LIMITS OF CATEGORIES, AND SHEAVES ON IND-SCHEMES

JONATHAN BARLEV

1. Inverse limits of categories

This notes aim to describe the categorical framework for discussing quasi coherent sheaves and D-modules on certain ind-schemes such as $GR_G, G(O)$ and $G(K)$. Our discussion is somewhat more general than in [1], where only ind-schemes of ind-finite type are discussed (hence $G(O)$ and $G(K)$ are excluded).

1.1. The Data. Throughout these notes, all categories are assumed to Abelian, and possess all direct limits (equivalently arbitrary direct sums). All functors are assumed to commute with direct filtered limits.

The datum we shall deal with is that of $\{C_i\}_{i \in I}$ a filtered, ordered system of categories, where for every $i < j$ we have a pair of adjoint functors $(f_{ji}, g_{ij})$

$$
\begin{array}{cc}
C_i & \xrightarrow{f_{ji}} & C_j \\
g_{ij} & \xleftarrow{} & \\
\end{array}
$$

together with a co-cycle of natural isomorphisms for the compositions of $g$’s:

$$
\begin{array}{cc}
C_i & \xrightarrow{g_{jk} \circ g_{jk}} & C_k \\
g_{ij} & \xleftarrow{} & \\
\end{array}
$$

in turn, via the adjunctions, these give rise to uniquely determined natural transformations for the composition of the $f$’s.

In light of the following examples we shall think of the $f$’s as “going up”, and the $g$’s as “going down”.

Example 1.1.
Let $Y = \lim_{\rightarrow} Y_i$ a presentation of a reasonable strict ind-scheme over $\mathbb{C}$. I.e. $Y_i$'s are schemes, $Y_i \xrightarrow{\iota_i} Y_j$ are closed embeddings, and the ideal of $Y_i$ in $Y_j$ is finitely generated (this is needed to ensure that $!$-pullback exists).

(1) $C_i = \Omega Y_i$ and

$$
\begin{array}{ccc}
\Omega Y_i & \xrightarrow{f_{ji} = \iota_{ji}} & \Omega Y_j \\
& \downarrow{g_{ij} = \iota_{ij}} & \\
\end{array}
$$

Actually even better, just think of an ind-affine scheme, i.e. let $A$ be an abelian, complete, separated topological ring whose topology is generated by a filtered system of open ideals $\{I_i\}$, s.t. $I_i + I_j$ is finitely generated over $I_i \cap I_j$ (In the affine case this assumption can be relaxed); then $C_i = A/I_i \text{-mod.}$

(2) $C_i = D - \text{mod}(Y_i)$, same maps as above.

1.2. **Inverse limits.** To the data $\{C_i, g_{ji}, f_{ij}\}$ one might try to associate four limits; either inverse or inductive and with respect to either $f$‘s or $g$‘s.

Our object of interest is $C := \lim_{\leftarrow} g_{ji} C_i$, this beast is defined by the same universal property that always characterizes inverse limits, this time in the 2-category of categories. It is a category whose objects consist of sequences of “strictly¹ $g_{ji}$-compatible” objects, i.e. a sequence $x_i \in C_i$, and isomorphisms $x_i \cong g_{ij}(x_j)$. Morphisms are sequences of morphisms $\{x_i \rightarrow x'_i\}_{i \in I}$ which are compatible in the sense that following squares commute

$$
\begin{array}{ccc}
x_i & \xrightarrow{g_{ji}(x_j)} & \xrightarrow{g_{ji}(x_j')} x'_i \\
& \downarrow & \downarrow \\
\end{array}
$$

Alternatively, think of $I$ as an index category, and think of $\cup C_i$ as a fibered category over $I$. Then $\lim_{\leftarrow} g_{ji} C_i$ is its category of $g_{ji}$-cartesian sections (cf. the definition of quasi coherent sheaves on algebraic stacks).

$C$ admits component maps $C_i \xrightarrow{g_i} C$ (for $x = (x_i) \in C$, $g_i(x) = x_i$). These are appropriately compatible with $g_{ji}$‘s, i.e. have natural isomorphisms

¹In contrast with lax sequences, where the maps are not required to be isomorphisms.
Example 1.2. In example 1 objects of this inverse limit are often called !-sheaves. When \( Y = \text{spf}A \), this inverse limit is no more than the category of continuous \( A\)-mod’s, which are topologically discrete.

Remark 1.3. \( C \) is an abelian category, and contains all filtered direct limits. In particular, kernels and filtered direct limits are taken termwise, but co-kernels require some more tampering, this is done in 1.6.

1.3. Mapping out of \( C^2 \). The description above makes mapping out of \( C \) easy (as is always the case for inverse limits). Note that so far we have made no use of the \( f \)'s, the role they play is to allow a description of functors out of \( C \).

Proposition 1.4. The functors \( g_i \) admit left adjoints \( f_i \)

\[
\begin{array}{c}
C_i \quad \xrightarrow{f_i} \quad C \\
\xleftarrow{g_i}
\end{array}
\]

Proof. Fix \( i \in I \), in order to define \( f_i \) we must define a \( g_{ji} \) compatible family of functors \( \left( C_i \xrightarrow{(f_i)_j} C_j \right) \) (\( f \)'s components). Indeed, given an object \( x \in C_i \) let

\[
(f_i(x))_j = \lim_{k > i, j} g_{jk} \circ f_{k i}(x)
\]

This is directed by the morphisms, for every \( k' > k \),

\[
g_{jk} \circ f_{ki}(x) \xrightarrow{\text{adjunction}} g_{jk} \circ g_{kk'} \circ f_{k'i}(x) = g_{jk'} \circ f_{k'i}(x)
\]

It is routine to check that objects are \( g_{ji} \) compatible. Defining \( f_i \) on morphisms is straightforward as well.

This subsection is not used until definition 2.8.
Let us show that \((f_i, g_i)\) are adjoint.

\[
\text{Hom}_C(f_i(x_i), (y_j)) = \\
= \lim_{j>i} \text{Hom}_{C_j} \left( \lim_{k>j} g_{jk} \circ f_{ki}(x_i), y_j \right) \\
= \lim_{j>i} \lim_{k>j} \text{Hom}_{C_j} \left( g_{jk} \circ f_{ki}(x_i), y_j \right) \\
= \lim_{k>j} \lim_{k>j} \text{Hom}_{C_j} \left( g_{jk} \circ f_{ki}(x_i), y_k \right) \\
= \text{Hom}_{C_i}(x_i, y_i)
\]

The 4th equality follows from the fact that the Hom-sets in question form a double directed system with respect to \(j\) and \(k\). □

Remark 1.5. The \(f_i\)'s are \(f_{ij}\) compatible, i.e. there exist natural isomorphisms

\[
C_i \xrightarrow{f_i} C_j \xleftarrow{f_j} C
\]

Construction 1.6. We may use 1.4 to construct objects of \(C\) as follows. Given the data of \(c_i \in C_i\) and a compatible family of morphisms\(^3\) \(f_{ji}(c_i) \to c_j\) (equivalently, a compatible family \(c_i \to g_{ij}(c_j)\)), the \((f_i, g_i)\)-adjunction makes \(f_i(c_i)\) a directed system of objects in \(C\), to which we associate the object \(\lim f_i(c_i)\). For instance, this is the method to construct co-kernel in \(C\) from the termwise co-kernels (which are a \(g\)-lax, but not strict, sequence).

Remark 1.7. If it happens that \(f_{ij} \circ g_{ji} \cong 1_{C_i}\) (equivalently \(f_{ij}\) is fully faithfull), as is the case in both the examples in 1.1, then \(f_j : C_i \to C\) simply amounts to taking an object of \(C_j\) \(f^*\#@\)-ing it up along all \(i > j\) and \(g^*\) ing down along all \(i < j\) (cf. exercise 1.2).

Proposition 1.8. For any category \(D\) (satisfying our assumptions) the datum of a functor \(\Phi : C \to D\) is equivalent to that of a collection of functors and a co-cycle of natural isomorphisms

\[
C_i \xrightarrow{f_i} C_j \xleftarrow{\phi_j} D
\]

\(^{3}\text{i.e. a lax f-sequence}\)
That is \( \lim_{←} g_{ji} C_i = C = \lim_{→} f_{ij} C_i \).

**Proof.** Given \( \Phi \), define \( \phi_i = \Phi \circ f_i \), the adjunction is used to show \( f_{ij} \)-compatibility.

Conversely, assume we are given the datum of the \( \phi_i \)'s and natural isomorphisms. Note that for every \( x = (x_i) \in C \) we get a directed system of objects in \( D \) by

\[
\phi_i(x_i) \cong \phi_j \circ f_{ji}(x_i) \rightarrow \phi_j(x_j)
\]

(the last map is given by the adjunction of \( (f_{ij}, g_{ji}) \)). Define \( \Phi(x) = \lim_{→} \phi_j(x_j) \) on objects, and termwise on morphisms.

To complete the claim it remains to present an isomorphisms of functors

\[
\Phi \cong \lim_{→} \phi_j \circ f_i \circ g_i \quad \text{and} \quad \phi_i \cong \lim_{→} \phi_j \circ g_j \circ f_i
\]

Unraveling (and remembering all functors commute with direct limits) Both of these reduce to the existence of

\[
1_C \cong \lim_{→} f_i \circ g_i
\]

We leave this as an exercise in unraveling the definitions and commuting limits. □

**Remark 1.9.** If one is only interested the construction of a functor \( \Phi : C \rightarrow D \), one can relax the requirement in 1.8, that the transformations be isomorphisms, and allow any co-cycle of natural transformations. The same construction is used. Of course, distinct data may now give rise to equivalent functors.

### 1.4. Compactly generated categories.

Next we introduce the notions of compact objects and categories, which simplify the story above. Recall that maps in to inverse limits are easily understood, but mapping out is generally trickier.

**Definition 1.10.** An object \( x \in C \) is called compact if for any directed system of objects the natural map below is an isomorphism

\[
\text{Hom}(x, \lim_{→} x_i) \rightarrow \lim_{→} \text{Hom}(x, x_i)
\]

For a category \( C \), we denote by \( C^c \) it’s full subcategory of compact objects.

**Definition 1.11.** A category \( C \) is called compactly generated if every object in \( C \) is the direct limit of compact objects.

**Example 1.12.** For any quasi-projective scheme \( X \) consider \( \mathcal{Qco}(X) \); it’s compact objects are finitely presented sheaves, and it is compactly generated.

---

4In the sense that is satisfies the appropriate universal property in the 2-category of inductively complete categories and functors which preserve inductive limits.
Observation 1.13.  
(1) A compactly generated category is completely determined by its compact objects in the sense that for any two objects, choosing a limit presentation we may describe their morphisms as well.

\[ \text{Hom}(c, d) = \text{Hom}(\lim c_i, \lim d_j) = \lim \lim (c_i, d_j) \]

(2) If a functor \( F : C \to D \) admits a right adjoint, \( G \), which commutes with direct limits, then \( F \) sends compact objects to compact objects. If \( c \in C \) is compact

\[ \text{Hom}_D(F(c), \lim d_i) = \text{Hom}_C(c, \lim G(d_i)) = \lim \text{Hom}_D(c, G(d_i)) = \lim \text{Hom}_D(F(c), d_i) \]

Now let us return to our system of categories \( \{C_i\} \) and its inverse limit \( C \).

Proposition 1.14. If each \( C_i \) is compactly generated, then so is \( C \). An object in \( C \) is compact iff it is isomorphic to \( f_i(c_i) \) for some \( i \in I \) and \( c_i \in C_i^c \).

Proof. By the observation above, \( f_i \) carries the compact objects of \( C_i \) to compact objects in \( C \). Since \( f_i \) also commutes with direct limits, the image of each \( f_i \) consists of compactly generated objects. As noted in the proof of 1.8, for every \( c \in C \) we have \( c \cong \lim f_i g_i(c) \). This proves the first assertion.

For the second assertion let \( c \in C \) be a compact object. This is the first place we use that \( C_i \) and \( C \) are all abelian categories. Present \( c = \lim f_i(c_i) \) for \( c_i \in C_i^c \), as \( c \) is compact the identity on \( c \) must factor \( c \to f_i(c_i) \to c \) for some \( i \). It follows \( f_i(c_i) = k \oplus c \) for some object \( k \in C \). \( k \) must be compact as well (direct summand of a compact) so the same argument shows there exists a surjection \( f_j(k_j) \to k \), for some \( k_j \in C_j^c \). With out loss of generality (replacing \( i \) and \( j \) by some \( k > i, j \)), we assume \( i = j \) and so obtain a presentation \( f_i(k_i) \xrightarrow{\alpha} f_i(c_i) \to c \to 0 \).

To conclude, note

\[ \text{Hom}_C(f_i(k_i), f_j(c_j)) = \lim_k \text{Hom}_{C_k}(f_{ki}(k_i), f_{kj}(c_j)) \]

\[ = \text{Hom}_{C_i}(k_i, g_i f_j(c_j)) \]

\[ = \lim_k \text{Hom}_{C_i}(k_i, g_i f_j(c_j)) \]

\[ = \lim_k \text{Hom}_{C_k}(f_{ki}(k_i), f_{kj}(c_j)) \]

thus \( \alpha \) comes from some map \( f_{ki}(k_i) \xrightarrow{\alpha_k} f_{kj}(c_j) \). It follows that

\[ c = h_k \left( \text{coker} \left( f_{ki}(k_i) \xrightarrow{\alpha_k} f_{kj}(c_j) \right) \right) \]

hence comes from \( C_k \). \( \square \)
Observation 1.15. The point of all this is that $f_i(c_i)$, for all $c_i \in C_i^c$, generate all the objects in $C$. Hom’s from a compact object considerably, for $c_i \in C_i^c$

$$\text{Hom}_C \left( f_i(c_i), \left( c'_j \right) \right) = \lim_{\kappa} \text{Hom}_{C_k} \left( f_{k_i}(c_i), c'_k \right)$$

so every morphism comes from some “finite stage”. Moreover, in order to define a functor $C \to D$, it suffices to define appropriately compatible functors $C_i^c \to D$.

2. D-modules on infinite type schemes and on ind-schemes

We wish to construct the objects in the title out of D-mod’s on finite type schemes. The “ind” part in the title has essentially been taken care of, e.g. on a finite type ind-scheme, $Y = \lim_i Y_i$ (i.e. $Y_i$ are of finite type over $\mathbb{C}$, e.g. $\text{Gr}_C$), define

$$\text{D-mod}(Y) = \lim_{i'j} \text{D-mod}(Y_i)$$

One could do the same for an arbitrary ind-scheme - if only he could make sense of D-mod($Y_i$), and $i'j$, when the $Y_i$’s are not of finite type. That is the purpose of this section.

2.1. D-mod’s on schemes of infinite type.

Definition 2.1. A scheme $Y$ is called good if it admits a presentation

$$Y = \lim_j Y_j$$

where the $Y_j$’s are schemes of finite type and $Y_j \xrightarrow{\pi_{jk}} Y_k$ is a smooth surjection.

Example 2.2.

1. Any scheme of finite type is good.
2. $\text{spec} \mathbb{C}[x_1, x_2, \ldots] = \lim \mathbb{A}^n$ is good. More generally, for any smooth finite type scheme $X$, the scheme $X[[t]] = \lim X[t]/t^n$ is good, e.g. $G(O)$ is good.
3. A closed subscheme of a good scheme, whose ideal is finitely generated, is good.
4. $\text{spec} \mathbb{C}[[t]]$ is not good (but spf $\mathbb{C}[[t]]$ will be reasonable - the corresponding notion for ind-schemes).

Let $C_i = \text{D-mod}(Y_i)$. Since $\pi_{ij}$ is assumed to be smooth $\pi^*_{ij}$ exists, and we get an inverse system of categories, as in section 1, using the maps

---

5We stress all functors are assumed to commute with direct limits.
The discussion so far has been only in the context of the abelian category, however \( \pi_* \) on this level is unsatisfactory and we shall want to make sense of all this in a derived setting. In fact, all the notions of section 1 make sense for triangulated categories, equipped with DG-models. The issue is choosing which derived categories to use (left or right D-mod's). There is a caveat here and we postpone this point.

2.2. **D-mod operations.** Let \( Y \rightarrow Z \) be a map of good schemes. We show that \( h^* : \text{D-mod}(Y) \rightarrow \text{D-mod}(Z) \) always exists, and discuss when \( h_! \) exists.

**Construction 2.3.** \( h^* : \text{D-mod}(Y) \rightarrow \text{D-mod}(Z) \).

We must construct compatible functors \( \text{D-mod}(Y) \rightarrow \text{D-mod}(Z_i) \). As \( Z_i \) is of finite type, \( h \) factors for \( j \) large enough

\[
Y \xrightarrow{h_j} Z_i \\
\pi_j \downarrow \quad \quad \downarrow h_{ji} \\
Y_j
\]

For such \( j \), we define \( h_{i*} \) as the composition \( \pi_{i*} : \text{D-mod}(Y) \xrightarrow{\pi_{i*}} \text{D-mod}(Y_j) \xrightarrow{h_{ji*}} \text{D-mod}(Z_i) \) (note this does not depend on \( j \), as long as it large enough so the map factors). There exists a co-cycle of natural isomorphisms

\[
\text{D-mod}(Y) \xrightarrow{h_i} \text{D-mod}(Z_i) \\
\pi_{i*} \downarrow \quad \quad \downarrow \pi_{i!*} \\
\text{D-mod}(Z_i)
\]

thus we get our functor \( \text{D-mod}(Y) \xrightarrow{h_*} \text{D-mod}(Z) \). Note that if \( g : Z \rightarrow W \) then \( g_* \circ h_* \cong (g \circ h)_* \).
Also note, on the abelian level $h_!$ is a composition of left exact functors, hence is left exact. $h_*$ is an inverse limit of left exact functors hence also left exact.

In general, $h^!$ will not exist, however we do have the following special case.

**Proposition 2.4.** If $h : Y \hookrightarrow Z$ is a closed embedding, and the ideal of $Y$ in $Z$ is finitely generated; then $h_*$ admits a right adjoint $h^! : \text{D-mod}(Z) \to \text{D-mod}(Y)$.

**Proof.** As this is a local question, assume $Y = \text{spec} A$ and $Z = \text{spec} B$ are affine. Let $Z = \lim_{j \in J} Z_j$ be a presentation of $Z$. In general, there is no reason for $Y$ to have a presentation whose underlying poset is related to that of $Z$. However, in our case we can arrange for both schemes to be presented on the same poset and for the map to “factor through” the presentation as follows. Let $I \subset B$ be the ideal of $Y$ in $Z$, it is finitely generated by assumption; whence we may assume that for all $j$ $I \cap B_j$ generates $I$, where $B_j := \mathcal{O}_{Z_j}$. Certainly $A = B/I = \lim_j B_i/B_i \cap I$, moreover the following square is cartesian by construction

\[
\begin{array}{ccc}
B_i/B_i \cap I & \longrightarrow & B_i \\
\downarrow & & \downarrow \\
B_j/B_j \cap I & \longrightarrow & B_j
\end{array}
\]

implying this is a good presentation of $Y$. Evidently $h = \lim h_i$, where

$$h_i : Y_i := \text{spec} B_i/B_i \cap I \to \text{spec} B_i = Z_i$$

Since for every $i$ we have the adjoint pair

$$\text{D-mod}(Y_i) \xrightarrow{h_i^{-}} \text{D-mod}(Z_i)$$

we are led to define $h^! = \lim_{\leftarrow j} h_i^!$. This is indeed seen to be a right adjoint to $h_*$. \hfill $\square$

**Remark 2.5.** It is obvious from the proof that $h^!$ exists in somewhat greater generality than closed embeddings, i.e. whenever $Y$ and $Z$ may be presented on the same poset, $I$, and the map $h$ factors through this presentation, with cartesian squares as above. For instance this is the case when $Y \xrightarrow{h} Z$ is finitely presented, i.e. factors locally

$$Y \to Z \times \mathbb{A}^n \to Z$$

where the first map has a finitely generated ideal.
2.3. D-mod’s on reasonable ind-schemes. A “reasonable” ind-scheme will be any scheme where the constructions above go through, namely

Definition 2.6. An ind-scheme $Y$ is called reasonable if it admits a presentation

$$Y = \lim_{i} \lim_{j} Y_{ij}$$

where $Y_{ij}$ are schemes of finite type, $Y_{ij} \to Y_{ik}$ is smooth and surjective, and $Y_{i} \to Y_{i'}$ is a closed embedding (of schemes) with locally finitely generated ideal.

For a reasonable ind-scheme $Y$, we define $D\text{-mod}(Y) = \lim_{\iota} D\text{-mod}(Y_{\iota})$. Note we could have defined this category using the universal presentation (using all good closed sub-schemes of $Y$). As any other presentation is co-final in the universal one, the definition does not depend on the presentation.

Example 2.7.

1. Any ind-scheme of ind-finite type is reasonable.
2. $G(K)$ is a reasonable ind-scheme$^6$. To see this recall that $Gr_{G} = G(K)/G(O) = \lim_{i} Z_{i}$, for some finite type schemes $Z_{i}$, let $Y_{i} = Z_{i} \times_{Gr_{G}} G(K)$ it is a closed sub-scheme of $G(K)$. We proceed to show that $G(K) = \lim_{i} Y_{i}$ is a good presentation of $G(K)$. Indeed, $G(O) = \lim_{j} G[t]/t^{j}$, let $G_{j} = \ker (G(O) \to G[t]/t^{j})$ then

$$Y_{i} = \lim_{j} Y_{i}/G_{j}$$

If $j > j'$ then the map $Y_{i}/G_{j} \to (Y_{i}/G_{j})/G_{j'} = Y_{i}/G_{j'}$ is smooth and surjective, hence the presentation of $Y_{i}$ above is good.

Definition 2.8 (De-Rham cohomology). Define the functor $H_{DR}(Y, -) := \lim_{\iota} H_{DR}(Y_{\iota}, -)$ using 1.8, by noting that the latter functors are $\pi_{*}$-compatible.

References

$^6$However, even when $X$ is smooth, $X((t))$ is not always reasonable
