Extensions and generalizations

Extension to other base fields: Suppose now that $K$ is a number field and $E$ is an elliptic curve over $K$. In this case there can be characters $\chi$ of $\text{Gal}(\overline{K}/K)$ such that $L(E, \chi, 1)$ vanishes because of root number considerations.

For all other $\chi$ we can ask whether

$$\text{Prob}[L(E, \chi, 1) = 0] \ll \left(\frac{C_{E(d_\chi)}}{\log(m_\chi)\varphi(m_\chi)}\right)^{\varphi(d_\chi)/4}$$

(*)

where $d_\chi$ is the order of $\chi$ and $m_\chi$ is the norm of its conductor.

(The motivation for (*) depends on the distribution of theta coefficients for abelian extensions $F/K$. Maarten Derickx and Alex Best are currently working to compute these general theta coefficients.)
Conjecture

Suppose $L/K$ is an abelian extension with only finitely many subfields of degree 2, 3, or 5.

Then for every elliptic curve $E/K$, if we exclude those characters that vanish for root number considerations, then we expect $L(E, \chi, 1) = 0$ for only finitely many other characters $\chi$ of $\text{Gal}(L/K)$. 
Conjecture

Suppose $L/K$ is an abelian extension with only finitely many subfields of degree 2, 3, or 5.

Then for every elliptic curve $E/K$, if we exclude those characters that vanish for root number considerations, then we expect $L(E, \chi, 1) = 0$ for only finitely many other characters $\chi$ of $\text{Gal}(L/K)$.

Conjecture

Suppose $L/\mathbb{Q}$ is an abelian extension with only finitely many subfields of degree 2, 3, or 5.

Then for every elliptic curve $E/L$, we expect that $E(L)$ is finitely generated.
Studying $p$-Selmer: Instead of asking how often $L(E, \chi, 1) = 0$, we can ask how often $L(E, \chi, 1)/\Omega_E$ is divisible by (some prime above) $p$. By the Birch & Swinnerton-Dyer conjecture, this should tell us about the $p$-Selmer group $\text{Sel}_p(E/L)$.

It seems reasonable to expect that if the $\theta$-coefficients $c_{L, \chi, g}$ are not all the same (mod $p$), then they are equidistributed (mod $p$).
Extensions and generalizations

Studying $p$-Selmer: Instead of asking how often $L(E, \chi, 1) = 0$, we can ask how often $L(E, \chi, 1)/\Omega_E$ is divisible by (some prime above) $p$. By the Birch & Swinnerton-Dyer conjecture, this should tell us about the $p$-Selmer group $\text{Sel}_p(E/L)$.

It seems reasonable to expect that if the $\theta$-coefficients $c_{L,\chi,g}$ are not all the same (mod $p$), then they are equidistributed (mod $p$).

For example, this leads to the following:

**Conjecture**

Let $S$ be a finite set of rational primes, not containing $p$. Let $L$ be the compositum of the cyclotomic $\mathbb{Z}_\ell$-extensions of $\mathbb{Q}$ for $\ell \in S$. If $E$ is an elliptic curve over $\mathbb{Q}$ whose mod $p$ representation is irreducible, then $\dim_{F_p} \text{Sel}_p(E/L)$ is finite.

The heuristic does not predict finite $p$-Selmer rank when $S$ is infinite.
